Another example is MTAA's *On Kawara Update*. The work imitates *On Kawara's* black on white oil painting which only have the date it was painted on internet browser. When you click on the date some Google Ads appear on the screen. The work both questions artist labor and it's connection with art market. What happens if a code does all the work? Another feature of the work is that its source code is licensed GNU General Public License and downloadable. So anyone who visits the site has the right to create its own version of this artwork.

Even though it might not be considered as internet art *The Droplift Project* is another interactive experience which attacks intellectual property rights in a Robin Hoodesque way. Müyap in Turkey and RIAA in the US are monopolies on copyrighted music. *The Droplift Project's* website there are more than 20 songs which are composed with the re-use of some copyrighted material like TV show and radio jingles, popular songs etc. They are downloadable and there's also a sticker for album, a front and a back cover with a barcode. You prepare your CD just like the ones sold in big music stores. You go put it in shelf and then wait it to be sold. It's not illegal according to the First Amendment and the Fair Use of the Copyright Act but still the artists can be sued by the copyright owners.

ALTERNATIVE LICENSING

Among this type of re-production, sharing and guerilla activities there are also alternative licenses such as Creative Commons and Copyleft which are widely used in arts and design. Open Source and Open Culture is becoming a part of societies daily part routine. Some articles on Wikipedia can be used as academic resources, Open Access Journalism provides transparent and objective news sources. These systems might create their own spaces of resistance against monopolies.

CULTURE PRODUCTION OF MASS

Slowly but surely commercialized culture is blanced with these models. Cultural production and products seem to circulate more freely. In a society that culture is produced autonomous, it is produced not for the masses but by the masses, everybody is both the author and the hero of this Robin Hood legend.

SCIENCE, ART AND PHILOSOPHY: A REFLECTION ON A METHODOLOGICAL APPROACH TO INTERSEMIOTIC ANALYSIS OF INTERACTIVE INSTALLATIONS

Luiz Antonio Garcia Diniz & Adilson A. J. de Oliveira

We intend to analyze the construction processes of the Installation “*Um Novo Tempo – A New Time*”, created by the Research Group LABI, from the perspective of Yuri Lotman’s reflections on semiotics. Our approach is guided by reflexive relations that lie at the intersection of the concepts of Biosphere and Semiosphere.

Introduction

The vast field of reflection that the analysis of the semiotics of culture proposes allows us to think about cultural objects, in terms of both its immanence and transcendence. This means thinking about the relational forms that such objects have with the culture in general and, particularly, with the aspects of our construction or objective discursivity. In other words, we must discuss the relationship suggested by objects linked to cultural elements which constitute the external semiosphere (Lotman, 1999) and engendered by it, in particular with an eye toward its discursivity to understand the perspective of the Other singularized by the observer subject. Such subject will be defined here as a result of the relationship between the virtual and the actual, erasing boundaries that, as well define Peter Anders, places us in a cybrid environment. Cybridism, a socio-anthropomorphic phenomenon, is quite a clarification of the society in which we live.

Therefore, we have on one hand, the discursivity of the object itself conditioned by its internal laws; while on the other hand, we have the same object inserted into the cultural material of the semiosphere. And finally there is the observer, himself subject to contingencies that gave him the status of singular subject. It should be noted that the schema described above is part of another factor that we believe is important to remember: the link established between these three movements or moments, divergent of suggest stability or permanence of an instance to another, in fact, is made by continuous movement. What we found in an observer/reader interrelationship with the object seen, read and updated by him is a continuous maze of back-and-forth of elements distributed transversally, vertically and especially non-horizontally or linearly.

We will list, then, the elements proposed by the installation of the point of view of its physical structure to look more attentively at their construction procedures in terms of the meanings produced.

A NEW TIME: CONSTRUCTIVE ELEMENTS OF THE INSTALLATION

1-Tablet:

Component of the set below, the tablet, whose purpose is to record a message that is sent to the plans listed above.

2-Joystick device: spatial projection of deferred time

Past, present and future: the same phenomenon in three different perspectives. The interactor being filmed in three image planes: black and white, and red. The device consists of a webcam and a Joystick with five preset keys. Description of keys: access the recent past, access the longer past, access the present, accesses a possible future, change the angle of vision of the planes; Lever: Controls the time units in the second and third cases.

3-Touch Screen: whose choice of six videos shows a phenomenon in its temporality accelerated or extremely slow: the description of the physical phenomenon that occurs in the time interval of the phenomenon (mechanical, hydrostatic, biology). Videos shown: punch, drums, drumsticks, bladder filled with water, flower opening, etc....

4. Clock: aims to show the irreversibility of time. Advancing the clock clockwise, the interacting agent advances the time and, working it counter-clockwise, time is reversed (hair, egg, building falling and glass breaking).

5. Time Machine: temporality browsing media or historical times: Proposal for historicizing time, more specifically, the time in the media related to historical events.

SEMIOTIC SPACES

If we consider semiotic space as a place where semiosis occurs and, if we take as the object of analysis the interactive 'A New Time' installation built at the intersection and articulation of various languages as intersemiotic construction, or even grounded by the fact that these various media that carry distinct meanings produce various significations in their interrelations, and they are managed by the perspective of an interacting organizer, we could deduce that in an interactive installation such as the one proposed for our analysis there is an ensemble of several elements or sets of semiotic elements. However, in our view, it appears to be methodologically important to separate them for analytical purposes and then turn to the production of meaning that the relationships outlined above produce.

The semiotic space, which we will deal specifically with here, is the installation of 'A New Time'. It is necessary, however, to define that space taken up in its particularity in relation to semiosphere as Lotman defines it in his work 'The Semiosphere' (1999). The semiosphere finds conceptually a parallel in the biosphere, space in which all components are networked, making it impossible thus to isolate a single element without breaking the previous balance. It should be noted also the importance of the conceptual proposal to situate it synchronically and not diachronically.

We believe that all concepts involved in the installation go through two discursive instances: the thematic isotopy (abstract) and the figurated. The thematic precedes the figuration in its conception because it works with deeper levels of discourse. It's important to also note that without the passage to the figurative isotopy, we can't think of art, since it operates with consecutive passages of one to another. There were also switches necessary so that the discourse and its meanings are grasped by the enunciatory which, particularly in the object of our study is also the enunciator. The most globally enunciated built by the articulation of thematic and figuratively thematic isotopies only becomes intelligible when the sum of the meanings or interferences/actions added by the interactor participation becomes a constituent of the enunciation.

Exemplifying the way described above, in the installation 'A New Time', the isotopy theme — the plan of content, is made up of different approaches that suggest the concept of time, reversibility, irreversibility, literary time, and media time. The figurative isotopy is the result of the passage of thematic isotopy to the plan of expression; in other words, of constructs figuratized by the installation, for example, the videos about different times and the time machine as a metaphor for the temporality of historical time broadcast by the media.

We consider it important to note that on Lotman's trail of thought on a conceptual side of the semiosphere, it would not be possible to isolate cultural systems, since it comprises the whole of cultural production and the fact that its boundaries are constantly invaded, whether it deals with epistemological, linguistic or theoretical frontiers.

FROM THE SENSIBLE TO THE INTELLIGIBLE: OR HOW TO MAKE THE SIMULACRA – THE FIGURATIZATION OF A MEANS OF CONVEYING A SENSIBLE AND INTELLIGIBLE EXPERIENCE

Can we also consider the installations as simulators of voices that carry meaning? How do we reconcile the aesthesis experience by the induction method of scientific discourse? Or to the so-called scientific knowledge that such facilities are striving to achieve through their own methodology? These are questions to be designed to establish criteria ranging from the strategy of constructing indicative simulations of voices inherent to speech to scientific knowledge itself, narratively established in order to be disclosed to an audience that is not knowledgeable. Easing the transition proposal, that is, one that goes from the sensible to the intelligible is a function of strategy, or a set of strategies that the discursivity of the work proposes.

The installation 'A New Time' suggests the creation of a problem at the representative level interweave in the concept of time. Thus, it proposes a reflection on concepts such as the irreversibility of time, linear time and deferred time. It offers different looks at time or temporalities; thus we can infer from his narrative that the time from the point of view of physics it is different from, but not exclusive to, that which we learn in the more immediate term: we manage to grasp the idea of clock time, manage to place it in daily life but not in that of an action that happened a century ago, for example (unless through history and memory). Bergson (1974, pp. 268) considers that "the science of matter distinguishes a number as large as we would like for the range of moments in time that it considers. As small as intervals that are contained may be, [it] allows us to divide them further if we happened to need to do so." Since natural science always considers virtual time, stopped time is never real time, i.e., the time distinguished (*envisagé*) or as a flow. We would add still some aspects that define the present time in installation, such as literature, the arts and media.

We believe that a short digression fits here to clarify the point of view of the relationship between the three axis of our work located at the interface created by the relationship and links between art, science and philosophy. Therefore, we feel called upon to explain how we approach these forms of knowledge from the perspective of philosophy. To this end, the reflections of Deleuze and Guattari's work 'Qu'est-ce que la philosophie?' (1991) seem extremely important. The dimensions of knowledge, according to the authors, can be seen through the ways in which art, science and philosophy of the approach. The three means or dimensions of knowledge are specific, some as direct as others, and are distinguished by the nature of the plane and what occupies it. To think is therefore to think by concepts, by functions, or by feelings, and none of these thoughts can be considered better or worse than another, or as the au-

thor makes clear, none of them can be supposed to synthesize or express a thought more or less adequately than another. Another factor to consider is that every form of knowledge originates chaos, understood as a virtual space of possibilities. Chaos is not Nothing or absolute disorder, but rather a virtual in that it contains every possibility. Consequently, in the same way that chaos can give rise to forms and concepts, it dissolves them.

Thus, we consider that a see that non-order is processed into a form of knowledge. This form, or systematization of knowledge, provokes your insertion in one of the planes or dimensions mentioned above. Deleuze considers the event as the virtual reality, virtual updated. It is in this sense that the chaos or the virtual event and this allow for updating in the form of an organization of thought. Such an organization will determine the level of knowledge and the binding of the three dimensions that unfold. Basically, the question that pervades the thinking, the 'degree zero' of its birth, is the event [évènement], a phenomenon that gives it form and is processed in the space defined as chaos: virtual space in which the human agent seeks definitions an understanding of the events surrounding it in everyday life.

Therefore, in order to think of time not in linear terms but in its relationship with what was, what is and what will be, the installation proposes, through its enunciates a means of amplifying the concept of time in their simultaneity, i.e. present, past and future in terms of their interrelationships. Such statements seek to address many different readings, such as those quoted above.

DISCOURSE AND DE-COURSE

In accordance with Greimas and Landowski (1984), our approach is based on three forms of speech as typified in the social sciences and, in our case, we a hybrid discursive field, because its structure posits two distinct understandings, the first related to the creation, specifically for the electronic arts, and the second related to the scientific knowledge as stated in more general enunciation: speeches in search of scientific certainty; questions about the very meaning of research and interpretation of speech.

In the case of our subject, the second module seems more appropriate since the goal is closer to the discourse on the relationship between art, science and general statement, discourse of the unfolding of the installation itself: scientific dissemination through interactive installations. In other words, it would deal with interrogation of scientific and epistemological junction, located here as a discursive element of enunciates subjacent to the enunciation.

Defined in this way, the playing field of discourse as a question about the search itself, namely, a methodological reflection that brings together aesthetic and science, we aim to define in the same way the field of semiotics that would fit within an analysis of this type of discourse: the interactive installation driven by the 'mean to say', your 'to make', [vouloir-dire, faire] the intention of disseminating scientific knowledge. Thus, every object as constructed by cultural signs (paradigms) in relation to a context by discursivity as defined by the enunciation, the underlying enunciates are so articulated (syntagmatic relation) that they define, so to speak, the emphasis employed in this relationship as explained below.

PARADIGM, SYNTAGMA AND SYMBOL

Resorting to the idea that the concept of time found in our installation can be articulated and addressed in accordance with certain relationships around the concepts of paradigm, syntagma and symbol. Consider, broadly, that paradigm is the set of signs that we hold to prepare a syntagmatic relation or an utterance: an established relationship within the paradigmatic set of signs. As an example of this process, proffer as a possible schematization of the sign 'time' as part of a set of singular and different times. The result of that provision in a speech, taken here in the broadest sense, is what will determine our choice among the possible forms of syntagmatic relation. This process can be extended to any set of signs, such as pictorial, sonic, filmic, or in the relationships established between them, such as in the case of films, performances in which there are a relationship between sound and image, among others.

Thus, if we consider the settings of the discourse in the form of modules, namely, the symbolic, the paradigmatic and syntagmatic, we see that the latter focuses on semiotics, i.e. the relationship between signs and their semiosis. This does not, of course, exclude the constituent elements or the base to be used for the construction of the sentence, or, a little more explicitly, the isolated signs, taken alone under their paradigmatic form. That said; between the paradigmatic element used for the installation and its unfolding narrative, we can observe the paradigm 'time' distributed in at least four contextual relationships: the temporality media, the literary, cinematic, and that primary concept of the work, the temporality from the point of view of physics. Such enunciates within the enunciation define the meaning [vouloir-dire] of the work and lead the interactor to interlace his own narrative that will be added to the initial proposal and the enunciatory can to produce their own speech.

METHODOLOGICAL STRATEGIES IN THE INSTALLATION A NEW TIME

One way to divide semiotic groups themselves to the installation which we analyzed, was to separate them by blocks and start our analysis by clipping of the proposals suggested by the installation and defined by the five devices already listed. With respect to the plane of the utterance, there is an important variable which we have to mention: Although the object we analyze seeks through sensorial perception an analysis of scientific concepts, their proposed goal is an artistic product, and thus on the one hand, travels the field of the domains (scientific, artistic or philosophical) for the field of reflection on art, and on the other hand, the reflection is proposed specifically about electronic art, and further a field delimited, one which comes to electronic art designed as an interactive installation, i.e., a scenario that is requested from the enunciate a physical and cultural participation that the existence and work may have meaning.

Another reflexive field is that of scientific concepts proposed by the course of the installation. The poetry of images, sound setting, the language of the texts of writers, poets and scientists, serves as an anchor and metaphor and thus these productions collaborate in driving the manipulation of the enunciatory. Not being able to predict a pattern like the enunciatory advertising campaigns (target models, such as youth, children, classes), a way was conceived to fill the void of knowledge (potential space) intended to be attained (update) in the form of monitors (discursive simulacra of scientific knowledge) that amplify the voice of poetic speech and scientific understanding that are proposed aimed at the installation.

As a result, the concepts of irreversibility, reversibility, relativity and simultaneity are treated by the specificity of their constructs and by the means that the interacting might handle.

PARTICIPATORY ART AS INNER CITY WORKSHOP: THE URBANREMIX SOUND PROJECT

Carl DiSalvo, Jason Freeman & Michael Nitsche

UrbanRemix is a collaborative and locative sound project designed to engage inner city communities with their neighborhoods through participation in a public art event. The project consists of mobile and web applications that allow participants to explore the acoustic identity of their communities as they record and remix sounds from their surroundings. This paper presents the concept and realization of the project in three different cities.

Urban Remix, 2010-11 Times Square project, map interface for sound mixing (left); Art on the Beltline project, Travis Thatcher live performance on location (right).

The UrbanRemix project builds on the idea of participatory art as a form of citizen involvement that engages people with their neighborhoods by encouraging citizens to re-discover their surroundings in a new way.

Participation has been discussed as a key quality of a range of contemporary artistic practices. As part of what Kester termed “dialogical art” it engages the audience, making their involvement an integral part of the artwork itself. “[A] dialogical aesthetic requires that we strive to acknowledge the specific identity of our interlocutors and conceive of them not simply as subjects on whose behalf we might act but as co-participants in the transformation of both self and society” (Kester 2004). Bourriaud differs in his approach to this kind of process-based art but comparable to Kester he stresses the “realm of human interaction and its social context, rather than the assertion of an independent and private symbolic space” (Bourriaud 1998). He identifies global urbanism as a driving motor as well as the stage on which the “growing urbanisation of the artistic experiment” (Bourriaud 1998) unfolds. UrbanRemix relates to this kind of participation and engages citizens in a new form of acoustic dialogue with their neighborhoods

and each other. It not only connects to the urban space thematically but also uses it as a source and stage for the artistic process itself. Sound recordings are gathered by local communities, shared via an open web site, and remixed online as well as in live performances staged in the neighborhoods where the sounds were recorded.

UrbanRemix is a platform that provides for participatory locative sound recording, mixing, and sharing. It consists of three key elements:

- a mobile application for capturing geo-tagged sounds
- an interactive online map for exploring and remixing sounds
- a range of outreach workshops and live performance events.

The UrbanRemix mobile application for Android and iOS allows participants to record sounds, take photos, tag them, review them, delete them, and upload them to a central server. Every sound recording is stored with its GPS coordinates, a timestamp, the ID of the recording person, and other customizable tags. Sound recordings are limited to 60 seconds and are uploaded as uncompressed audio files. Before they can use the application, participants first have to sign up on the UrbanRemix web site, where they agree to release their field recordings under a Creative Commons license. The application itself is available free of charge on the Android Market and the iTunes app store.

The web site (<http://urbanremix.gatech.edu/>) provides access to the uploaded media and allows participants to further tag the files, search them, and download them. The main interface to access the recordings, though, is an interactive map, built using the Google Web Toolkit. Recorded sounds are represented as markers on maps according to their GPS location. Users can filter the content of these maps for IDs, recording dates, or tags. Most importantly, they can click on the map itself to draw virtual paths through these locative recordings. Any path is then rendered as an audio soundscape mixing together the sounds closest to the path and changing their amplitude, panning, and filtering over time to reflect movement along the virtual path.

Participants are free to add more paths and can gradually build up an increasingly complex soundscape based on a multi-layered virtual traversal of the city. UrbanRemix allows further, more detailed sound manipulation as participants can loop and change rendering and mixing parameters in each path's settings. The result is an online mix based on the sounds recorded in the city and assembled with the help of spatial tracks crossing the city's map. Each mix can be saved, downloaded, and shared with other users. Finally, users can batch-download sounds to their DJ software and remix them locally on their computer.

The third element of UrbanRemix is a series of workshops and live performances. In practice, UrbanRemix comes to life in individual projects that center around communities and events at a certain place and time. Each project typically starts with workshops to inform groups in the neighborhood about UrbanRemix and encourage them to begin the collection of sounds and images. Discovering and selecting specific sounds for their own collection encourages participants to explore their neighborhood. It literally asks them to listen to their surroundings anew. Once the collection is complete, two forms of remixes are possible: online, using the web site; or offline, in the form of live performances. To prepare a public live performance, DJs download the collected sounds and perform live remixes using only the contributed content. All sound mixes, from DJs and other participants, can be shared and are found on the UrbanRemix site as well as other sound sharing sites.

A number of locative sound projects have addressed the use of locative media in urban neighborhoods. (see also (Freeman et al. TBP)). These include projects like Urban Tapestries (Proboscis 2004), [murmur], the Tactical Sound Garden Toolkit (Shepard 2007), Sonic City (Gaye, Maze, and Holmquist 2003), and the Silence of the Lands (Giaccardi, Eden, and Fischer 2006). UrbanRemix stands in the tradition of these projects and shares many comparable technologies and concepts such as maps, GPS, and locative

sounds. A key difference is, that UrbanRemix focuses throughout on a community aspect in the creation, mixing, and sharing of the evolving soundscapes. Sounds are gathered by local communities in their neighborhoods, shared and remixed online, but also presented back to participants in live performances delivered by professional DJs on location. The city becomes both a place for production as well as performance. UrbanRemix does not constitute an immediate intervention in the form of direct action but offers the chance to rediscover and reinterpret the spaces surrounding us.

Since summer 2010, we have conducted a number of projects with UrbanRemix that involved different audiences, cities, and neighborhoods. These include a project in the Tenderloin District in San Francisco, a project for the Atlanta Beltline project, and one at New York's Times Square. Various audiences have used the system, from High School students, to church community members, musicians, teachers, and media educators. Over time, UrbanRemix has proved to be flexible and portable and it has attracted some interest from artists and communities as an experimental platform for their own projects. In addition, UrbanRemix has been used as an educational tool in music classes during summer camps offered by the Atlanta Public Schools. The following paragraphs will focus on three projects in three different cities to discuss the project in more detail.

The Art on the Beltline project was part of a larger art program that addresses the multi-billion dollar redevelopment of the inner city of Atlanta. The art initiative is part of a 5-year plan developed by various communities and implemented in July 2006. As the development changes the city artists are invited to contribute projects that deal with the changing spaces and relate to what is marketed as "Atlanta's New Public Space." 270 artists contributed in 2010 and presented visual work, installations, and walks, as well as dining on the Beltline and musical performances on location.

As part of this program, UrbanRemix invited citizens to record sounds on the undeveloped locations before they will be reshaped by the upcoming development. The result is a form of acoustic virtual heritage that allows an audio-exploration of places whose character is bound to change rapidly in the near future. The final performance by DJ Travis Thatcher was held at a temporary stage on location at the Beltline on the border between the Old Fourth Ward neighborhood and Inman Park. The Old Fourth Ward is one of the oldest districts in Atlanta and has seen many changes in population and development. Today it houses the Martin Luther King Memorial site and is an example for gradual gentrification of inner city neighborhoods. Inman Park was Atlanta's first planned suburb and evolved into an expensive and largely historic neighborhood.

The biggest challenge during this project was to involve participants. Even though about 180 sounds were recorded, there were not many individual participants – possibly due to the way we announced the project as a "free for all" event instead of emphasizing more direct community involvement. The resulting sound collections might reflect a kind of virtual heritage or conservation of the location before the upcoming development, but they barely related to the socio-cultural conditions of the surrounding neighborhoods. This challenge of recruiting participants for the Beltline project informed our future work, making it clear that proactive solicitation of participation would be required. Still, even with limited participation, the outcome of this project is a collection of sounds that serves as a documentation of the acoustic identity of the space at one moment in the history of Atlanta.

A much closer collaboration with local communities was at the heart of the UrbanRemix project in San Francisco. The event was part of the City Centered Festival and hosted by the Glide Memorial Church. Originally founded in the 30s, the Glide Memorial Church developed into a thriving open community that actively supports often disenfranchised citizens of San Francisco. Since the 60s its program reaches out to a range of minorities in the city and offers housing, medical assistance, and educational programs. The surrounding Tenderloin district is a historic downtown area of San Francisco and a highly diverse neighborhood where inner city challenges such as crime and homelessness are found as well as historic buildings and thriving art communities.

Participants in the workshop included teen youth from the Glide arts program, instructors from that program, as well as interns and volunteers working at Glide for the summer. Over 170 sounds were recorded during the one-day workshop ranging from different voices in the neighborhood to detailed sounds, such as security keypads or traffic noise. During the project, a noticeable focus on recordings of voices emerged – as if the different citizens of the neighborhood were meant to find their way into the soundscape through their speech. Ken Ueno performed the public remix performance at a small gallery in the neighborhood. Because the project was part of a relatively short conference event, it faced a condensed schedule, which complicated the work of Ueno. He had only one day to familiarize himself with the recorded sounds for his live sound mix. While we managed to base the project better in the local community, the challenge remained to connect the process of remixing better to the chosen location. In large part this was due to the structure of the workshop, which emphasized sound collection over sound remixing. The lack of sound remixing after the project showed that we needed ongoing solicitation, even post-workshop events.

The UrbanRemix project at Times Square, New York was a collaboration with the Times Square Arts Alliance and combined the approaches tested before. Times Square is a renowned tourist attraction in New York, an extremely busy central hub that sees high traffic from both tourists and locals. The Times Square Arts Alliance regularly invites public art projects to Times Square. The goal is to let visitors encounter contemporary art and raise the profile of Times Square as a location. The invited projects include installations, projections, as well as live performances and are largely temporary pieces. UrbanRemix ran in April and May 2011, leaving the sound collection open for one month. The event was promoted online and through the Times Square Art Alliance on location to engage the audience. It also offered some prizes for the best online sound mix and the best sound recording to motivate participation. In addition, two workshops were held with students from the Jacqueline Onassis High School in immediate proximity to Times Square. A third workshop, co-organized by the New York media art collective Eyebeam, included local educators and media experts from museums, schools, and other institutions. Over 600 sounds were recorded and mixed by Thatcher and Damon Holzborn during a dual performance at the end of the project. They performed on a public outdoor stage in Times Square and in a second performance inside the visitor center nearby. The prize for the best online remix was won by a Brazilian artist, Osnilo Gesser Muller Junior, who had discovered the project online and had mixed his soundscape from his home in Brazil based on the recordings of the local participants. The prize for the best sound recording went to a local high school student. Thus, the project's outcome mirrors the double nature of Times Square as a lived neighborhood for its citizens, as well as a space of tourism and transit for a larger global audience.

No technical evaluation of user involvement has been conducted yet, but the informal feedback received in all three projects was largely positive. Participants often report new “finds” on their scavenger hunt for interesting sounds. This can be a discovery of something new in the all-too-familiar, like students discovering a fountain by “finding” the sound of water near Times Square in close proximity to their school, or it can be the documentation of a changing environment, as seen in the Art on the Beltline project.

Accordingly, participants showed clear signs of ownership of their contributed sounds throughout the projects. When they reviewed the sounds recorded for a specific project online, they often started with their own recordings, filtering out all other contributions on the web interface. At the same time, the live DJs were curious about the sound recording participants. Ueno stated after his performance in San Francisco that, “What I most wished to happen was to meet the people who collected the sounds and talk to them after my performance, which, unfortunately, didn't happen. I would have liked to have heard their impressions of what I did, and if they could recognize their contributions.” Different participants clearly engaged in the intended artistic musical dialogue “on” the location. This sense of shared ownership and personal connections was also visible in other UrbanRemix projects. In 2010 and 2011

UrbanRemix was used in music courses in summer camps with the Atlanta Public Schools. These camps allowed for a longer and more focused involvement. Students worked for approximately a week, recording and remixing sounds. Some students, however, not only created their own sound remixes but surprised us with their own dance routines based on their remix soundtrack. Reactions like these indicate that the engagement with their surroundings had clearly led to a new artistic dialogue.

Kester asked “How do we form collective or communal identities without scapegoating those who are excluded from them? Is it possible to develop a cross-cultural dialogue without sacrificing the unique identities of individual speakers?” (Kester 2005) Admittedly, not all boundaries for such a dialogue are eliminated in the case of UrbanRemix. Participation still depends on availability of relatively expensive smart phones, for example. Although we provide devices during the workshops, many other citizens remain excluded.

UrbanRemix succeeds in retaining the identity of individual participants within the sound collection and the evolving remixes. Participants not only pay special attention to their own sounds, but they also react whenever they identify “their” sound in somebody else’s remix. In that way, UrbanRemix provides an engaging platform for personal involvement with neighborhoods in a new sound-based dialogue.

Technically and conceptually UrbanRemix delivers a platform consisting of software, workshops, and on-line media. We constantly improve these core elements of the system, but to participants they appear as a “given” in any local project. Such a rigidity barely fits into the Dialogical Aesthetics outlined by Kester. It allows for a creative exploration of the surroundings, but only within the technical frame set by the underlying platform. On the one hand, this frees the participants to a playful involvement, on the other, it limits them to existent mechanics and restricts any alteration. For example, we do not teach how to change the code or hack the mobile application. In this regard, UrbanRemix constitutes a tool for artistic involvement that has an own rhetoric: what data is saved, who has access to the technology, what is the role of the administrator, how and where are projects publicized and conducted?

At the same time, each project is shaped by practical conditions depending on the participants but also on the conditions of the event, which include the scheduling of projects, availability of WiFi networks or electricity at the location. Even though they all used by-and-large the same underlying technical set up, each UrbanRemix project was unique. The system seems to encourage a ludic engagement that fosters a specific playful exploration of one’s neighborhood. This engagement should be seen as step toward Kester’s “cross-cultural dialogue” wherein performative and situated actions are integral part of the art piece.

Acknowledgements

We are thankful to all collaborators and partners in the individual projects. UrbanRemix is supported by a Google Research Award, Turner Broadcasting, the Intel Foundation, the Gvu Center at Georgia Tech, and the Georgia Tech Foundation. Additional project contributors include Stephen Garrett and Matt Gilbert. The project is available at <http://urbanremix.gatech.edu>.

BIG GAMES AND HIPSTERS: COOL CAPITAL IN PERVASIVE GAMING FESTIVALS

DAN DIXON

Pervasive and street gamers are compared and contrasted with the infamous subculture known as 'hipsters,' showing that although they are quite different social groups their aesthetics operate in similar ways. Specific attention is given to the emergent, socially relative nature of these aesthetics and the operation of 'cool' cultural capital. These findings are based on ethnographic field-work carried out in 2010 at the *Come Out and Play* festival.

Pervasive games are new forms of playful experience that have emerged from the intersection between ubiquitous computing technologies and computer gaming. They are played in the physical world, away from desktop computers and gaming consoles; expanding game space into lived reality. However, as an unstable, emergent or avant-garde field the labels are still in flux. Street gaming is a term that tends to be applied to an evolutionary subset of pervasive games that chart a trajectory away from obvious technology, but still sit in a milieu of childhood video gaming, smart phones, internet access and the ubiquity of the web. These games have followed a design evolution that has removed unnecessary technology and focused on appropriative, energetic and playful uses of the city.

This paper is intended to show that there is a close relationship between the cultural capital of those involved in street games and the aesthetic appreciation of the experience of these games. Using hipsters as a curiously interlinked subculture, I point out that there are similarities between the way the two groups manipulate culture and meaning.

One reason for this approach is that formalist, or functional, interpretation of the rules, models and patterns of street games does not set them apart as they are often similar to traditional, large-scale, playground or wide games. However there are subtle layers of meaning that do create clear distinctions for those with the necessary cultural capital and make these street games mean much more to the players than just their mechanics.

In the July of 2010, I carried out an ethnographic study of the street gaming festival *Come Out and Play* in Brooklyn, New York. This was part of a longer investigation into pervasive gaming festivals that also occur in London, Berlin and Bristol. Established in 2006, *Come Out and Play* is the longest running festival of its type in the world; an annual, weekend event, with game designers and players coming from across the world.

During *Come Out and Play*, I closely followed *Gentrification: The Game*, which would eventually win the prize for "best use of technology" at the festival, and filmed a team of players for the full two hours of the game. *Gentrification* was designed and run by Atmosphere Industries – a group from Toronto – and is loosely based around *Monopoly*. In the game, multiple teams of players, playing as besuited developers or local residents, are pitted against each other to fight for or against the forces of gentrification. Physically racing up and down streets to photograph themselves in front of properties – the mechanic to purchase locations – they would then go on to strategically build things such coffee shops or community

centers. There is an obvious irony in the game as the name suggests, especially as the designers specifically play the game in neighborhoods that are undergoing, or have undergone gentrification.

As these games are played in busy streets, in amongst everyday life and the players are performing unexpected actions, for example handing out flowers, singing, marching, making speeches, they are constantly asked what it is they are doing. For any street game, this appears to be a difficult question. After a number of attempts at describing to various local residents, one *Gentrification* player, whilst interacting with a man outside a US veterans centre hastily shortened his description to, "It's a hipster game."

Another, quite atypical, player was a local resident with a thick Brooklyn accent who had lived in the area all her life. She had brought her teenage son to play, as he liked acting and games, and ended up joining in this game herself. When I asked how playing this game made her feel, she described how all the other players were much younger and very different from herself; and finally, "It makes me feel like Williamsburg on a Saturday night." Williamsburg being recognized as the international locus of hipsterdom. [1] She said it made her feel highly uncomfortable.

Finally, as even one of the designers says, in a newspaper interview about the game, "We're interested in hipsters. That's it in a nutshell." [2]

Although the designer's quote appears to be flippant, between the three of them they have hit on something deeper about the relationship between who the players are and their enjoyment of the game. There is a deep and relevant parallel between hipsters and the players of street games.

Hipster – One who possesses tastes, social attitudes, and opinions deemed cool by the cool. The Hipster walks among the masses in daily life but is not a part of them and shuns or reduces to kitsch anything held dear by the mainstream. [3]

Defining the contemporary hipster is no easy feat for a subculture that prides itself on individuality and Internet-accelerated trends. The term itself is highly contested and in fact, for hipsters, being called a 'hipster' is something of an insult. [4] The term 'Hipster' first appeared as a reference to first black sub-cultural figures in the 1940s and then white sub-cultural figures in the 1950s. [5] Current hipsters emerged between 1999 and 2003, coming out of a post-punk, post-grunge neo-bohemia that is driven by a late-capitalist milieu of the experience economy. Hipster seems to emerge out of a thwarted tradition of DIY, alternative youth subcultures that have been integrated, humiliated or destroyed; leading to hipsters being anti-political and consumerist, ultimately deploying mockery and irony to communicate apathy and disgust around local and global issues. Paralleling Mailer's 'white negro hipster,' which fetishized 1950s blackness, the 21st century hipster, "fetishizes the violence, instinctiveness and rebelliousness of lower-middle-class suburbia and low-class country whites." [6] Some keywords that define this set of looks and interests are: "Trucker hats; undershirts called wifebeaters worn as outwear; the aesthetic of basement rec-room pornography; flash-lit Polaroids; fake wood paneling; Pabst Blue Ribbon; porno or pedophile moustaches; aviator glasses; Americana T-shirts for church socials, et cetera; tube socks; the late albums of Johnny Cash; and tattoos." [7] A final approach to definition is that the hipster culture appreciates and uses an aesthetic based on tensions, ironies and radical alterations between knowingness and naïveté, adulthood and childhood, pretentious complexity and foolishness.

Although both the book and event that are *What Was The Hipster* [8] devolve into denigration and hipster-hate it is one of the few serious attempts to analyze hipsters. Although the book is not especially

academic in itself, as it is made up of reportage and press articles, Bourdieu emerges as the only serious academic reference that any of the authors resorts to. Repeatedly in the book's various chapters and cuttings hipster tastes and style are denigrated, and as Bourdieu points out, tastes and style are not purely aesthetic, but socially and politically determined. [9] Hipster-hate is a classic example of what he calls 'symbolic violence,' the unconscious modes of domination within everyday social habits. This relation between aesthetics, class, education and cultural capital is seen to be crucial in analyzing hipsters and is also crucial in understanding the emergence of street and urban games.

Combined with cultural capital, Bourdieu's concept of 'habitus' is important in understanding both hipsters, and it is important in understanding why digital hipsters play pervasive games. There are parallels in their worlds that emerge in their different practices across different fields. Habitus is an unconscious set of predispositions, tendencies and inclinations, not so much rule bound, but playing within regularities. [10] This is down to similarities in the structures of their habitus and the way they both mobilize the logics of their cultural capital.

In her ethnography of Williamsburg hipsters Ingrid Tolstad describes how this subculture creates and manages the intangible quality of 'cool,' [11] and equates it to Bourdieu's concept of cultural capital. The ability to amass 'cool' capital results from the hipster's middle class habitus, level of education – usually university level – and high level of disposable income – from jobs in the media and creative industries. As Tolstad says, 'cool' has value, but it is very contextually dependent and is constantly redefined by the members of the subculture. Thus making it difficult for people outside the subculture to appear 'cool' or understand what makes someone or something 'cool.'

Although, as Greif pointed out, there are some common markers of hipsterdom, [12] from within the community the logic of 'cool' and the signs of membership are highly nuanced. This concept of 'cool' is aesthetically presented through retro-referencing and intertextuality in fashion and design. Raiding the late 20th century, the ideal hipster will select a clothing style from one period, tattoos from another and follow obscure bands, resurrecting music from the past: constructing a personal text to be interpreted by other hipsters, becoming both authentic and different at the same time. [13] The ability to both construct this individualized personal image and read the personal images of others is highly dependent on the individual's habitus and the level of cultural capital obtained through university level education. The hipster is a highly mobile and highly influential group of people, whose trajectory might well follow similar paths to the ones Bourdieu mapped for fashion houses in France. [14]

Our native Brooklyn player considered herself out of place; she felt surrounded by different people and equated that sense of alienation with the same feeling as visiting the hipster areas of New York. None of the players or designers of these games truly think of themselves as hipsters, or belong to that subculture. In fact raising the idea with some designers has provoked the same kind of hipster-hate as that which appears in *What Was the Hipster*. [15] However there are parallels between these two groups that go beyond these comments. These groups share many structural and aesthetic similarities that make pervasive, street and urban gamers a form of digital, or gamer, hipster. They are certainly not typical hipsters, but many phenomena are typically hipster.

The classic hipster employment is in specialist retail and service jobs, or in the advertising, media and content industries. [16] [17] Through my ethnography, I have found that players in street gaming festivals tend to work in digital media, web design, game design and generally the more creative end of the ICT industry. There are however subtle, regional differences in the make up of the main street and pervasive gaming festivals. These reflect the social networks of the organizers and designers as well as the

industry focus of the cities where they happen. For example, *Come Out and Play* in New York had a higher concentration of game designers and developers due to the large 'indie game' design community in and around the city which the organizers are heavily involved in. *Hide and Seek* in London is skewed towards the digital media industry, which would also appear to match up with the background of the organizers and the high concentration of digital media in London. *You Are Go* in Berlin seems to have drawn in many artists, again due to the organizers and the large population of art, especially media art in that city.

Players and designers of pervasive games share similar upbringings to hipsters. They are almost universally from middle class backgrounds and have achieved at least an undergraduate education. There is a surprisingly high level of post-graduate education amongst players of street games, and also a high level of academic involvement.

So there are similarities in upbringing and education across these two groups, but obvious differences in the types of common employment. These groups are obviously not the same and there is certainly a split between hipsters and street game players. However, even though there is local variation across the many different cities and countries there is a commonality of players of street games. Broadly speaking they all tend to be involved in what might be called the experience economy, the set of business that orchestrate memorable events for their customers; more specifically, those that are based on the creative application of digital technologies. Although there are exceptions to this rule, there is a high degree of commonality.

There is also one key aspect of street game players' upbringing that is very important. Again, almost universally, they all grew up playing video games and to a lesser extent tabletop, board and role-playing games. There is an embodied capital in their access to the stories, symbolism, gameplay and shared experience of video games, especially what are now known as retro-games. Most of the players at these festivals range from the mid 20s to the late 30s, and the games they would have grown up with are from the early 80s to the early 90s. These eras of childhood gaming seem to hold a particular fondness for the players that goes beyond memories of childhood.

It is not just that they grew up gaming, as many from these generations did. Although not as distinct a concept as 'cool' for hipsters, street gamers also tend to attempt the same kind of authenticity, honesty and depth in their relationship to some other forms of gaming. Most of the players I encountered have a strong engagement with some form of non-mainstream gaming, for example the *Civilisation* series, retro-gaming, *Minecraft*, or German board games. This creates high levels of very specific forms of embodied cultural capital: a form of capital that functionally fills a similar space to that which the 'cool' capital does for hipsters.

The games at *Come Out and Play* ran the gamut from playful punning, such as *CounterSquirt* – a water pistol game with victory mechanics from the computer game *CounterStrike* – to loving attempts at live-action recreations of classic arcade games, such as a game of *Asteroids*, with 16 neon-tube wearing individuals acting as chaotic, bouncing, break-apart asteroids. These games are packed full of both visual symbolism, but also functional symbolism through their borrowed rules, interactions and back-stories. These digital hipsters 'get' street, urban and pervasive games through their gaming histories, and in the same way that Bourdieu describes habitus, they have a feel for the game. This differentiates them from those who casually encounter these games.

Just as hipsters have a set of tastes that comes from interpreting the aesthetics that emerge from manipulating 'cool' capital, and retro-referentiality, so do street game players. They create, and are the only ones that can truly appreciate, street games that are based on a deep level of referencing and reverence of games in general, and especially those from their collective childhood. In the same way hipsters mix the themes of child and adult, naïveté and knowingness, street and pervasive games tend to also mix childhood with adulthood. Games from their collective childhood are referenced, reused and remixed. As one interviewee put it, they are "children's games with something extra," referring to them being suitably challenging, complex and involving for adults

Returning to the game of *Gentrification* there are multiple layers of symbolism and ironies at work that extend beyond the game itself. There are oppositions and inversions between the child and the adult. It can be seen as a simplified, scaled up, child's game of monopoly to explore the very adult concerns of gentrification. It is simple enough to be played by those in the know but complex enough to alienate the locals. There are levels of irony, in that these digital hipsters are playing at symbolic gentrification in gentrified neighborhoods, but instead only follows the resident and developers who are caught up in the eddies from previous waves of colonizing artists and hipsters, both regular and digital. This is a hipster game on many levels.

Street games can be games that work within these inversions and contradictions because the community of players understand them. Not all games work with this and can be simplistic, but the best of them play off these properties and their tight network of reference to bring out experiences that are more than just the mechanics of the games. As both Lefebvre [18] and Debord [19] point out, these types of playful activity can engage in powerful dialectics with space and society.

FACING PERCEPTUAL SHIFTS

MARGARET DOLINSKY

"Figuratively Speaking," a VR world, introduces Cubist figures from Dolinsky's paintings to a newfound dimensionality in virtuality where they establish both their personalities and the landscape. VR sets up a subversive confrontation by using a range of perceptual stimuli (visual, auditory, kinesthetic...) to exploit the artistic experience. Painting extends VR and the perceptual shift momentarily usurps reality.

Fig 2. *Figuratively Speaking*, © 2011 Margaret Dolinsky, VR World, Photo: Edward J. Dambik

Fig 3. *Figuratively Speaking*, © 2011 Margaret Dolinsky, gouache painting and 3D modeling are the inspiration for VR worlds

Introduction

The complexity of creating artwork for virtual reality theaters such as the CAVE Automatic Environment offers artists a multifarious palette that only begins with hardware and software. The aesthetics of an experience requires creating a plastic environment that ignites the imagination in order to inveigle the visitor and simultaneously engages the visitor. Virtual worlds immerse visitors with a range of perceptual stimuli (visual, auditory, kinesthetic...) that can be finessed through the artistic process. By setting up subversive confrontation between the visitors and the worlds in terms of such techniques as perspective, illusion and projections, a perceptual shift can occur that momentarily usurps ordinary reality. "Figuratively Speaking," a VR environment for the CAVE, is based on original watercolors of abstract figures whose faces, for the most part, are their bodies and concurrently compose the landscape. This deliberately confounds the environment to engage the visitor in a face-to-face dialogue with particularity and personality.

Facing perceptual shifts

There has been a historical tradition in art towards altering perception. My work in virtual environments employs dynamic imagery to heighten awareness, promoting what I call a "perceptual shift" for the visitor. A perceptual shift is the type of cognitive event of having experienced something extra-marginal, on the boundaries of normal awareness, outside of conditioned attenuation. [1] Perceptual shifts are often provoked by artwork such as *trompe l'oeil*, Cubism, Cornell boxes, labyrinth gardens, and Brecht's political theater. These devices for wonderment have a magical quality that requires a specific interaction unique to the particular device and its functions. Once the participant realizes his or her role within that interaction relationship, possibilities open for perceptual shifts and cognitive events. In my own work, I am not attempting to shape emotion in particular, but I do hope to shape perceptual possibilities within immersive environments.

Image making

I keep a sketchbook next to me at all times. It is especially critical in the morning. I reach for it before I am fully awake. I do not use an alarm clock, radio or other device. I avoid sounds and thoughts that define the day. I simply tell myself before I fall asleep what time I need to wake up. I sketch before I can articulate words, as if still captured in a dream state. It is during these hypnagogic moments that images form. Moreover, from the images, I recognize a sense of being. Rather than verbiage, motion becomes evocative, creating patterns of lines and shadows. The sketches come charging from the movements of my forearm that is channeling notations of memories and dreams that assemble themselves onto a surface. They are harbingers of narratives that temper and toughen consciousness and build gateways towards analogies. The sketchbooks are diaries, daily blogs in visual form.

Sketching impels me and inspires my paintings that inspire my virtual reality. At times, a sketch leaps forward, demanding further enhancement and calling to be fortified with color. I rarely understand the images before I paint them. I seem to know, without any calculated thought, which one needs attention. The process of applying color is seemingly ignited by an enticing song, as if sung by sirens. I execute the process of painting with mesmerizing fascination. I guide the brush to conspire with the surface. I counsel color onto a path where ultimately it is suspended from further voyage. The colors adhere to the plane, mixing with light, creating a surface, maintaining shape and decorum. As the culminations of my forces whip the brush's lashings into shape, the colors and shapes acquire integrity as entity. Color adds a dimensionality to the dreamt up image, provides a new parallel of existence, and extends my visual understanding of my process. Color establishes the robustness of the characters. It makes them whimsical, light-hearted yet at times, frightening.

The resultant image, a frozen structural moment finalized in time, becomes a world of contemplation that reorganizes itself as often as I look at it. The images begin to define a virtual environment and extend towards three dimensions. I create them anew in 3D computer modeling software. As the characters cultivate their relationships with one another, their prevailing forces energize to the real world and inculcate me with further ideas.

3D Virtual Worlds

The complexity of creating artwork for interactive stereoscopic cinema or virtual environments offers me a multifarious palette that only begins with hardware and software decisions. I consider my art images in terms of the connections they offer the visitor. The screens open to an infinite space that must be planned out as if it were real estate that is not necessarily grounded. The space offers multi-dimensional, gravity defying exploration with sensors triggering events. Illusion is presence. The 3D presence, completely illusory, is complex. It is visible through the light from the projectors coded in data. Each shape object model geographically maps the xyz Cartesian coordinate system and articulates a corresponding texture that maps the UVW components. They are co-located in the environment set with sensors for interaction. The hardware and software limitation mandates each facet of the artistic development with its own parameters and criterions. I must be vigilant. I am here for the experience dictated by my sketches.

Aesthetics of experience

The aesthetics of a real time animation experience ignites my imagination. I inveigle the visitor first through brightly colored and odd shapes depicted from my paintings. These shapes simultaneously engage the visitor, as they comprise the unusual characters to meet. Stepping into my real time interactive animation, the world is filled with the sights and sounds from my imagination. The environment navigates between my externalized imagery and my internalized thoughts. Small areas of the environment are confined to intensive interaction. The free navigation is halted by specific objects that manipulate sound. The juxtaposition of these events allows for free roaming thoughts with intermittent deliberations and activity.

Visual Perception

Virtual worlds are privileged by visual imagery. In "Figuratively Speaking," the original paintings dictate the aesthetic that guides the visitors through the experience. The paintings establish a 2D visual aesthetic that is extended to become a 3D space. The responsiveness of the visitors is encouraged through a range of perceptual stimuli including visual components, auditory design, and attention to kinesthetic movement. Rudolf Arnheim explains, "Visual perception is visual thinking... No thought processes seem to exist that cannot be found to operate, at least in principle, in perception."^[ii] The unique visual milieu energizes the experience. In order to navigate, one must identify the seemingly unusual imagery and make connections with it. In order to make sense of it and to make decisions, one suspends disbelief and interacts with art.

I design characters that look like heads. 3D allows them to move awkwardly, stare gracelessly and speak gawkily. They are simultaneously amusing and frightening. It allows me to establish an interactive relationship with a world I would otherwise only know in 2D (on paper and computer screens). I know the characters multi-dimensionally as a manifestation in 3D graphics or in rapid prototyping. I feel privileged to be able to extend the characters' conversation with me to others. I carefully place them to facilitate way-finding by creating visual choices or preferences for the visitor. The characters peak the visitors' interest and determine their next movements. I ignite attention through shape, size, color and brightness of the spatial configuration with the other objects that comprise the environment. This active selection and visual thinking creates a formula to design visual drama in the environment. Instead of drop down menus or folders with names on them, the objects are the way to navigating understanding.

The abstract imagery is reminiscent of the likes of Chagall, Klee and Picasso's cubism. The bright abstract shapes direct the visitor to explore particular paths. The fundamental elements of the imagery such as size, color, shape, and brightness can attract or detract the visitor to and from a route. These elements influence how the visitors' body moves along the path as well. At one point, all movement has to stop while at another it is slow in order to see what is unfolding nearby and in another, one cannot move fast enough to catch up with the moving objects, such as the boats in the water. My environmental design causes visitors to move to the side, lurch, and crouch and bend in order to anticipate a movement, face a situation or provoke events.

The visitors are also enveloped through the use of sound. The world is enhanced by sound that lifts visitors and carries them through the experience. The background audio is an ambient sound composition by Michael Drews and performed by the band, Big Robot.^[iii] The foreground sounds, heard when the events are triggered are composed by sound artist Rachel Weaver.^[iv] As visitors are listening, sound indicates where attention should be focused. Sound peaks thoughts and manipulates emotions. Sound provides context through acoustics and psychoacoustics. The malleability of the environment relies on the influence audio creates. Begault describes 3D sound systems as having four acoustic simulations: representation, replication, transmutation and creation.^[v] Creation is a completely unknown auditory

experience. This fourth simulation, creation, is what I find effective for my abstract environments to enliven the mood and engage the visitor in a theatrical art performance.

The design of audio, imagery and kinesthetics work in tandem to create a higher degree of temporal resolution and enhance the channel of communication between the visitors and the art.

Perceptual shifts

I construct pointers to perceptual shifts as the formal structure in my virtual worlds. I aim to capture those perceptual moments that are often lost because they are extra-marginal, outside the bounds of ordinary awareness. These moments are significant when they are initially recognized and lead the way towards integration of one with the surround. The environment must affect the visitor. Each visual element, auditory cue and kinesthetic activity represents a moment of recognition. These elements may act as a doorway, stairwell or tunnel that requires investigation. I establish the possibility for narrative by transforming the structure and architecture of the space into a series of visual and metaphorical guides for the participant. The environment is the navigational structure that ignites perceptual shifts and indicates the possibilities for interaction and, in turn, guides the overall experience.

The perceptual shift is established in terms of cognition, emotion and kinesthetics. The figures build a dynamic visual vocabulary. Combined with the awareness of time, the worlds are moving paintings. The visitors stand in the perceptual foundation of paintings that manifest experiential space. What is significant about creating virtual worlds is that it is the first redefinition of perspective since the Renaissance.^[vi] I extend this mathematical perspective with a perceptual shift in dynamics that allows visitors to face an unknown and synthesize to their present sense of knowing.

Figuratively Speaking

“Figuratively Speaking” is a virtual environment that establishes a ritualistic interaction of recognition, listening and attending. It is inspired from a series of hynagogic paintings. The paintings feature portraits that are simultaneously faces and figurative characters. The composition of the painting is in a six-panel grid formation. The painting allows the eyes to navigate the images in a sequential fashion, much like abstract comics. The virtual environment allows the body to navigate in a nonlinear fashion, similar to a stream of consciousness movement. The portraits provides affordances for the VR environment to establish methods for way finding.^[vii] The faces are portraits, figures and landscape elements.

Some of the perceptual context of this work looks at the research of Reber et al who suggest that aesthetic experience is a function the perceiver's processing dynamics. "The more fluently the perceiver can process an object, the more positive is his or her aesthetic response... Finally, the impact of fluency is moderated by expectation and attribution."^[viii] The experience of searching is governed by the aesthetics and the emotional tones of the faces/figures. Together, context and conceptualism, evokes exploration, recognition and discovery. The face is a metaphor for identity. The face represents a kind of knowing the self, determining where one is in relation to the other. The face also represents a kind of knowing of the other, determining where one is in relation to place and path. The face is also body and parts of the body makes up the landscape. Therefore, the face is also the grounding force. The visitor is immersed in a subversive confrontation with face and identification. This deliberately confounds the environment to engage the visitor in a face-to-face dialogue with particularity and personality. While navigating, the visitor constructs a narrative and the visual conversation moves between the artist, the visitor, and the artwork.^[ix]

Conclusion

My virtual environments seek to create perceptual shifts by setting up subversive confrontations between the visitors and the world. Visual design techniques for virtual environments such as perspective, illusion and projections are only the beginning of creating experience. My worlds are inspired by abstract drawings that are painted and reconfigured in 3D. In "Figuratively Speaking" the adventure is established through the use of abstract portraiture. The visitor must reckon the moment by coming face to face with her reality.

The forces from the paintings will inseminate a virtual world where the objective is that over time and by navigating through space, visitors produce their own momentary narratives, similar to my recognitions of my own perceptual shifts. The visitor navigates, explores and contemplates the environment, as if they too can recognize an extra-marginal moment in time.

"Figuratively Speaking" is an artwork that realizes 2D painting as the foundation for a virtual environment aesthetic. The vibrant colors and unique forms energy the environment and illustrate the dynamic playfulness of relationships between faces and characters, real and virtual. The change in scale and repetition of forms encourage exploration of the figures as both characters and as landscape. Beyond mere viewing of a frozen image, visitors can move and explore towards an aesthetic experience.

ART AND LIFE: BIOCYBRID SYSTEMS AND THE REENGINEERING OF REALITY

Diana Domingues, Adson Ferreira da Rocha & Cristiano Jacques Miosso

Ontological levels of creative reality and the reengineering of life provided by the BWAS– biocybrid wearable affective systems – configure the expanded sensorium and the health measures against the infirmity of landscapes, in biodiversity. Art and Technoscience combine developments in biomedical engineering in physiology and synaesthesia into the drama of life and the embodiments in Brazilian cultural rituals, urban space, domotics and ecology.

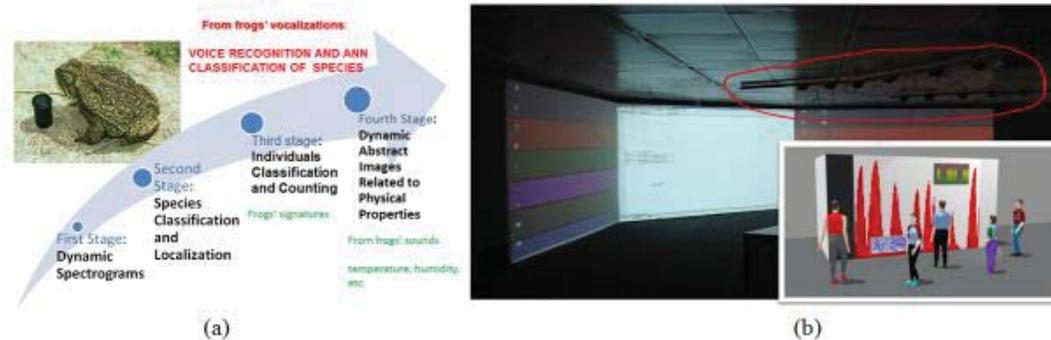

Figure 1. (a) The four stages in the development of the system for the classification of frogs' vocalizations. (b) A large screen for the manipulation of visual and sonic information.

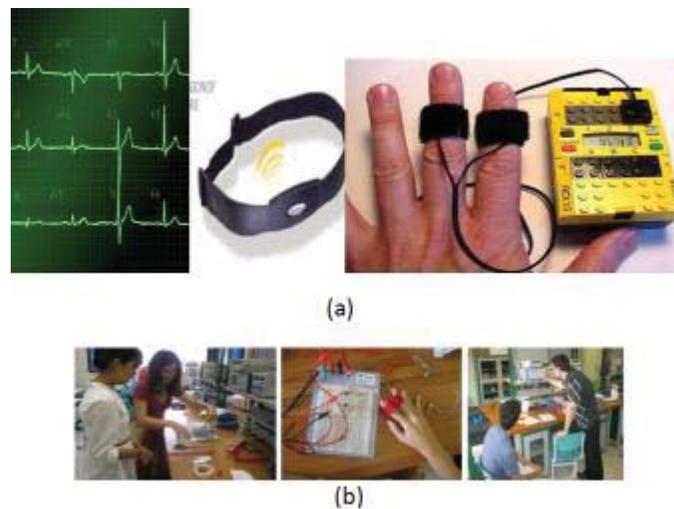

Figure 2. (a) Circuit sensors for the biocybrid condition. (b) Laboratory of instrumentation, where we develop the biosensor circuits. BWAS mobile wireless using non-invasive sensors for the body capture electrophysiological signals - galvanic skin resistance, breathing rates and heartbeats, which are treated and transmitted.

1. Introduction - Biocybrid systems and the drama of life

Challenges of the world, increasingly technologically dependent, are faced by our biocybrid circuits of sensors, blurring the limits of the natural worlds and the engineered reality. Creative technological levels regarding body, landscape and the urban life of our biocybrid systems are provoking the end of the “nature itself” and the emergence and “the future engineered reality”. The Group of researchers at UnB Gama in the Biomedical Engineering Graduate Program and in the Laboratory of Research in Art and TechnoSciences – LART develops biocybrid systems for human existence in the continuum and symbiotic zone between body and flesh - cyberspace and data - and the hybrid properties of physical world. That continuum generates a biocybrid zone (Bio+cyber+hybrid). [1] We add biofeedback circuits of sensors, therefore, bio signals to the cybrid condition, pointed out by Anders in 1998, [2] and we investigate complex enactive systems of creative technologies which reinforce the *natural* history of artifacts, with cyber technologies and transparent interfaces ubiquitously mixed to phenomena of ecoscosmos life.

Biocybrid condition is the co-existence in the physical and cyber worlds connected by enactive interfaces allowing biosignals communication and affordances in the “narratives of life”. Anthropologically, we propose the affective wearable condition, resembling Picard’s investigation on affective computing. [3] We reinforce the liveness condition and the reengineering of our sense to be alive in every act through our biological signals. This approach is not new; we only gain creative levels for the understanding of our relationship human/environment in the remote theory of enactment, as in Aristotle’s *Poetics*. [5] Enactive interfaces embodiments reinvent the drama of life by Aristotle and life is a complex act of being enacted to the environment by biosensors.

1.1. THE AFFECTIVE AESTHETICS

The body as part of an interactive system evokes the expansion of the aesthetic dimension in conceptual and body art with responses generated in symbiotic zones with programs within “hermeneutic operations,” dealing with biophysical laws, when code and facts are experienced in the intensity of the senses and the ability of data laws built into the system. In the field of *endophysics*, [4] Rössler’s interfaciology points out what the Performative Science is.

Reaffirming the origins of the discipline *Aesthetica*, postulated by the German philosopher *Baungartner* in 1750, we propose embedded systems for synaesthetic experiences of biosynthetic bodies and the ability to perceive the world with the five bodily senses. Physiology and synaesthesia are the main topics for our microcircuits.

Biosynthetic interfaces integrating biocybrid systems are no longer machines, but complex systems, surpassing the human condition and limits of the mechanistic paradigm. We must delete this old classification and consider human/animals/environment as a complex, living organism. In 1997, we had already discussed, in the *Flesh Factor* list of Arts Electronica Memesis Symposia, [5] some theoretical aspects related to this development.

In the 1990s we started to postulate the interest of sciences on the human factor of technologies, increasingly growing to the spiritualism of their theoretical approach. We now propose the biosynthetic interfaces expanded to *biocybrid* systems and ecstasy. But in the earlier form, we had already started postulating the trance. Our projects described in Section 3 analyze rituals in the passage from trance to ecstasy. We consider the “sentences” of the body movements, called *parakinemas*, which come to existence due to stimuli, whose basic components appear also in the Brazilian culture’s rituals and myths.

In a general way, the point is to consider the myths and old ontologies close to the biocybrid systems, the reengineering of sensorium and the reengineering of nature.

2. Reengineering Nature – Biodiversity, Infirmary and Affectivity

Assuming the role pointed out by Louis Bec, we are engaged extremophiles, [7] working in the direction of a cultural and anthropological paradigm, and concerned with the planet’s health. In the same way of ontological levels of creative reality and mutual influences with environment information related to the James Gibson’s ecological perception theory (1986), [6] we investigate the ecosystem in its dynamical relations between human, animal, plants and landscapes.

The urgent attention to life in our country’s huge territory calls for the extremophile creative attitude, facing the effects of an endemic infection of tropical climates as well as the challenges of the biomes in the Amazon Forest. We consider the infirmity of the territory and the human invasion and destruction of the ecosystem self-organizing defense.

We will describe two of the types of research we conduct: *Sapio – biodiversity, infirmity and affective geography* (Dengue infirmity and health care) and *Frogs’ signatures: Pantanal Bioma in Amazonia Forest* (preservation of ecosystem and biological community).

2.1. SAPIO: BIODIVERSITY, INFIRMITY AND AFFECTIVE ECOSYSTEM

The System for the Acquisition and Processing of *Ovitrampas* Images (SAPIO) develops an automated tool for monitoring, fighting, and preventing *dengue* in creative extremophile actions regarding a human/environment/net, natural/artificial, remote/local and rural/urban structure in mutual contamination. Dengue ecological information analogous to the principle of the ouroboros mythic serpent, and self-regenerating emergent narratives about health care and dengue. Interfaces localize the *ovitrampas*,

special traps that collect the mosquito's eggs and reveal infestation tendencies allowing the prompt definition of control actions. The SAPIO project is aimed at obtaining and analyzing ovitrampas images, in order to automatically count the deposited eggs and to disseminate the collected information through the World Wide Web.

2.2. AFFECTIVE GEOGRAPHIES: INFIRMITY OF THE LANDSCAPES AND NEW ABSTRACTIONISM

Our Biocybrid cultural platform mixes people's life and behaviors to the natural physical environment, by using data collected mainly data from geography (GPS, Google Maps) and SIG regarding the infirmity of the landscapes. The processes are fundamentally different from photography and television used in Brazil, using tools such as data visualization, scientific methods of signal processing, web semantic and visualization of social nets, augmented reality and mobile devices using APIs for Google maps, Google earth, SMS, Blogs and Wiki Maps. Learning and teaching about the epidemic mixes experiences in the physical world and in the digital environment, with collaborations and reciprocity. The co-location in the virtual and physical environments makes virtual worlds reengineering physical world. They share the responsibility and affection to the landscape, meanwhile the Art History, in the domain of the new abstractionism is enhanced by signals processing, data visualization, satellites eyes, computer vision, and other synthetic systems. The CyberAdams and health care reengineer reality.

2.3. FROGS' SIGNATURES IN THE PANTANAL BIOME

In another line of research, we investigate the frogs' populations in the *Brazilian Pantanal* area, and explore the richness of information in the frogs' vocalizations. This sonic landscapes theme is the research focus of the PhD student André de Oliveira, enhanced by our investigations on data visualization and signal processing. The data visualization and sonification system in voice recognition and intelligent methods to analyze the properties extracted from the frogs in Pantanal Bioma are summarized in Figure 1 (a). The automatic system will provide to the biologists the classification of species and the number of frogs living in that remote bioma which will replace the old and analogic ones.

In developing the biocybrid system and the simulation of the human proximity using wearable art and biosensors to act and actualize, by immersive synthetic biofeedback interfaces the data landscape – large data screen or cave, exemplified in Figure 1 (b) – and the manipulation of visual and sonic information, in dialogues with the distant *Pantanal* Biome. Metaphorically, we propose the frogs' signatures and the human behavior dealing with laws and phenomena of the cosmos, by influencing life of nature inside the world as a living organism exchanging electrical potentials, heats, sounds and vibrations and the sense of presence being advanced by the technological apparatus and affective biofeedback for the responsibility of humans and a healthier territory.

3. Reengineering Senses – Biocybrid Systems and Expanded Sensorium

We develop microcircuits with sensors for the creative levels of performance and *coinaesthesia* – all the sense, to reaffirm the potential of affective aesthetics. Manufactured synthetic senses for enactions and synaesthesia [9] as filters for translating the intertwining of the body with the technological environment configure that perception as a laboratory phenomenon, as Krueger described in his "Redefining

Human". Microcircuits of wearable biosensors referenced in Maturana and Varela consider the interactions with the environment as sources of percepts, rather than mere representations and the body is involved in a neuropsychophysiological way, with mutual interactions with the whole environment. [8] Physiology and synaesthesia are the two topics for biofeedback

3.1. SYNTHETIC SENSORS AND THE OUROBORUS PERCEPTION: THE SEAMLESS AND ENDLESS AFFECTIVITY

The endless ouroboric principle of life, by Domingues, [2] with the mythic serpent eating its own tail and self-regenerating life, is expanded in wearable affective biocybrid systems. We invest in technological innovation regarding the miniaturization of hardware systems that have enabled the development of network sensor nodes, for interconnected wireless networks and assistive medical applications. According to Rocha, [11] these sensors have the ability to detect or measure some phenomenon of nature, processing and transmitting data or information to other sensors. In our artwork the circuit is built in an intelligent network inserted in a set of accessories, which coupled to bodies configure the Biocybrid Wearable Art System (BWAS), exemplified in Figure 2(a).

3.2. THE PERIPHERAL PERCEPTION: EXTRUSION OF EYES AND COUPLED VISION

What is vision now?

The recent anthropological biocybrid mobile condition amplifies the phenomenology of "being here" (Barthes), altered by the use of mobile cameras of cell phones, and the locative and geographic interfaces. We perceive with three eyes, and no more only coupled to the mechanical eye of the photographic camera. In January 2011, we discussed, in the SPIE conference, *virtual reality reengineering reality* session [1] and the inclusion of synthetic objects in physical concrete spaces by mixed and augmented reality and computer vision. The system reaffirms the post biological extrusion of human vision, by the act of seeing shared with the satellite eye in the sky and the handled eye of the mobile device, expanding the human perception. Tags in AR placed in a GPS (Global Positioning System) and the possibility of geodesic coordinates create a co-located event for human body. The neuropsychophysiological perception expanded by data signals processing, geotags and computer vision allows interventions in urban life, using mobile augmented reality (MAR). The ecological geolocated art event *Borges Fantastic Creatures in Buenos Aires' streets* insert Synthetic creatures in the city.). The earlier *14 Bis* biocybrid system, celebrated Brasilia's 50th birthday, in a public event where the plane, invented by the pioneer Santos Dumont invaded the sky. In the Domotics field, we use the BWAS in connection to a specific environment (home, office, hospital or other), and the relations between the inhabitants and the space, as well inhabitants, patients and doctors etc.. Regarding biomedical applications, the relationship of distance between individuals is a relevant factor in the recovery of some diseases. The certain distance from other people or objects, and the invisible bubble of space which is the "territory" is one of the major dimensions of modern society are the approaches to LART PhD student Tiago Franklin Lucena in his Project *Cidadepathia*.

3.3. TRANSPHYSIOLOGY OF PASSIONS: EXTREMITIES OF THE BIOCYBRID CONDITION AND RITUALS: FROM TRANCE TO ECSTASY

In the same attitude of creative extremophiles, we focus on the expanded sensorium in data visualization and biosignals, reconnecting the body and its physiology to the rituals. The concept and operational

principles: 1) the body's schemas based on Rudolf Laban's corporeal graphics or Labanotations; and (2) kinesthesia, always perceiving and processing data of human physiology and affective levels in scientific analyses of electric potentials and biofeedback using the BWAS. The kinesthetic Labanotation schema enhanced by the data visualization methods, in sensorial properties of synaesthetic biofeedback provide us the kinetography mixing the Kinemas, as a language of movement in a transphysiological dimension. Aspects of motion, electricity, graphic design, in data visualization and data sonification: body movements, translating graphics, gestures, postures, fragmentation, reinstatements, dynamics, internal-external connections and motor schemes, dealing with gestures, rhythms, not only at each stage of the movement, but also in consideration of what affects you, the environment and the coupled interior and affection in the flows of life with affective wearable sensors. The resulting concept fundamentals the transphysiology of the Ecstasy is rooted in the concept of the Transphysiology of Passions and Trance, proposed by the supervisor of this research, Diana Domingues and discussed in the post doctoral research by Donato Cida / CNPq. The body's electrical potentials rising from ecstasy in Brazilian rituals such as the carnival and Afro-Brazilian religions as Candomblé and the shamanic trance differs of the ecstasy states. In the ceremonies that involve embodiments in deep levels of unconsciousness, the ecstasy and their sensations, emotions and thoughts, attempt the condition of transcendence, embedded in mediunic state. The internal excitations of the nerves and sensorial apparatus caused by the impression of the senses are translated in its transphysiology, where the sensorial and affective presence is measured. Laban's paradigm postulate that human movements are always composed of the same elements, whether in art, at work, rituals than in everyday life. Consequently, we search for a method with emphasis on the psychological and physiological aspects that lead human beings and electrical biopotential of a body, which in their combination produce states, qualities, actions and parallel motion feature psychic actions present in our actions – recognition in the form of rhythms and structures – the *poiesis* of a bio-cyber body.

ART AND THE EMERGENT IMAGINATION IN AVATAR-MEDIATED ONLINE SPACE

DENISE DOYLE

This paper presents a framework for what is termed 'the emergent imagination' (developed through a recent PhD thesis) that arises out of the transitional spaces created in avatar-mediated online space; and argues that the conditions for 'the emergent imagination' are best generated where the experience of space is heterogeneous and where the plasticity of time-space relationships is articulated.

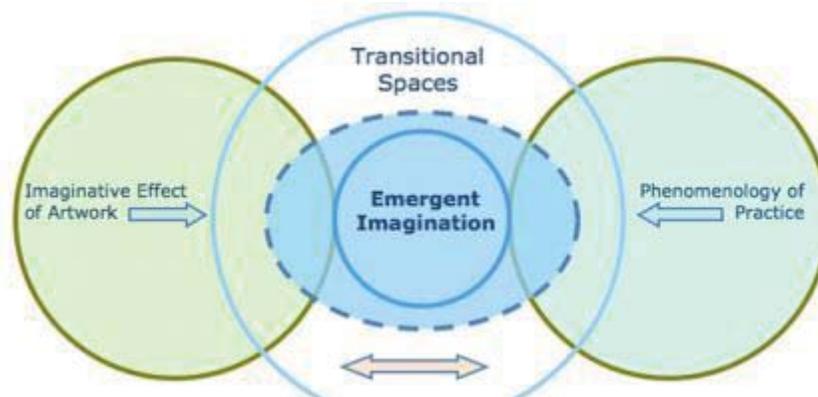

Figure 2. *A framework for the Emergent Imagination* (2010) © Denise Doyle

Far from the immensities of sea and land [...] isn't imagination alone able to enlarge indefinitely the images of immensity? [1]

Introduction

This paper presents a framework for what is termed 'the emergent imagination' (developed through a recent PhD thesis) that arises out of the transitional spaces created in avatar-mediated online space, and it examines how contemporary notions of the virtual have changed our framing of the imaginary. According to Edward Casey, "imagination (in Western thought) is not securely situated in regard to such decidedly different acts as sensory perception and conceptual thinking." [2] Perhaps this is because, "imagining is easy enough to enact as experience, but it is extremely difficult to capture in midair for the purposes of scrutiny and examination." [3] This paper considers the importance of investigating imaginative experience in relation to the process of artistic creativity and practice and discusses the ways in which the 'virtuality' of avatar-mediated online space impacts on the 'reading' of the artworks created in the space itself. Referring to the heterogeneities of space explored in virtual worlds, the paper argues that whilst the virtual remains connected to time, the imagination becomes connected to space, and through this a new set of time-space relationships in virtual space can be articulated.

Avatar-Mediated Online Space

Since its inception eight years ago artists have been exploring the virtual space of *Second Life* where the act of creating is already mediated through technology. The *Critical Works in SL* exhibitions were presented during 2008 and 2009 on Kriti Island, which acted as a laboratory space for ongoing artistic and imaginative practice research in *Second Life*. Central to the development of the space was the community of experimental artist practitioners who relied on a particular form of collaborative co-operation. The research began with a grass roots development from connections made within the space itself. As an artist-researcher, the main strategy was to create a presence on the platform and invite others to participate. Kriti was also a space for the presentation of the process of thinking in relationship to the key themes of the exhibitions, that of the imaginative potential of the space and the subsequent exploration of the relationship between physical and the virtual spaces. Following the realization of the exhibitions, interviews were conducted with six of the participating artists and analyzed for the artist's insight in the context of creating immersive and interactive experiences in the *Second Life* space. The accepted format of the artist's interview traditionally explores the tacit knowledge base of the artist's experience and draws out any impact on the artistic process. However, a further method was used for the analysis that exposed a previously unacknowledged layer of experience for evaluation, that of the phenomenological method of Imaginative Variation. In this approach, the interviews were analyzed to uncover the essence and meaning of an experience, in this case 'the artist's experience of being a creative practitioner in virtual space.'

What criteria can be used to examine and make sense of the array of artworks produced in *Second Life*, and how can the practice undertaken there in the lifetime of the platform be reviewed in the context of contemporary art or New Media practice? What modalities of art are being explored within the space? The concerns appear varied and multi-layered. There is the continuation of the contemporary arts discourse in the *Second Life* space, there is the anarchy of social engagement and participation, and there is the recreation of painted virtual spaces where the issue is either their ability to come to life, or the ability to do the unimaginable, to walk around and be immersed in pictorial space. This play of the

imagination incorporates the re-enactment of art and performance events. All of these movements and actions have come about on the *Second Life* platform during the last eight years.

Analyzing the Kritical Artworks

In his 2009 article, 'The Translation of Art in Virtual Worlds,' Patrick Lichty outlines a number of interesting questions with respect to artists working between the virtual, and what he terms the 'tangible.' He presents four modalities of art in which the modality "refers to the location and vector direction of the work's relation between worlds." [4] He suggests there are four modalities of art currently being produced in virtual worlds: the Transmediated, the Evergent, the Cybrid and the Client/Browser work. He explains:

This epistemological 'movement' within and between worlds has four basic structures; work that is essentially traditional physical art translated to the virtual, 'evergent' work that is physically realized from virtual origins, the virtual itself, designed entirely for the client/browser experience, and 'cybrids' that exist concurrently between various modalities. [5]

The transmediator, according to Lichty, "tries to align the tangible and the virtual," [6] and this movement is illustrated by the vector direction of the transmediated work from the physical world to the virtual world. According to Lichty, an example of work that is within this category is Marina Abramovic's *Seven Easy Pieces* (2005). A second modality of art are those built for the client/browser experience. The semiotics of these two modalities, the transmediated and the client/browser, are, as suggested by Lichty, "a straightforward affair." [7] The Cybrids, according to Lichty, "are less concerned with continuity, but are interested in the differences and distinctions between worlds and scales." [8] Both the Cybrid and the Evergent works demonstrate a "movement from virtual to tangible, which includes consideration of works existing in simultaneous physical and virtual components, [and] present more complex models." [9] This complex play within and between worlds, in particular "the enigmatic liminal works that live between worlds," [10] those spaces that are potent for the imagination, already demonstrate an array of creative potential in the *Second Life* space. My own project entitled the *Meta-Dreamer* (2009) could be considered to be an evergent work based on Lichty's proposition. Working with digital materialization expert Turlif Vilbrandt, [11] data was extracted from *Second Life* to create a digitally materialized object of my avatar, *Wanderingfictions Story*. By experimenting with digital processes and the type of material used, attempts were made to represent jade and clouded glass, amongst other textures. The end result can be seen in Fig. 1: the qualities of the figure are cloud-like and ethereal as though she (the meta-dreamer) is 'almost there.' [12]

The Emergence of Transitional Spaces

The vectors of movement of the four modalities of art described by Lichty can be considered to denote the directions and creations of meaning between the physical or tangible world, and the virtual world, and movements within and between virtual spaces themselves. These vectors of meaning are, in the Transmediated artwork, from the physical world to the virtual; and the vector movement of the Evergent artwork, is from the virtual to the physical or the tangible. A third vector can be placed within the virtual world space and denotes a circular and self-referential movement within virtual and imagined worlds themselves. A fourth series of vectors move between the spaces denoted as Cybrid spaces where connections and augmentations of artworks are multiplied and duplicated. However, these vector movements could also be considered to be that of the 'movements of the imagination' itself. If the

modalities of art and creation of imaginative effects are compared it appears that spaces in transition provide the movement where meaning is created. Through the research it was found that the imaginative effects created in the artworks and presented in the virtual world of *Second Life* arise out of four categories of transitional space: the surreal, the fictional/poetic, the emergent, and the spatio-temporal.

An outcome of the research was the development of a new framework for the imagination (presented in diagrammatic form in Fig. 2). 'The emergent imagination' can be seen to emerge from both the heterogeneities of space created in the imaginative effects of the artworks and in the artist's act of creating through a phenomenology of practice. The transitional spaces are at the centre of the framework itself and out of which 'the emergent imagination' comes into view. The conditions for the appearance of 'the emergent imagination' are seen both in the act of creation and in the outcome of the creative act itself. In the analysis of the imaginative effects of the artworks it was noted how the transitional spaces created suggest the presentation of space as a field of becoming. The heterogeneity of space created has at its base the multi-faceted experience of space and its changing relationship to time. Additionally, the phenomenological account of the artist's experience of creative practice in the *Second Life* space suggests a varied experience of embodiment and imaginative experience. [13] The wide-ranging accounts of the artists indicated the extent to which time, space, and time-space relationships were central to this experience. In the creation of the framework for 'the emergent imagination,' the experience of embodiment and the associated imagination of the senses may explain the visceral and material responses to the phenomenological experience in virtual space.

Time-Spaces of the Emergent Imagination

It is pertinent to consider Casey's description of imaginal space, imaginal time and the imaginal margin (following his first-person phenomenological study of the imagination) with respect to the framework for 'the emergent imagination.' In describing his experience of imaginal time, Casey writes that in the felt presence, "not only was there no single temporal matrix extending throughout [...] in each instance there was present a vague positioning of given items of content within a time span." [14] In describing imaginal space Casey writes, "in spite of their diverse and often truncated character, these varieties of spatial expanse were nonetheless intrinsic elements of the imagined content [...] for all such items of specific content are invariably presented as localized, if not strictly located, within imaginal space." [15] Finally, with respect to Casey's imaginal margin, it is described as, "the fading fringe found at the outer limit of specific imagined content [...] being almost entirely featureless, it cannot be given any definite location." [16] Echoes of the imaginal margin are found in the explanation artist Taey lohe provides of her experience of allowing her mind to drift in the *Second Life* space, not knowing if she sees a half wolf or a half dog at the edges of the world as though she is describing the space of a dream or reverie. [17] With respect to Casey's study, there is no real sense of the positioning of an imaginative experience in time and this is also the same for space. There is no real geography of the imagination in a physical, locatable, Cartesian sense and this is reflected in the heterogeneities of space experienced in avatar-mediated online spaces. A field (rather than a geography) of the imagination may be a more suitable account of the experience.

Doreen Massey, in an essay responding to the work of artist Olafur Eliasson, attempts to illustrate a set of relationships between time and space by using a narrative account of a journey between Manchester and Liverpool. In the process of traveling she suggests, "if movement is reality itself then what we think

of as space is a cut through all those trajectories; a simultaneity of unfinished stories.” [18] Furthermore:

Space has its times. To open up space to this kind of imagination means thinking about time and space together. You can't hold places and things still. What you *can* do is meet up with them [...] 'Here,' in that sense is not a place on a map. It is that intersection of trajectories. [original emphasis] [19]

If each space has a particular time, as Massey implies, then the transitional spaces that have been identified in avatar-mediated online spaces may also have a particular time attached to them. Not only, then, are there heterogeneities of space but also different sets of time-spaces that can also be located in the *Second Life* experience. The time-spaces of 'the emergent imagination' may also share their qualities with mythic time. Of mythic stories, Jay Griffiths writes:

[They] talk time out of mind, charm time and trick time, clogging it or stretching it: fables make time fabulously paradoxical, a stubborn blot on the face of clock-time but true to the time of the psyche, where past present and future are kaleidoscoped. [20]

Even Gaston Bachelard writes in the *Dialectics of Duration* of different levels of temporal experience:

As soon as we had acquired through mediation some skill in emptying lived time of all its excess and ordering the different levels of temporal phenomena into a series [we] saw that between this passing of things and the abstract passing of time there is no synchronism. [21]

All of these expressions suggest a plasticity to time as a lived experience, but also to the specificities of time-space relationships.

Conclusion

Sean Cubitt suggests that in online arts it is in the combination of a “spatialisation of time” and “the re-making of actual-virtual relations’ that the peculiar ephemerality of online arts makes new sense.” [22] The very notion that Cubitt expresses here is the very set of relationships discovered to be at the centre of a framework for ‘the emergent imagination.’ The analysis of the imaginative effects of the artworks presented in the two virtual (and physical) gallery exhibitions of the *Kritical Works in SL* project demonstrates a mode of artistic exploitation of the particular combination of user-generated and avatar-mediated spaces. These virtual, sometimes liminal and always transitional, spaces that emerge from the artworks are complex and multi-layered. A further analysis of a phenomenology of the practices of artists in avatar-mediated online spaces reveals that the imagination is experienced as embodied. A materiality to space is identified through an imagination of the senses that responds to the presence of the (imagined) body of the avatar. Here, the conditions for ‘the emergent imagination’ are best generated in avatar-mediated online spaces, where the experience of space is heterogeneous and where the plasticity of time-space relationships can be articulated.

This paper explored some of the philosophical implications of virtual worlds, through an examination of the concept of the imagination as that concept is seen in light of the pervasiveness of the virtual in our everyday lives. The thesis presented here posits that it is precisely in the generation of ‘the emergent imagination’ in avatar-mediated online spaces that we can best enrich our ‘real world’ lives, by applying

some of the emergent experience of the plasticity of time-space relationships and the heterogeneity of space itself to our lives in the world around us.

NOSTALGIA TI FREGA

Carla Drago

Nostalgia Ti Frega is a photographic exploration of memory, identity and place that focuses on the emigrant community of a Sicilian village destroyed by an earthquake 40 years ago. This paper outlines the key influences across disciplines that have shaped the creative framework of the project.

Nostalgia Ti Frega, 2011, Carla Drago, photographic media, Copyright Carla Drago.

THE PROJECT

Nostalgia Ti Frega is a photographic project being completed as part of a Doctorate of Creative Arts at the University of Technology, Sydney. An exploration of memory, identity and place, the project focuses on the emigrant community of my father's Sicilian village of Salaparuta, destroyed by an earthquake 40 years ago. Aiming to capture a sense of the virtual space the village now inhabits, the project will consist of both digital and analog photographic objects: a limited edition set of photographs, printed on fine art paper, and presented in handcrafted wooden boxes will interact with a photo-book deployed on a tablet touch-screen device. Each printed photograph will be specially coded and, when detected by the digital photo-book, will unlock further, hidden content within it. As a digital object, the photo-book includes features that allow users in distant locations to comment on photographs and to curate and share their own chapters. Their engagement with the application will become part of the unfolding history of the village and its people.

The creative development of *Nostalgia Ti Frega* has drawn influence from several disciplines. Ideas around cultural change, including the effects of industrialization and globalization, the role of memory

and nostalgia in shaping identity; and the use of the imaginary within a shifting cultural context, are explored. The notion of the global village, including what it might consist of in a post-digital age, is a focus. Writing on haptic technologies and touch, and why these areas are increasingly important, has contributed to the creative framework, as has work in the area of material culture, particularly in relation to how objects relate to place and identity. Another important factor has been the use of user-centered design principles from the User Experience field of digital media. Developing out of the Human-Computer Interaction (HCI) discipline of Computer Science, UX principles are concerned with the effect (or emotional impact) on users when using digital products. Finally, the project also explores new approaches to storytelling, building on previous research that proposed a rhizomatic, nodal, non-linear storytelling framework specifically for interactive digital platforms.

THE VILLAGE

Salaparuta was a village of about 3000 people situated in the hills of Sicily's Belice valley, a few kilometres north of Santa Margherita di Belice and several kilometers west of Corleone. Like Santa Margherita, it had a castle and nobility, though after the reunification of Italy in the late 1800s and subsequent redistribution of land, the nobility left. Unlike Corleone, it was not a 'mafia' village.

The earthquake of 1968 was emphatic in its destruction. Several villages and towns were destroyed, 380 lives were lost, 1000 people injured, and 70,000 left homeless. With little local options available most of the population emigrated to Australia, Canada, the United States, and cities in the north of Italy. The rest camped in makeshift barracks and waited for new housing to be built nearby. Today the old village of Salaparuta is nothing more than over grown rubble; it is hard to distinguish where many buildings once stood.

As earthquakes go, the one that struck that winter was not a particularly strong one and, despite the tragic human casualties and destruction of property, did not come close to the catastrophic earthquakes Sicily's urban centers had experienced through history. However, unlike cities, which by their very nature are always in transformation and where destruction and redevelopment are customary elements and expectations of urban culture anyway, villages – usually understood as small hubs of human life in largely unpopulated landscapes – are very different entities. The entire physical presence of a village – its squares and meeting points, churches and cafes, thoroughfares and back-alleys – is intrinsic to how inhabitants socialize and interact, shelter from the environment and from strangers, and generally differentiate between the familiar and the unknown. In short, the physical space of the village is vital to an understanding of who, as a community, its inhabitants are and what their place, as a collective, in the world is.

While it can be argued that all spaces of habitation shape the identity of inhabitants, a village and its association with community, intimacy and belonging is understood to shape identity in a particular way. The notion of 'village' has in fact been used to understand and negotiate ideas around community and connection in many different contexts, from the destruction and redevelopment of urban landscapes, to the ability of mass communication to create a so-called 'global village.'

Traditional Sicilian culture is no different in this regard. The physical endurance of a village is a cultural reference point to the community that calls it home. It maintains continuity, is a reassuring anchor, and persists. So, when a village is destroyed and laid desolate, and, as in the case of Salaparuta, its people are scattered across the globe, what takes its place?

Even though not everyone from Salaparuta is directly related by blood, to be a *Salitanu* means to be part of an extended family of *paesani* (villagers) and to be treated as such. This extends to descendants as well, so that a child or grandchild (or great-grand-niece-twice-removed) is considered a member of the village, even if they have never been there. Clearly, many years after its destruction, a sense of Salaparuta persists. The village is no longer the same physical place it once was (at least not an inhabitable one) but it is certainly something somewhere in the hearts and minds of its people. It is this ‘something’ and ‘somewhere’ that *Nostalgia Ti Frega* seeks to explore.

NOSTALGIA AND IDENTITY

In his 1983 essay on postmodernism and consumer society, Fredric Jameson argued that the formal features of the post-modern world expressed the deeper logic of its social system; namely that it had “begun to lose its capacity to retain its own past, [had] begun to live in a perpetual present and in a perpetual change that obliterated traditions of the kind which all earlier social formations have had in one way or another to preserve.” [1] Jameson’s view was that people simultaneously lived in age that was radically disconnected from its past, but paradoxically, because of a pervasive nostalgia toward this lost past, were unable to articulate or describe the present or the very nature of their own environment.

He was essentially describing an identity crisis – the collapse of an established order and the resulting cultural void from which anything was yet to emerge. This is not unlike the migrant experience of the villagers of Salaparuta. The loss of old identity, precipitated through a physical disconnection to the homeland; a disconnection, creating a pervasive nostalgia towards the past; and this nostalgia, in turn preventing the emergence of new identities, are all hallmarks of what many migrants experience when adopting a new country as their home.

Jameson does not offer any way out of the bind he identifies. Dubious of our ability to experience what he saw in the 1980s as impossible dimensions, he calls for our bodies to “grow new organs, to expand our sensorium” and waits to see what the “new architecture” will bring. [2]

Over two decades later, it is clear that identity has certainly moved beyond Jameson’s postmodern stasis and is understood in ways suggesting we have indeed developed new dimensions. [3] Nostalgia too, rather than a stultifying, empty void, has grown new limbs, becoming something with the potential to enable hybrid, conflicting, previously impossible identities and histories.

In her 2001 book, *The Future of Nostalgia*, Svetlana Boym – an artist and migrant to the USA from the Soviet Union – dissects nostalgia into two prevalent types: “restorative,” which seeks the return to an original state and the recovery of an absolute truth (and which she aligns with nostalgic quests for restoration prevalent at the end of the 20th century) and “reflective,” which is a meditation on history and on the passage of time and perpetually defers a homecoming by cherishing shattered fragments of memory. “Reflective nostalgia does not pretend to rebuild the mythical place called home; it is enamored of distance, not of the referent itself. This type of nostalgia is ironic, inconclusive, and fragmentary.” [4]

Reflective nostalgia sits neatly in Boym’s artistic, Off-Modern art practice, “a detour into the unexplored potentials of the modern project.” [5] While *Nostalgia Ti Frega*, is not a radical experiment in terms of artistic expression, as Boym characterizes her art, it does embrace the notion of reflective nostalgia as a

tool through which to understand the paradoxical, hybrid, complex identities of its subjects, the *Salitane*, and their homeland today. As Boym states, “For many displaced people from all over the world, creative rethinking of nostalgia [is] not merely an artistic device but a strategy of survival, a way of making sense of the impossibility of homecoming.” [6]

MATERIAL CULTURE AND CONTAINMENT

Another focus of the project has been to consider the ways in which virtual ideas and emotions can be made manifest and expressed through material objects.

Part of this interest stems from the fact that photographs themselves, especially family photographs, are already objects that function in this manner. Historically, photographs and photographic objects have played important roles as repositories for both collective and individual memories, binding people to a sense of self and to each other. [7] Within Sicilian culture, photographs remain highly cherished objects with enormous emotional power. In the wake of the earthquake, when it was deemed safe to return to the village and recover what could be salvaged, photographs were considered highly valuable. They contained so many memories and emotions of lives now destroyed it is not surprising this was the case.

Photographs are also a potent example of how we use objects to understand ourselves and our relationships to others. In *The Comfort of Things* Daniel Miller demonstrates the manner in which people express themselves through their possessions, using them to both mediate interpersonal relationships and formulate a sense of self. [8] Greg Noble develops this approach in his work on the ‘cumulative self’ by considering the containers used to house our cherished objects. Specifically in relation to a shoebox containing photographs Noble writes:

The open-ness of the shoebox – [its] ability to function as [a form] of self-reflection and to undergo alteration – suggests that [it] be understood not in terms of containment as enclosure but as a form of containerisation, a holding together of objects for their safe transport. [It secures] the development of a stable but cumulative self because [it provides] both the mobilities and moorings necessary for ongoing existence in a complex world. [9]

Ideas around containment have clear synergies with reflective nostalgia – the ability for histories to be fragmentary and transformed by rearrangement, to offer more than one pathway, to move not in a single, straight, direction but inhabit many places at once. Given the evolving and emergent nature of the community at the centre of *Nostalgia Ti Frega*, incorporating technologies of containment into the project is a way to cradle the ever-shifting community identity, and also participate in its formation. Moreover, it enables the analog/physical aspects of the project (the wooden shoe-box) the ability to provide an emergent story experience, one the digital photo-book application will similarly provide.

POST-DIGITAL, POST-ARTIFACT

Rapid developments over the last two decades in telecommunications, digital technology, and interactive media, mean that people and communities can now connect in new ways. Identity and belonging are increasingly mediated through connections that take place in ‘virtual’ space and photographs are playing an important role in these connections. [10] *Nostalgia Ti Frega* takes its place within this digital

world by being presented, in part, on a tablet touchscreen digital device. Like the box for physical photographs, the tablet serves as a 'container' for the digital application. The size and mobility of tablet devices make them especially suited for this.

Importantly, tablet devices are heralding an interface paradigm shift away from the mouse towards touch – as the mouse transformed the possibilities of user interfaces, so too will touch and gestural interaction. Tablet-touch devices are relatively new, and innovative examples of narrative photographic applications for them still relatively rare. *Nostalgia Ti Frega* will explore the potential these devices offer, both from a user interaction point-of-view, and in relation to dynamic non-linear story experiences, ones that users themselves are able to contribute to. Incorporating ideas from reflective nostalgia into the user experience design, the application will be a platform where content can be transformed and re-arranged, story progression will not be singular or linear, and multiple-versions of the same story are possible.

This intent also neatly extends previous research completed as part of Masters studies in interactive multimedia. There, drawing correlations between 'experience,' as understood by information architects, and 'story,' as understood by film and television practitioners, I highlighted the importance of storytelling in the design of interactive forms of media, especially in contexts where traditional forms of storytelling were no longer as compelling. Using the concept of Rhizomatics, as described by Deleuze and Guittari (and taken up by others) as a basis, I suggested that an active and participatory experience design in digital interactive contexts be informed by non-linear methodologies of narrative. [11] *Nostalgia Ti Frega's* conceptual framework, informed so heavily by ideas from reflective nostalgia and containment, is an opportunity to experiment with this approach.

However, while digital technology has changed the types of social connections and stories we can now experience, we, and our world, are still physical entities. We exist in and in relation to a material world, and, as significant as our virtual connections may have become, our material context is still present and, crucially, still significant. Carol Wilder has speculated that our resistance to digital technology is because the experience of what we perceive to be more 'real' is more valuable to us than the experience of the high-tech. [12] Sherry Turkle goes even further in her 2011 publication, *Alone Together*, surmising that technology's increasing domination of our lives threatens to make us less human: "Under the illusion of allowing us to communicate better, it is actually isolating us from real human interactions in a cyber-reality that is a poor imitation of the real world." [13]

Creating a photographic work that embraces the potential of digital interactivity, while also keeping a firm anchor in the realm of the material, is a timely project. As such, the project – both digital and analog aspects of it – sits firmly within the paradigm of what Craig Mod has termed 'post-artifact': "ethereal and networked, emerging publicly in fits and starts. An 'artifact' complete for only the briefest of moments. Shifting deliberately. Layered with our shared marginalia. And demanding engagement with the promise of community implicit in its form." [14]

Ferdinando Scianna, one of Sicily's most preeminent photographers, began his career by documenting the changing culture of his own hometown. In the 2002 retrospective publication of this work, *Quelli Di Bagheria*, he stated: "I believe that the ultimate ambition for a photograph is that it end up in a family album." [15] In many ways, *Nostalgia Ti Frega* can be thought of as a new kind of family album, one specific to a post-digital, post-artifact age.

ARTISTS AS THE NEW PRODUCERS OF THE COMMON (?)

ATHANASIA DAPHNE DRAGONA

This paper examines a new form of creativity, based on the commons. Using two projects organized in 2010 by the National Museum of Contemporary Art in Athens as case studies, it aims to define the features of this emerging creativity and to locate the challenges and changes formed for the creators involved in this process.

Paolo Virno writes that post-fordism is the era of the "communism of the capital." [1] The notion, which may be heard as a political (pseudo) paradox of our times describing a capital based on communality, is not a new form of utopia, however, it rather implies a new kind of accumulation and creation of value based on the expropriation of the common. Knowledge, information, affects, codes, social relations, the new 'artificial' common wealth, which is not inherited but is produced and shared by the 'posse' – the potentiality – of the contemporary multitude, is what is at stake and what is being capitalized today according to the Italian school of thought. Produced in the contemporary metropolis and the networked spaces we have come to inhabit, the common is the multitude's strength and its Achilles's heel at the same time. Continuously becoming and constantly expropriated, being abundant, dynamic and diffused, it can only be understood as a derivative of a life in excess and a life open to appropriation and control. Therefore, the 'communism of the capital' is an oxymoron expressing the controversies and questionings of the post-fordist condition. How can the multitude's capacities to think, to produce and exchange information and knowledge escape capitalization? How can they be reclaimed and by whom? If there is no longer an outside, as it is often being said, is there maybe a possibility for a change, which would derive from within?

This paper looks into the role of art in the years of the new common wealth. Taking into consideration the great number of projects which have been developed in the last decade and the references made to creativity in the context of the new discussion on the commons, a double-sided observation is attempted; not only on how forms of art encourage a swift of mentality towards the commons, but also on how the art world itself changes through this process.

The starting point for this positioning will be two projects initiated and curated by myself and organized by the National Museum of Contemporary Art, Athens, in 2010, the year when Greece started losing its financial independence. Seeking alternatives in the impasse of late capitalism, *Esse, Nosse, Posse: Common Wealth for Common People* and *Mapping the Commons, Athens* aimed to examine and locate the commons in their two main reservoirs, the Internet and the city.

Esse, Nosse, Posse: Common Wealth for Common People

Esse, Nosse, Posse: Common Wealth for Common People is an online platform launched in April 2010, as an open comment to the growing common wealth of the connected society. [2] The title is a reference to the Latin triad "I am, I know, I can," that having constituted the core of renaissance humanism, today interestingly reappears in order to describe the features of the contemporary multitude. [3] What is important is not only the knowledge itself but also our potential for its production and the formation of our subjectivities through it at the same time. Taking this into consideration, the online platform aimed

to refer –through a rich variety of artistic creation – to the motivations and capacities that form the new common wealth and to respectively discuss the controversies and risks lying behind it. To achieve this, *Esse, Nosse, Posse: Common Wealth for Common People* hosted: a) projects critically commenting on the new forms of networked wealth and b) initiatives and open platforms based on free and open software, encouraging exchange and collaboration. Selected texts were also uploaded as resources to provide a context for further discussion.

The issues tackled by the projects that were presented were the following: the passage from the fordist to the post-fordist society and the transformation of labor (*First of May* by Marcelo Exposito), the immeasurability of the immaterial work conducted in the networks (*User Labor* by Burak Arıkan and Engin Erdogan), the new forms of online labor based on virtual sweatshops (*Invisible Threads* by Jeff Crouse and Stephanie Rothenberg; *Gold Farmers* by Ge Jin aka Jingle) or on crowdsourcing (*Bicycle Built for 2,000* by Aaron Koblin and Daniel Massey; *re_potemkin* by .-_-.), the call for a free exchange of knowledge beyond copyrights (*Free Culture Game* by Molleindustria; *Perpetual Wall* by Dimitris Papadatos), the interweaved character of the networked economy (*All Over* by Samuel Bianchini), the imbalance of the information society (*Internet Art for Poor People* by Carlos Katastrofsky; *MAICgregator* by Nicholas Knouf), and the value of attention economy in territories of info-noise (*Falling Times* by Michael Bielicky and Kamila B. Richter).

While the above works were discussing the capitalist character of the networked condition, the platforms, that were also introduced, invited users to join efforts of collaboration, co-production and knowledge sharing. Initiatives by collectives with significant work in the field were listed, such as: Furtherfield, who encourage people to recycle their old laptops by offering them to the homeless (*The Zero Dollar Laptop*); Platoniq, who propose a platform of exchanging services (*The Bank of Common Knowledge*); or Mediashed who propose that people communicate their low cost products through their database (*Gearbox*). Escaping capitalization, control and appropriation, these efforts propose to users a different mode of engagement and production in the networks. At the same time, projects with a more specific character were also included. Such as the platform of Anders Weberg (*P2P Art*) who invites people to participate in the creation of an ephemeral common artwork based on peer-to-peer logic, or Brett Gaylor's *Open Source Cinema*, which invites users to upload and remix the videos online. The Artzilla team has also been included for its web browser modifications and subversions that support freedom and openness, along with the Shiftspace group who, in a similar approach, propose the placement of open source layers above any website. In addition, the network Kate Rich created for the fair trade of products is presented (*Feral Trade*), as is Dmitri Kleiner's *Telecommunisten* network, which offers tools and services that are owned by the workers themselves.

A new utopia or a breakthrough in the networked world? This entity of projects is only part of an emerging creativity on the Web which is based on the idea of the commons. However, can we realize our potential and re-orientate our disposal for socialization and knowledge towards the new liberated environments the artists propose? We might be in the beginning of a shift in mentality, yet it should be noted that the initiatives and actions discussed in the context of this paper are not being valued on the basis of their popularity or 'efficiency.' They are considered noteworthy for the stance that their creators take. What lies behind them is a call, an urge for a new system of values that can empower the growing common wealth. These values are to be found not solely within the Web, but also within life itself and especially in its most lively terrain, which is the contemporary metropolis.

Mapping the Commons, Athens

Mapping the Commons, Athens was a cartography project that followed *Esse, Nosse, Posse* reflecting a need to trace the commons in the urban environment and to examine their role in times of crisis. The project took the form of a cartography workshop conceptualized by the Spanish collective Hackitectura, which was commissioned by and hosted in the premises of the National Museum of Contemporary Art, Athens in December 2010. [4] The aim was clear: to map the city of Athens, restless and vulnerable as it was, according to its commons. The work was undertaken by an interdisciplinary group of artists and researchers from the universities of Athens, guided and supervised by Hackitectura; with contributions from artists, sociologists, scientists and theorists working on the field.

Seeing beyond the 'public' and the 'private,' the team sought for, examined and documented the different types of commons that were located in the urban environment. The elements of sociability, openness, sharing and accessibility were of primary importance during this exploration; special attention was given to peer-to-peer practices, community networks and forms of exchange economy. The entries enriching the cartography were decided and organized according to certain parameters related to the 'wealth' being produced, the community supporting it and the risks of its enclosure and exploitation.

The team successfully produced two maps: a research map, where all commons were described, categorized and located; and a video map where certain commons were developed into video case studies by the participants. Furthermore, a blog documenting the progress of the workshop was also created. However, the most important outcome of the project was the 'common' produced during the workshop itself; the knowledge that the community of creators, students, artists and theorists formed together while also building a common experience and imaginary.

Locating the features of common-based art

Taking the above works as examples, one can interestingly locate similarities that assist in recognizing the features of a new form of creativity which emerges on the basis of the common. The rich variety of works discussed – which may be categorized as net art, game art, software art; or as documentaries, interventions, databases and maps – all share a kind of openness and collectiveness which opposes previous ways of perception and evaluation in the contemporary art or new media art scene.

In an attempt to locate and summarize some of the main features of this creativity, the following points could be used as a start:

- The works, in their wide variety, do not constitute art objects or art installations; they present no certain aura and claim no art market value.
- They accordingly do not aim for the awe of the spectator; they do not impress by their aesthetics, techniques or complexity.
- They claim no authorship and no uniqueness; their power is in their distribution and diffusion.
- They are not cryptic or ironic; on the contrary, they aim to be direct, understandable and reachable.
- They address the citizens and users of the cities and the networks and not specifically the art audience, the art institutions or the art collectors.

The aim of this growing entity of works seems to be no other than to socialize knowledge. They are works that, as Matteo Pasquinelli expressed it, belong to the age of "social reproducibility," [5] which

followed Benjamin's age of 'mechanical reproduction.' We have gone beyond the unlimited reproduction of artistic objects and the loss of the aura of the prototype. The challenge for the works of art is a new one; it is the challenge for a "unicity without aura" as Virno put it, for a "non-original unicity which originates in the anonymous and impersonal character of the technical reproduction." Art's new aim, he argues, is to find the relation between the highest possible degree of communality or generality and the highest possible degree of singularity, the balance between the most general and the most particular .

[6] Are the works previously mentioned not a first step towards this direction as they refer to the common wealth produced by the general intellect on one hand and to the importance of the contribution of each singularity on the other? Is the presence of the artist's identity not lessened as works seek for a new balance between individuality and collectivity? Or rather between "multiplicity of individual expression and the unity of a collective will," between "singularity and solidarity, cooperation and freedom?"

[7]

This realization, however, leads to the need for the second definition: who are the creators that seek this new balance expressed as a "unicity without aura" for their works and why?

Describing the creators of commons based art/the new commoners

Discussing works based on collectivity, openness and lack of authorship, it easily becomes clear that we mostly refer to creators who are leaving the role of the 'artist' and moving towards the one of the initiator, the collaborator, the affective worker, the networked creator, the hacktivist. Often, the creators might not even be artists. In their shoes there are programmers, architects, lawyers, social scientists, or generally people from different fields who see creativity as an invaluable tool of expression, communication and resistance. This is a new generation of creators who wishes to merge with the 'audience,' blurring prior boundaries and hierarchies. What brings them together is the virtuosity, the social competences and the affective potentialities they all have and use in their virtual and urban interactions. For Virno, who assigns to virtuosity a central role for the post-fordist way of being, and sees creativity as diffused today, "each and every individual is, *at the same time*, the artist performing the action and the audience: he performs individually while he assists the other's performances." [8]

But what does such a realization mean? Do artists still have a role to play or they fade in the name of a new common and radical approach of creativity?

At this point, one needs to pause and reflect on some of the fundamental ideas of the common wealth on one hand and on the actions of the creators being discussed on the other. "There is no commons without commoning," wrote Peter Linebaugh, highlighting the fact that besides the common goods, the social practices of a community are also needed. There is no commons without the commoners; these are the individuals that not only produce and share the commons but also establish relationships of solidarity between them and fight to reclaim the commons that have been enclosed. While Linebaugh refers to the 'Magna Carta,' the commoners of the medieval England and the land enclosures, one could interestingly juxtapose this sequence to the inhabitants of today's cities and networks with the enclosure of the common wealth produced. What seems to be missing, however, is the cultural memory of a prior different mode of being and sharing that the commoners of land had, reminding them what there was to be reclaimed. [9] Missing this element, an urge for a common imaginary appears that – replacing common memory – will be based on the realization of the multitude's potentialities and will offer the ground to step on in order to reclaim the surplus of the knowledge and information which is being en-

closed today. A form of this common imaginary is what the creators are building through their initiatives, activating through it the shaping of new communities and new commons. Seeing artists as the new commoners therefore is the first point that can be made regarding their contribution.

A second point can become clear while looking into the formation of the new common spaces that the artists are particularly proposing which are beyond control and exploitation. The online collaborative platforms, the databases of exchange or the workshops organized can be seen as the new interconnected spaces that allow communities of commoners to be formed, offering to the worrying and restless multitude a new home and a new ground for social encounters.

Thirdly, the creators today may assist the contemporary digital multitude by encouraging the use of the tools that we all already have in our possession. What we need today is to learn how to work with language, codes, ideas and affects; and how to build relationships through them. [10] We need the knowledge and information infrastructure that artistic creation seems to be able to provide while avoiding at the same time the appropriation of these tools on the web and in the city environment by third parties.

Finally and hopefully, through such a process a new system and a new theory of value can emerge, one which would express the desire of the multitude for a liberated connectivity. As life is in excess today, as work and life have become one, a new balance can only be found through creativity that embraces the ideas of sharing and co-producing.

Reclaiming a new form of exodus

Open, participatory and rhizomatic, the new form of art emerging based on the commons seems to have some of the features that media art did not reach before. It is a form of art that tries to assist, to engage with the audience and to share knowledge. It informs and encourages transformation; it takes responsibility and helps the multitude to overcome its fears.

Although this new form of creation could be related to certain movements of art history such as Dada, for its recycling practices and its negation towards artist's authorship, to Situationism for its refusal to copyright, or to the movements of institutional critique; yet the creativity based on the commons presents an interesting differentiation. It is not necessarily anti-art or anti-institutional. It alternatively takes a stance or a point of view that looks beyond the art system and the art world. The artists do not negate art or the museums' structures and hierarchies. They often choose to address to them and propose new forms of collaboration that will need to be based on new grounds of openness and sharing. They often invite institutions to enter a game based on openness and diffusion of information and to surpass the constraints of ownership and authorship that might have impeded such an orientation. They ask museums to join their efforts towards the commons by providing the audiences a context for art practices related to sharing, by encouraging and presenting creators' alternatives to capitalism, by assisting in the formation of new common places and common values beyond institutional walls.

Facing the impasse of late capitalism, the creators of the works that were discussed in this context, seem to ultimately aim for a new form of exodus. This exodus however can only come from within, by staying where we are and by expressing a collective will for a change. The idea therefore is to "pursue a line of flight while staying right here, by transforming the relations of production and mode of social organization under which we live." [11] For this reason, the efforts of the creators to reach out and communicate ideas, to overcome themselves as names and overcome art as art, assist in the formation of a

multitude of commoners that can achieve direct experiences of co-operation beyond exploitation. This is a value that is worth noting and supporting for years to come.

This research has been co-financed by the European Union (European Social Fund – ESF) and Greek national funds through the Operational Program "Education and Lifelong Learning" of the National Strategic Reference Framework (NSRF) – Research Funding Program: Heracleitus II. RE-CONQUERING THE GAMIFIED CITY: AN OLD BATTLE ON A NEW URBAN GROUND

ATHANASIA DAPHNE DRAGONA

What does the notion of gamification imply for the urban environment? In the last few years, images of new adventurous cities have appeared which offer excitement, fun and socializing to citizens who are full of energy and desire for challenges, rewards and status recognition. Is this an expanded gaming territory or an unfortunate ludic decadence? This paper addresses gamification by looking into an old battle, situated between 'game' and 'play.'

In the last few years, a new challenge appeared for the inhabitants of cities around the world. Gamification, the strategy of applying game dynamics and mechanics into non-game contexts, reached the contemporary metropolises and created a new ludic layer over them. Challenges, points and levels have been integrated into the urban environment inviting citizens to act as players and compete for achievements, awards and status recognition. Designed by location-based social networking sites, the new motivations for urban exploration are based on two fundamental human characteristics: our sociality and disposal for play. Being rewarded "for doing new things and for making a better effort to be social," the players engage successfully not only with different everyday activities, but also with life itself writes Jane McGonigal, arguing that the application of pleasurable game elements can actually assist in restructuring society in better ways. [1] While, according to this line of thought, a great game-based future might be opening ahead of us, one cannot help being reserved when confronted with such positivism. On which grounds does gamification really stand? This short paper will aim to discuss gamification by locating the contradictions and misrepresentations connected to it on one hand, and by situating the potentialities for its surpass on the other.

Gamification is a term describing a process applied not only to the urban environment but to a wider range of sectors, such as those of health, education, labor and the Internet, with a common aim: to affect and manipulate human behavior for the favor of the market. Although McGonigal chooses not refer to the market but to praise the process as a decisive solution for the impasse of today's reality, most of the gamification supporters directly discuss the possibilities game-like processes may offer to generate more customers, more advertisements, more revenue. For this reason, since its beginning, gamification has been met with hesitation by scholars from the field of game studies. Described as "exploitation-ware," [2] or as "a tactic employed by repressive, authoritarian regimes," [3] gamification has been doubted for its aims and values. The world might have always resembled a game, but never before did this resemblance manage to make profit per se.

Complementary to this first argument, a number of logical points can follow regarding the sense and impact of applying game dynamics and game mechanics to urban life. Do we really need extrinsic awards, for instance, in order to wander around in the city and decide where to stop? Do we need extrinsic motivation to meet our friends? Is having our movements and interactions tracked, controlled and used by third parties worth it, for the fun of the game? Gamification has therefore received a lot of critique not only for the profit that it generates but also for the devaluation of human activities that it encourages.

In addition to the above, scholars doubt the influence of the integration of points and awards into a non-game activity and the characterization of it as a game; these elements are actually the less important aspect of a game they argue. However, either the game resemblance is accurate enough or not: the features and techniques used are sufficient to trace the revival of an old battle between two fundamental notions, those of 'play' and 'game.' By setting rules and constraints, by enclosing certain locations in the map while ignoring others and by limiting the citizen's openness and freedom of choice, gamification's preference towards the 'game' becomes clear. Or, to remember Roger Caillois, 'paidia' seems to be defeated by 'ludus,' as the "arbitrary, imperative and purposely tedious conventions" of the latter take over the gamespace and push away the "frolic and impulsive exuberance"; the "anarchic and capricious nature" of the former. [4] The formation of the new controlled city, seems therefore to be in complete antithesis with what the Situationists once envisioned as the playful city, or more particularly with what Constant framed as the 'New Babylon.'

What a sad reversal and a disappointing cancellation of the revolutionary ludic thoughts of the past, one could note while reflecting on the 'New Babylon.' What a swap in the use of technology: from a means of liberation to a means of control, from the city planned for 'Homo Ludens' to a city planned for playful work. The 'New Babylon,' a city for play, leisure and adventure, a city where work would be automated and man would be free as in a utopian city. However, no one expected such a realistic misrepresentation of it where 'Homo Ludens' would become again 'Homo Faber,' seduced by game gimmicks and fouled by the impression that the game like interfaces of technology could empower him over the city. Although Constant wisely predicted the exciting ludic behavior the advance of technology and telecommunications would bring, little could he foresee the expropriation that would also follow. A city of movement, based on dynamic relationships between citizens and the urban environment was realized, but based on the inhabitants' disposal, sociality and potentiality.

In reality, the new gamified cities perfectly fit into the context of the post-fordist metropolises, of the new city factories where the multitude lives. The contemporary cities based on our knowledge, information, codes and social affects are being gamified; inviting us to produce more, while collaborating and/or competing with our friends. Gamification is in perfect alignment with the new modes of immaterial and affective production. We produce as we play. We work as we interact. The new realistic perception of ludic cities is based on our capacities and potentialities. However, for this same reason, no dead end has been reached yet: gamification can be opposed and this is possible only by again embracing play itself.

While a gamified image of the city is being created by interfaces, a different documentation of the contemporary metropolis manifests playfulness as an immanent element of today's multitude. The fragmented, anarchical, diverse and incoherent multitude in times of crisis and transition uses play to express and highlight its opposition and resistance. Masks, movements, actions appear spontaneously within gatherings and demonstrations. "The anger of the protesters coexists with their joy in the carnival," as Hardt and Negri note. "The protests are carnivalesque, not only in their atmosphere but also in their organization," which shows an enormous capacity for innovation; innovation to transform reality itself. [5] To see this image one needs to turn from the mobile interface to the image of the square, from the controlled gamespace of the market to the reclaimed public space of the city. The anarchical, impulsive elements of paidia are apparent; one only needs to set his eyes on the practices of the urban players around us. At stake today, therefore, are the potentialities of today's players/citizens, which can easily be used for the profit of the market through game like interfaces, or for the benefit of the common through tactics of playfulness. For the latter direction, players/citizens need to realize not only the set of possibilities offered in today's city gamespaces but also the ways value can be generated and exploited with their involvement.

In other words, we need to keep going back to understanding the rules and constraints of the 'game' and to being critical and playful at the same time. Else, the gamified corporate reality will slowly abolish common play. At that point, we might even be driven to a manifestation of a call to "Never Play" following the "Never Work" of the Situationists as a form of resistance, as McKenzie Wark writes in his latest book. [6] Could we prevent the ultimate ludic downfall of our times?

BIOSENSING AND NETWORKED PERFORMANCE WORKSHOP

Anna Dumitriu

The Biosensing and Networked Performance workshops led by Anna Dumitriu and Tom Keene enable participants to build and calibrate their own iPhone compatible Galvanic Skin Response Sensors (GSR), which enable recording of subtle changes in the user's emotional arousal. Participants then collaborate to develop a networked performance that engages with the ethical implications of disclosing such personal information within the public realm.

"Biosensing and Networked Performance" by Anna Dumitriu & Tom Keene, materials: electrical components, smartphone. Photograph copyright Anna Dumitriu.

Participants learn to solder and connect their own GSR sensors, connect them to their iPhones and share their sensor data online. The workshops create a framework for debate around the implications of new social networking and pervasive computing technologies and the increasing issues of privacy as, increasingly, our most personal details can be recorded and shared. Finally participants work with the workshop leaders to improvise, plan and rehearse an intervention performance work that is performed at the end of the workshop. This performance may be very subtle and not immediately obvious to any (unwitting) audience members that may be around, playing with ideas of what we do and do not reveal to those around us both in the physical and digital sphere.

The project builds upon artistic research undertaken by Anna Dumitriu in her role as artist partner on an EPSRC funded project "Supporting Shy Users in Pervasive Computing" working with an interdisciplinary team of sociologists, computer scientists and human-computer interaction specialists at The University of Sussex. The project is investigating how pervasive computing is changing the ways social interactions occur, how we are becoming socially present in an increasing number of ways (sometimes without even realizing it), what our digital presences say about us through the data that is being recorded and how that data can be used.

Whilst in some ways technology may enable a reassuring sense of invisibility and anonymity (in terms of creating digital avatars and being able to use false names) it can also lead to obsession with self-image, fears about how one is perceived and confusion about how to present oneself or how to behave. This can lead to a feeling that there is a need to 'perform' and a sense of being laid bare, even provoking a form of 'stage fright' as described by sociologist Susie Scott an investigator on the project:

"...feelings of shyness arise when one perceives oneself as relatively incompetent at interaction, and fears being exposed as a poor team player. If we anticipate that we will say or do 'the wrong thing' and face embarrassment, surely it makes perfect sense to defend oneself emotionally by remaining quiet and avoiding the spotlight of a front-stage performance." (Scott, 2006)

Interactive digital art is a useful example of a piece of technology that is intended to promote high levels of engagement but can often evoke feelings of shyness in visitors, as the works presume that visitors are actively engaged and willing to 'find their own ways' through a work and explore how to playfully interact with it. Ironically sociologists' findings from this large-scale project show that the *majority* of visitors feel they lack the competence to actively engage with interactive art (and this includes artists and gallerists), especially in front of others that they perceive to be more confident performers. Intimidated, they tend to feel that there is a set of rules that others are aware of and that they do not have access to. So they prefer to fade in to the background rather than let the side down by failing to perform 'in the correct way'. Scott argues:

"Shyness is a normal, socially intelligible and communicatively rational (Crossley 2000) response to dramaturgically stressful situations. Shyness involves a feeling of relative social incompetence: of 'not knowing the rules' of social situations, as if there is a 'right' way to manage them. This is accompanied by a perception of 'Competent Others' around oneself who do appear to understand these rules and seem better equipped to perform appropriately. When faced with this risk of 'getting it wrong', being embarrassed, being scrutinized and judged by a critical audience, inhibition makes absolute sense as a dramaturgical response." (Scott, 2007)

In response to this research, the Biosensing and Networked Performance workshops seek to engage participants not only in the hands on building of the technology they are working with but, importantly, in the creation of a set of rules that will be used to generate new performance work of their own making.

The simple biosensor device used in the workshop is a Galvanic Skin Response sensor (made using easy to find components and a 'hardware hacker' approach) that measures the electrical conductance of the skin and can be attached to a wearer's finger to measure subtle changes in sweat levels. Sweat glands are controlled by the sympathetic nervous system so skin conductance is a useful indication of fluctuations in psychological or physiological arousal. The data produced by the device is then input into the iPhone via its headphone socket and uploaded to an online sensor data sharing facility using a method developed by Keene.

As arousal levels reach certain thresholds they can be used to trigger text messages and other outputs via a software interface written by Alex May (based on work done by ESKINDIR ASMARE as part of the wider research project). These text messages are part of a predetermined script for a generative performance written by the workshop participants. Based on the GSR data from one member of the group, the others can enact various 'flash mob' style behaviours. For example members of the group may drop their knees in unison on receiving a certain text message cue, others around them having no idea what the trigger for this was. However actions may be far subtler such as participants yawning in unison or even just touching the corners of their eyes, almost imperceptibly. The rules, the behaviours and the text messages are invented as part of the workshops.

In many ways the idea of sharing your emotional states online is a difficult issue. Technically GSR is not an ideal method. The only genuinely effective method for scientifically describing emotions is functional magnetic resonance imaging (fMRI) and this is not in any way portable. But the most problematic issue is already with us: pressure from others to subscribe. It is already the case that some employers insist that employees register with location tracking systems such as Google Latitude. Not only that but parents also use the same software to track children and partners to track loved ones. It is difficult to extricate oneself from being tracked if it is not desirable. How do you tell a loved one 'I no longer wish you to know where I am'? It would be even harder to say 'I no longer wish you to know how I feel' even if at the start of a new relationship you enjoyed sharing every inner secret, this may not always be the case.

Reflection on key issues around developments in pervasive computing is central to the development of the work and the workshops consider what the future possibilities and implications of ubiquitous biosensor data sharing might be; they look at what ethical issues need to be considered; how technologies impact users on a personal level? (This includes the impact on "shy users") and what the technical difficulties of implementing the automated sharing of emotions via ubiquitous technologies are.

COMMUNICATING BACTERIA

Anna Dumitriu

The *Communicating Bacteria* Project combines bioart, historical textile techniques and 3D mapped video projections to explore new research currently being undertaken in the field of bacterial communication, to engage a wide audience in the field and increase debate and understanding of this potentially new form of infection control. The project is funded by The Wellcome Trust.

"Communicating Bacteria" by Anna Dumitriu, medium: antique embroidery, contemporary embroidery and bacterial pigments. Photograph copyright Anna Dumitriu.

Bacteria have intricate communication capabilities, for example: quorum sensing (voting on issues affecting the colony and signaling their presence to other bacteria); chemotactic signaling (detecting harmful or favorable substances in the environment); and plasmid exchange (e.g. for transfer of antibiotic resistance genes). This is now being investigated as a form of social intelligence as it is realized that these so called 'simplest' of life forms can work collectively, obtain information about their environment (and other cells) and use that information in a 'meaningful' way. Using signaling chemicals such as *Homoserine Lactone*, the bacteria pass on messages to nearby cells, which can be either part of their colony or other living cells (including eukaryotic and plant cells).

The project is led by artist Anna Dumitriu; in collaboration with microbiologists Dr Simon Park and Dr John Paul, and video artist Alex May. Dumitriu's long-term artistic practice is focused around microbiology and collaborative practice. *Communicating Bacteria* [1] builds strongly on her earlier work – including *Cybernetic Bacteria 2.0*, a digital media installation presented at ISEA 2010 – and current role as artist in residence on the on the UK Clinical Research Consortium *Modernising Medical Microbiol-*

ogy Project at The University of Oxford, Nuffield Centre for Clinical Medicine, which looks at the changing face of medical microbiology in light of the possibilities of (near) real-time genome mapping of bacteria and developments in bioinformatics.

The importance of the public understanding of microbiology cannot be understated. Many businesses play on public fears in order to add value to their products, while newspapers and TV shows fill our minds with images of bacteria as armies of tiny monsters ready to attack unless we buy some new hand wash or detergent.

The infection control potential of interfering with bacterial communication and quorum sensing mechanisms is at an early stage, however it is known that:

This 'census-taking' enables the group to express specific genes only at particular population densities. Quorum sensing is widespread; it occurs in numerous Gram-negative and Gram-positive bacteria. In general, processes controlled by quorum sensing are ones that are unproductive when undertaken by an individual bacterium but become effective when undertaken by the group. For example, quorum sensing controls bioluminescence, secretion of virulence factors, sporulation, and conjugation. Thus, quorum sensing is a mechanism that allows bacteria to function as multi-cellular organisms. [2]

Therefore, the ability to block the receptors that receive quorum sensing signals would lead to bacteria that are no longer able to turn on those processes. To be able to block the expression of virulence factors (such as bacterial toxins) would render highly pathogenic organisms far less dangerous. Further down the line an understanding of the exact signaling mechanisms might even lead to the possibility of directing the behavior of bacteria.

The *Communicating Bacteria* Project involves the development of a body of new work, including: textile designs stained with dyes made from bacteria that change colour depending on the behaviour and communication of bacteria, crochet patterns based on bacterial responses, interactive interventions that are modeled according to behavior and communication between bacteria, and a series of hacked antique whitework embroidered pieces created using genetically modified bacteria.

Textile art has a long history of communicating difficult and complex stories and ideas, from the Bayeux Tapestry to the AIDS Memorial Quilt. The soft qualities of the fabric and the skills of the makers help to reach out to a wide audience of all ages. Dr Simon Park had previously created a number of previous works involving the staining of cloth with bacterial pigments (and slime moulds) and his expertise and inspiration was integral in the development of this project.

The antique whitework (white on white) embroideries are worked in to by hand with delicately stitched images of bacteria and communications networks. Dumitriu's modern stitches are far heavier handed than those of the original makers, creating an interesting juxtaposition. Additional patterns are created using a genetically modified strain of *Chromobacterium violaceum* called CV026. *Chromobacterium violaceum* is white in its natural state but turns purple when it receives a communication; but, since bacteria grow in colonies and individual bacteria are continually sending and receiving signals it always appears purple. However, the CV026 strain is effectively mute. It can receive a chemical communication signal but cannot send one, so it only turns purple in the presence of a communication from another bacterium. When exposed to unmodified *Chromobacterium violaceum* it slowly turns purple as the chemical signal spreads.

Around the time of the enlightenment, the perversely difficult practice of whitework embroidery was considered to be one of the highest levels of achievement for a woman. They would sew in the evenings by candlelight, straining their eyes to see the tiny stitches, hunched over their embroidery hoops, their bodies twisted and constricted by tight corsetry, one pinprick of blood meaning the whole piece would be ruined. This coincided with the period in which many of their male counterparts started to become 'gentleman scientists' and to rigorously study the world around them 'scientifically.' This was the time when the scientific method was developed and disciplinary boundaries were drawn between art and science. By juxtaposing whitework with her scientific practice, Dumitriu considers these paradigmatic changes in the process of research and current moves towards transdisciplinarity, alongside a consideration of what 'feminine' approaches to science might mean.

Central to the installation is a stunning antique Edwardian whitework dress, with Dumitriu's additional stitching and a purple pattern created by the process of bacterial communication. The dress was laid out on a one meter square agar plate (a makeshift Petri dish from a DIY centre normally used for mixing concrete and sterilized with ethanol), inoculated with CV026 and left to grow, be absorbed into the fibers and travel along the fine stitches. After a day or so of incubation the white CV026 was exposed to the *Chromobacterium violaceum* and the communication signal traveled across the fabric as the white bacteria turned purple. This process was filmed using time-lapse photography and the resulting film was projected, using 3D video mapping technology (developed by Alex May) across the dress and related objects within the final installation. The dress having been dried, sterilized and made safe.

The project continues to be developed and work is now being undertaken to develop methods to exhibit the process taking place live and run participatory sessions working with the team. This entails the development of a modular Category Two bio-containment facility that can be constructed within art gallery settings, whilst fully conforming to health and safety requirements and enabling a much deeper level of engagement and understanding of these complex microbiological processes through a powerful and experiential artistic approach.

THE EMERGENCE OF CONSCIOUSNESS

Anna Dumitriu

The Emergence of Consciousness project is an artistic investigation of the scientific study of consciousness and the possibilities of 'machine consciousness' through the use of performance art and digital media. Dumitriu worked with sensory and movement deprivation (e.g. blindfolds, physical restraints etc.) and augmentation, in an attempt to take on the role of a robotic agent herself and try to understand what it *feels* like to be a robot.

"The Emergence of Consciousness" by Anna Dumitriu, performance with Bondage tape, lidocaine, robot, earplugs and digital projections, photograph copyright Anna Dumitriu.

The issue is that we tend to think we know what a *conscious* experience is and our inner mental lives are filled with assumptions about the conscious experiences of others, we believe we know how they feel and we assume they have some insight into what how we feel. We have what's known as a "theory of mind" and are able to identify other "minded" subjects. But these abilities are set to be thrown into question as developments in artificial life (AL) technologies lead to the potential to build robots that give the impression of being "minded" in some way. Thomas Nagel's paper "What is it like to be a bat" suggests that it is not possible for us to imagine how it would feel to be a bat because bats use sonar to navigate their world, something we could not imagine as we have no understanding or experience of it. However technological advances may offer us limited access to "new" senses, even in the short term and we can learn to incorporate them, perhaps enabling new insights. An example of this is the "Enactive Torch" built by Tom Froese and Adam Spiers, which: "provides the user with one continuous channel of vibro-tactile feedback to the hand, where the strength of stimulation depends on the distance to the object which is currently pointed at. The distance is measured using an ultrasonic sensor."

Working closely with researchers from the Centre for Computational Neuroscience and Robotics at The University of Sussex during her artist's residency there Dumitriu investigated notions of what "conscious

experience” might mean for a robotic agent in contrast to a human (the artist herself). The project, which was created as part of the London 2012 Cultural Olympiad is inspired by perspectives of embodiment as characterized by Francisco Varela, Evan Thompson and Eleanor Rosch, and situatedness as applied to evolutionary robotics by Rodney Brooks. This research was used to develop a new work, which was performed at Lighthouse in Brighton in July 2010. For the piece Dumitriu attempted to take on the role of a robot agent by reducing (as much as humanly possible) her sensory input down to that of her collaborator a medium sized robot whose only interaction with the world is through its limited sensors and wheels). Working with an assistant (Luke Robert Mason) her ears were blocked with earplugs, her head and body were wrapped in thick black bondage tape to block out her vision and restrict her movement and her skin was coated with Lidocaine cream (local anaesthetic). She was given a walking cane to sense her world with (as suggested by Dr Inman Harvey as being a close analogue for the robot’s sonar). In the performance the robot attempted to find the centre of the room using a control system evolved using a genetic algorithm and a single sonar sensor, Dumitriu attempted to find the centre of the room using her remaining sensory capacity and a counted the paces she took to get from one side to the other. The robot method is faster in this case and the Dumitriu’s very human approach is a demonstration of the incommensurability between artificial and biological life but nevertheless the work demonstrates clearly just how different ‘machine consciousness’ might be. These ideas were also brought out in digital projections to accompany the performance created artist Alex May.

Taking on the role of a robot agent is not a trivial process. The idea that a robot phenomenology is something that we could access is a contentious and flawed idea, however, an attempt to mimic the phenomenological experience of a robot should be of interest. The possibility of impoverishing the artist’s sensory experience to that of a robot is not achievable and neither is the idea of an artist replicating the functionality of a wheeled robot through her own physicality. However the ongoing performative experiments reveal to both the wider public and to invited scientists and philosophers many of the issues inherent in developing machine consciousness, potentially revealing new insights whilst acting as a form of public engagement in robotics research.

In her experiments Dumitriu has attempted to enact “robot experience” with particular focus on Francisco Varela’s work on how a robot might be considered to “mindfully” interact with the environment in which it is embedded. It focuses only on the sensor data it can receive and react to and not concerned with the floods of thoughts and emotions that fill (and pollute?) our human minds.

The practical aspects of the project are important to Dumitriu’s understanding and Dumitriu built the robot agent from scratch in collaboration with a robotics specialist. The wheeled robot has the capacity to take in a large number of sensory inputs but currently is just using sonar. It is important for the work that Dumitriu understands fully how the robot is constructed in order to deconstruct it psychologically for the audience.

The work done in the Emergence of Consciousness project is now being built on in Dumitriu’s new collaboration with the University of Hertfordshire where she and fellow artist collaborator Alex May have been appointed as Visiting Research Fellows: Artists in Residence in The Adaptive Systems Group (since January 2011). They are now working closely with Professor Kerstin Dautenhahn and Dr Mick Walters to develop a series of speculative robot heads designed to provoke the audience to think about their feelings about the possibilities of living with robot companions. It asks the audience to consider the field of social robotics and what they actually want in robot companions; how they should look, move and whether they should appear to be humanlike or ‘minded’. The first of these heads was exhibited at the Science Gallery in Dublin (April-June 2011) as part of their exhibition “HUMAN+ *The future of the*

species” and included a humanoid robot body built by the University of Hertfordshire with a head created using rear projection 3D video mapping and a hacked Microsoft Kinect that is able to take on the appearance of anyone looking at it (in group situations it creates a composite based on proximity). The idea is that users may prefer a familiar face but the work plays with the sense of the uncanny as users begin to recognise themselves (a disjuncture perhaps between the sensation that something is minded and the knowledge that it is not). The title of that head is “Familiar” and also references the idea of the ‘witches familiar’ (in mythology this is often a black cat), a creature which ‘appears only at a time of need’, ‘can act on the witch’s behalf’ and ‘can change shape’. Technology as witchcraft?

UNNECESSARY RESEARCH, WHAT'S THE POINT?

Anna Dumitriu

This panel outlines “The Institute of Unnecessary Research”(IUR) and presents a new paradigm in the way artists are engaging with the world through transdisciplinary practices. It brings together art, science and philosophy by creating participatory audience experiences. Sometimes humorous and sometimes grotesque, our work pushes boundaries and critically questions the means of knowledge production in the 21st Century.

Artists are innovators, if a new piece of technology or a new medium, becomes available; artists want to try it, to experiment with it- from microbiology to robotics; from tissue culture to neuroscience. Some artists take on the role of a scientist in almost a performative way and some scientists become artists themselves. Philosophy and ethics is always at its core and the work unpacks the instrumentalization of science and art for commercial and political ends.

Forms of “connective aesthetics” (Gablik) are used to engage audiences in participatory experiences that extend and generate new outcomes through exhibitions and events going beyond simple interactivity, throwing authorship into question, as members of the audience are inspired to become Unnecessary Researchers in their own rights.

The IUR was founded in 2005 by Artist Anna Dumitriu following discussions at the “Rules of Engagement” Conference on the nature of Art and Science collaboration, held at York University, UK and organized by Arts Council England. The original ‘blue sky’ vision for the IUR was a major research facility where scientists were employed to work with artists, thereby avoiding the common situation of scientists’ lack of availability/time when engaged in art/science collaborative projects. Scientists tend to view a collaborative art/science project as extra-curricular to their ‘day jobs’, whereas to an artist the collaboration is often key to their ‘day jobs’ in terms of being either a grant funded project, commissioned piece

or artists' residency. This inconsistency is one of the biggest hurdles for art/science collaboration to overcome, often far greater than issues, such as funding, audience engagement and linguistic incommensurability. Key to the notion of art/science collaboration are these reoccurring questions, "What is the purpose of it?" "What can an artist offer to science", "In terms of art, why engage with science at all?" "What levels of cross-fertilization should happen" and most importantly "what has art got to do with knowledge anyway?" The IUR attempts to work with these questions.

There are obvious financial issues with building a major research facility for artists to work with scientists (the IUR favours a underground facility carved out of a rocky island that can only be reached by boat or helicopter (for purely aesthetic reasons)) so it was decided that The IUR should initially be started as a hub for artists or scientists working a high levels of trans-disciplinary practice, strongly concerned with the philosophical implications of their methodologies, interested in public engagement and practicing in ways that could be described as 'performative' in nature. A web site was set up in 2005 and a very low-key performance event took place in Dumitriu's studio above The Phoenix Gallery in Brighton, England. Since then the has project attracted wide interest and has grown form there, including further performances and interventions at Sussex University, The Whitechapel Gallery in London, ETH in Zurich and as part of many festivals.

The Institute of Unnecessary Research is now an international hub for researchers and artists working experimentally and deeply engaged with their specific research areas. We present our research through performative and experiential methods, engaging the public and new audiences in our ideas.

The IUR uses performance as a means of conveying research; often events have an interactive component, the audience taking part in experiments and research activities thus changing the direction, development and final outcomes of the artwork. Critical theorist Suzi Gablik discusses in her essay on "Connective Aesthetics" that the traditional relationship of the artist to the artwork has come to be superseded, and that this social role of art has become increasingly important, since there is:

".. a rejection of modernism's bogus ideology of neutrality. Many artists now refuse the notion of a completely narcissistic exhibition practice as the desirable goal for art". (Gablik)

Artists have now come to see the process as equal to, or even more important than the outcome, or the performance is more important than the documentation of it. So the means of production of the artwork as a dialogical and collaborative process is also the outcome of the artwork in this model, which is what makes it so relevant to Art/Science practice, it is an analogue of the typical, natural relationship of the artist to the scientist (and vice versa), the journey rather than the destination. Although not inherent in all Art/Science practice it would seem logical to include the audience in the collaboration, with their own vast tracts of knowledge and experience. Gablik states:

"..there is distinct shift in the locus of creativity from the autonomous, self contained individual to a new dialogical structure that frequently is not the product of a single individual but the result of a collaborative and interdependent process". (Gablik)

This influence of performative, dialogical aesthetics, which comes from the collaborative structure of Art/Science practice makes it a useful technique for reaching out to new audiences in a non-hierarchical way. But these forms of collaboration are not easy and require huge conviction, and effort from all partners involved.

The IUR mimics and subverts the Institutional model it is based on. There are various 'departments' each 'headed' by an unnecessary researcher. The 'department' names are created by the individual artists, scientists and philosophers and based on their personal research areas. When a researcher joins they come up with a 'department' name, if they leave (and the IUR is a dynamic group in this sense) it is likely that the 'department' is discontinued (at least for a while)

For instance the Head of Crockery resigned his role (from within the online cyber world Second Life in 2006), as part of a multimedia performance at Sussex University, the position of Head of Crockery currently remains unfilled.

There is no official selection procedure for department heads, unsolicited enquiries are responded to with a warning that selection procedures "are entirely nepotistic", in fact the IUR grows organically through increasing networks of international contacts. Current departments include: 'Projective Geometry' (Alex May), 'The Digital Simulacra' (Luke Robert Mason), 'Neuroplastic Arts' (Gordana Novakovic), 'Textile Abuse' (Bettina Shuelke) and 'Viral Contagion' (Tagny Duff). There are currently 25 departments across distributed locations and the project is directed and co-ordinated by Anna Dumitriu (whilst working on her own research interests which cross microbiology, artificial life, robotics and ethics).

The name "The Institute of Unnecessary Research" is, in many ways, confrontational. It raises the question what is necessary research? Unnecessary does not imply pointless, it often means going beyond the normal (in the Kuhnian sense of 'normal science') and crossing boundaries, asking where do we draw the line with what we study or with what can be studied? Unnecessary Research encourages eccentric, obsessive, creative working practices and is an antidote to the stranglehold placed on research by central government and the gatekeepers of academia.

COLOURBLIND: MACHINE IMAGINATION, CLOSED EYE HALLUCINATION AND THE GANZFELD EFFECT

Alan Dunning & Paul Woodrow

The Einstein's Brain Project is a group of scientists and artists working together to develop installations and environments exploring ideas about consciousness and the new constructions of the body. Recent work has used strategies taken from paranormal science and psychology to explore how interpretation in shared machine-human environments contributes to the construction of our worlds.

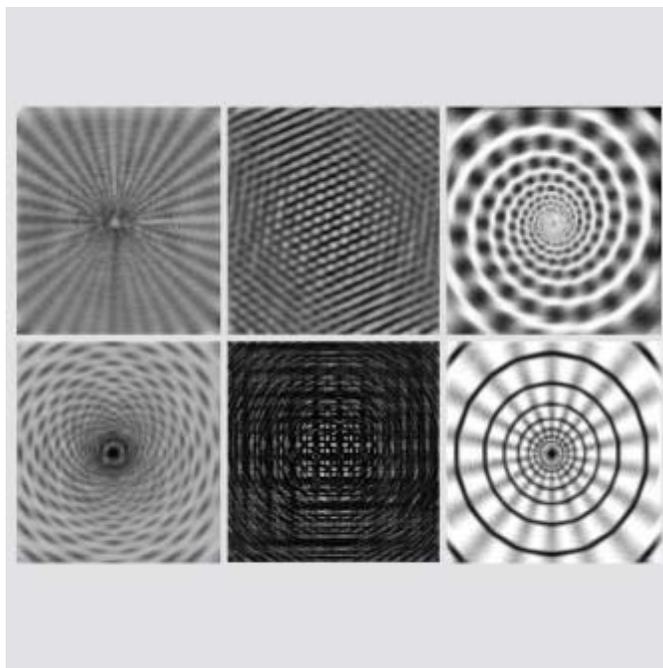

Fig 3. Typical patterns seen in CEH, © Alan Dunning

This paper introduces and contextualizes a series of new works – ColourBlind - that explores the internal workings of a machine through an implementation of the Ganzfeld Effect and Closed Eye Visualisation insofar as they relate to ideas about hallucinations in human and machine hybrids. The work explores ideas about machine vision and how hybrid interpretation gives rise to unbidden and unexpected colours, images and patterns in streams of unstructured data, and how undifferentiated monochrome colour can affect interpretation imagination. Through an examination and analysis of visual system noise expressed as spatial temporal voxel volumes, the work explores these investigations as machinic hallucinations.

The Project's work is focused on how new representations of the body can conflate the virtual, symbolic and imaginary through the use of interactive performances, environments and installations that promote a high degree of disorientation and an awareness of the moment to moment construction of a self. Recent work has developed generative systems in order to reference ideas inherent in EVP (Electronic Voice Phenomenon) to examine ways in which we construct worlds, and bodies in worlds, through pareidolia - the psychological phenomenon involving a vague and random stimulus - often an image or sound - being perceived as significant, and apophenia - the seeing of connections where there are none.

This work has used, amongst other strategies, face tracking and feature recognition, to explore the felt presence of absent bodies, using intelligent symbiotic systems, comprising both machine and human vision and analysis, to reveal patterns – the shapes of faces, the sounds of voices - in apparently random visual and audio noise. These works explored the construction of a world delineated by presence and absence, and pattern and randomness, locating the body through a construction that is both machine and human.

In recent times the development and dissemination of computer generated imagery has made commonplace constructed visual spaces that are fundamentally different from the mimetic and naturalistic representations of traditional media like painting, photography and film. But it is the increasing prevalence of machine and computer vision, and seeing machines, which has produced the most radical shift in the manner in which the world is perceived and constructed. This habitual employment of technological devices and programs has reconfigured both our conceptual and perceptual frameworks to the extent that what might be called natural vision is beginning to be superseded by machine vision. This suggests that vision is becoming disengaged from human needs and is now transferred to a technological plane.

The Project's exploration of hybrid perception and interpretation in shared machine-human environments concentrates on the idea that any visualization is a complex manifestation and indication of internalized machinic activity. In previous work we have been forced to acknowledge that our visualizations are constructs that are not uniquely related to the information that generates them. They are a complex hybrid of machine analysis, human interpretation, and scientific and artistic vision, which promotes a remapping of information beyond its immediate functional value. The drive to fill in the spaces opened up by those parts of an entity that resist their informational links, produces what we might only think of as false positives, but in doing so brings into focus acts of cognition that are inextricably linked to the building of meaning, the understanding of narrative, and, in turn, to the techno-subjective restructuring of the body.

The Ganzfeld (complete or open field) effect [1] is a phenomenon of visual perception caused by staring at an undifferentiated and uniform monochrome field of color. Usually this is accomplished by the subject wearing tight fitting goggles that block out all but one colour of the spectrum. In the 1930s psychologist Wolfgang Metzger, investigating gestalt theory, established that when subjects gazed into a featureless colour field they were unable to see anything after even a few seconds. In further experiments subjects that are immersed in the monochrome field for extended periods of time consistently hallucinated and recorded distinct EEG patterns of activity.

It is a well-known phenomenon with historical precedents in the followers of Pythagoras entering dark caves to gain wisdom through visions, [2] and in reports of trapped miners hallucinating and seeing ghosts. Similar experiences are often cited by Arctic and Antarctic explorers who report altered states of mind while traveling across large featureless landscapes. It is thought that the hallucinations in extended Ganzfeld experiments are the result of the brain amplifying neural noise in order to look for the missing visual signals, and it is this noise that is interpreted in the higher visual cortex, giving rise to hallucinations.

A ganzfeld experiment is a technique used in the field of parapsychology to test individuals for extrasensory perception. In the context of ColourBlind its similarity to scrying – an ancient system of revelation through prolonged observation of an object - should be noted. Martin Howse's experiments in scrying, in so far as they relate to our electronic environment and the revelation of a hidden city [3] have a particular resonance, as does Friedrich Kittler's exposition on the electro-mysticism of Thomas Pynchon's novels. [4]

In Closed Eye Hallucination an individual sees blobs, colours in motion and sometimes objects, even though the eyes are closed. Closely linked to the experiences of subjects in Ganzfeld experiments there are often patterns discovered within the blobs – most cited are webs, grids, honeycombs and other geometric and repeating structures. CEH experiences can take a number of forms: visual noise - seemingly

random noise of pointilistic light/dark regions with no apparent shape or order; light/dark flashes - regions of intense black or bright white that appear in the noise; patterns – highly organized motion and color forming complex geometric patterns and shapes; and finally objects and things.

In the ColourBlind works a camera is turned on, and covered with a single Ganzfeld goggle [5] and bathed in a pure yellow light. The only light passing to reach the camera's CCD is yellow light of 570 nm. The video stream is sent to a computer where the input is cropped and adjusted for fall-off at the edges of the camera so that the monochrome colour field is undifferentiated by tone or hue. The camera image is processed in Max/MSP to construct a voxel volume that is analysed for optical features within a specified region of interest. Tiny inconsistencies in the colour field, invisible to the human eye, false positives if you will, are tracked as they pass across 3 planes in the x, y and z dimensions of the volume. These inconsistencies are amplified and rendered as pixels on a video plane that becomes increasingly densely populated through additive blending. These pixels are streamed to a projection on the wall. Over time patterns gradually emerge as the video frames are accumulated and multiplied together. Two other screens show in turn the light that is seen by the camera and the voxel volume of data passing across the analyzing planes.

What starts as pure noise gradually resolves itself into patterns with structure and form. Sometimes these form rapidly, but usually these are the results of layers of noise blended together over long periods of time. The patterns that emerge bear a striking resemblance to patterns that are normally associated with those seen in closed eye hallucination and Ganzfeld effect experiments in which subjects stare at monochrome uniform fields of colour.

The inconsistencies in the field come from the image sensor itself, in part thermal noise, and in part amplified background electrical noise that is present in the system, but the work suggest some other possibilities. The installation is a generative, closed system. An algorithm looks for any disruption on a uniform field of colour, which is stacked additively on previous instances of disruption. Over time there are many, many instances of the tiniest of ruptures in the visual field that together begin to organize the previously vacant colour field. These patterns are nothing more than the chance interactions and collisions of one another, but our interpretation of them hint at an analytic that forms in the interstice between machine and body within pattern and information flows, as the brain's xenophobic response to absence and randomness.

Earlier work used ideas found in *Electronic Voice* and *Video Phenomena* to explore ideas about presence and absence, and pattern and randomness. Installations took the form of blinded cameras that sent visual and audio noise to a computer that analysed it for patterns that looked like human faces and sounded like human speech.

In these installations the computer did the hard work of analyzing complex data, but the task of meaning making was left to the observer. Algorithms that found faces or human speech in the data stream found many barely meeting the requirements. The interpretation of noisy pixels as faces, or noise as speech was left to the observer.

On occasion these faces and voices were utterly convincing. They were, to all intents and purposes, real faces, real voices. They were not images of people, but another kind of image loaded with meaning, which arose accidentally, but irresistibly, from the hybrid interaction between machine and body. To all intents and purposes when these patches of pixels looked like faces, they were images of faces.

The faces and voices that emerged from the random flickerings in a machine hinted at an immaterial hybrid body that existed in the pattern and information flows that were fusion of body and machine, suggesting that there might be real information contained within the random noise of the work. Later work extended these ideas by organising noise and its visual equivalents as spatio-temporal volumes to enmesh an observer in a stack of noise slices, delivered by directional speakers. These works used pattern recognition algorithms to identify unusual repetitions, noticeable clusters, loops and so on, in concert with a moving observer who gave form to shapes and sounds. It is this work that informs the recent exploration of pattern emerging from a monochrome colour field sampled across time.

The very latest work draws upon current neurological research that acknowledges visual perception as a form of symbolic interaction in which information is gathered by the brain, but which bears no physical resemblance to the objects, and events of perception. According to VS Ramachandran, ‘...the brain creates symbolic description. It does not recreate the original image, but represents the various features and aspects of the image in totally new terms. “This activity is manifest in encapsulating behaviors and inferences, such as change blindness, selective attention, energy measurement, imagination and hallucination, in the construction of an image. The work uses images and sound conjured by machines in response to missing or incomplete information. Using the interpolation present in all media spaces to build imaginary presence, the work creates forms out of incomplete data drawn from cameras and microphones. The work looks at the possibility and consequences of invented images arising out of the discrepant and unstable representations that form our media constructed and electronically surveilled world. False positives, false bodies, false entities inhabit our media spaces, not only changing our inhabited world, but also our bodies and our being in the world.

In the work series *Doppelgänger* (2011), in which interlaced image fields are separated and re-interpolated again and again until only the interpolations remain, it is possible to see how images constructed in media spaces must unavoidably generate presence from absence and how this happens through a symbiotic relationship between machine and human, suggesting in the end that there are unseen, unstable representations generated within the medium itself. *Doppelgänger* creates a copy of an original made up of entirely machine–imagined data. Looking like degraded images of dolls or action figures, or twins, or Jekylls and Hydes, or merely sadder or happier version of themselves the duplicates are built on the digital DNA of the original, but have moved away from a stable state, reinvented by a machinic, algorithmic dreaming to take on a life of their own. The brain/body interpolates the absent information, filling in the missing gaps. It is possible to characterize images as contingent unstable, entropic zones. Even as the viewing subject assumes that what is viewed is a stable phenomenon, on closer inspection the image is an entropic event which is always receding, riddled with micro-discrepancies that play an important role in the construction of a world.

The work explores how images are constructed in media spaces, how absence is uniquely and unavoidably attached to presence, and how this is manifest through the symbiotic relationship between human and machine. Using the model of the *Doppelgänger*—a tangible double or look–a–like, or an image of oneself possibly glimpsed on the periphery of vision, new forms, looking or sounding like someone or something, but having no index in the real world, are constructed by machines in response to incomplete data gathered by cameras and microphones.

All of the Project’s pattern recognition work has much in common with the psychic spectres of Abraham and Torok, [6] Jonathon Crary’s bodies, [7] and with recent explorations into sonic hauntology, [8] par-

ticularly in its investigation into changing ideas about what constitutes authenticity, and with earlier explorations into EVP, [9] but its lasting impact is to acknowledge an ontological anxiety that imagines a body so enmeshed with its surroundings and the technologies that support it, that it becomes indistinguishable from the mechanisms of its representation and disappearance.

Increasingly our machines see and discriminate much as we do, and in turn change our perception of the world. *ColourBlind* explores ideas about how machines and we see and experience the world, and raises questions about the capacity to discriminate between what is important and what is not. In the search for pattern in randomness, for colour where there is none, when faced with the horror vacui of sensory deprivation the brain, and in this case the machine, continues its processing regardless, creating its own colours and forms as interpretative hallucinations.

CTRL – O CONFRONTING BARRIERS TO COMMUNICATION IN INTERDISCIPLINARY PROJECTS

Linda Duvall

Artist Linda Duvall was invited by the University of Saskatchewan to curate an exhibition of student research addressing digital media. The curatorial process revealed much about the gaps between disciplines. From the beginning, Duvall noticed that each area had its own specialized and idiosyncratic language. Even more instructive were the conventions utilized by the various areas for communicating information.

Fig 2 and 3. Viewer in front of painting and video installation by Art and Art History graduate student Michael Farnan in CTRL – O exhibition. Copyright Linda Duvall & Michael Farnan.

Introduction

'Interdisciplinarity' is a term that had a wave of popularity in the 70s in selected academic institutions around the world. Today, it is enjoying a revival – as evidenced by this conference – but there are major problems with inserting interdisciplinary programs into discipline-based institutions. I am proposing a working model, based both on my own art practice and an exhibition that I recently curated. The model that I am proposing both values and utilizes the expertise of specialists; and allows for people outside specialized disciplines to access specialized information. I tentatively call it 'snatch and grab.'

As a Visual Artist and Academic Fellow at University of Saskatchewan, I was invited by the university's Interdisciplinary Centre for Culture and Creativity to curate an exhibition that highlighted the range of research being undertaken by undergraduate and graduate students across the Arts and Sciences programs. The intent was to show some of the research and art projects that have looked critically at the role of digital media in culture, as well as to initiate a dialog among these students and the faculty that support them.

Project *Tea and Gossip*

Before I talk directly about this exhibition, and the implications for the students, the university, and the community, I will first position myself and the structures I have developed in my own art practice.

Although I define myself primarily as a visual artist, I have always considered that I work across a few disciplines. I have degrees in English and Sociology, Education, and two Visual Art degrees. As a Visual Artist, I have worked collaboratively with people from other disciplines and much of my visual practice embodies significant aspects of sociological research. This blurring of boundaries is a crucial part of my practice. I will show one example of a project that incorporates such research into my art practice.

My starting point for the project *Tea and Gossip* [1] was a personal story of misattributed paternity. In the short narrative video that I developed, the main character did not reveal the identity of the biological father of her daughter to her husband, her daughter or the biological father, until her daughter met and started dating her half brother.

I began by showing this video to friends and neighbours; and taping their responses. I purposely began by asking a diverse combination of people, from mediaevalists to street involved youth. As I continued, I noticed that many comments took an ethical direction; so I worked with theologians from evangelical Baptists to the other extreme. I also involved people who might offer legal, psychological, or medical expertise.

In the presentation of this work, I incorporated these diverse opinions and enabled visitors to further contribute their views, both verbally during the 'gossip' sessions and on small cards. In this instance, some people's contributions evidenced their disciplinary expertise, while others approached the questions from a more personal perspective.

So, when I was invited to curate a show that crossed many disciplines, I was delighted.

Exhibition *CTRL – O*

Now about the exhibition *CTRL – O*, the title referencing the keyboard shortcut for "open file." This show presented students who were paying attention to the possibilities of new global networks and innovative intersections of the fine arts, humanities, sciences and computer sciences. These projects included analyses of social networking sites, use of new media in community building or teaching, computer modeling and simulations, and technically complicated digital manipulations such as 3D and digital collages.

From the beginning, I noticed that each area had its own specialized and idiosyncratic language. Even more instructive were the conventions utilized by the various areas for communicating information.

In areas such as Sociology and English the students included as much textual information as possible under titles such as goals, objectives, and checklists. The visual elements were clearly secondary and proposed learning was through reading the compiled information.

The Computer Science and Science students presented projects that included participatory elements such as buttons or models. Here, the learning emerged through interacting with the material presented.

The Visual Art students presented material that contained no clear conclusions, but embedded elusive personal questions. Their viewers were left to draw their own conclusions.

Context for *CTRL - O*

Now about the context for this project: the exhibition was presented in a student art gallery as part of a university wide Technology Week and was widely advertised by the institution. The opening was held on an afternoon during Technology Week, during which each student made a brief presentation about his

or her work. Then there was time for visitors to meet with the students, and for the students to meet each other. The exhibition remained up for a week.

The University of Saskatchewan has recently introduced a new Interdisciplinary Program, called the Interdisciplinary Centre for Culture and Creativity, which initiated *CTRL-O*. However, since it is a recent development, there were only two students from that Centre who were part of the exhibition. The rest were all from defined disciplines within Arts and Science. One of the main aims was to initiate dialog across disciplines.

Assessment of *CTRL - O*

It is difficult to assess whether any of the defined aims of this project were met. The students remained firmly in their own disciplines, with their means of communication clearly modeled by the departments within which they studied. However, I did a follow-up survey in which I asked the students involved about any consequences of their participation in *CTRL-O*. Several reported that other disciplines had invited them to speak.

For example one art student wrote:

After the show, Prof M. asked me to talk to his class for a bit, then I invited some of his students back to the DRC to further look at the 3D modeling [...] The show really drove home that there are more cross applications of technology out there than we know.

None had begun to work directly with other students or other disciplines and none reported that there was a mutual exchange of ideas. Rather, any interchange had taken the form of an interested person with an already developed area of research wanting to get information from the student. This is what I call the 'snatch and grab' model.

As another example, I received this email recently from a community artist:

The show you curated at the Snelgrove has directly inspired my latest sculptural work. I contacted a few of the students in the show and met with them to discuss *my idea*. Cory S. worked on a prototype drawing for me which was used as the starting point for a CAD drawing and small maquette *produced for me* by the Engineering Workshop at the U of S. [Author's emphasis.]

This is a clear example of a community artist who engaged the expertise of the students in the exhibition for her personal project.

What was also interesting about this email was that it demonstrates the fact that this exhibition provided an opportunity for members of the Saskatoon community to see what was happening at the university. It seems that community members not involved in the university – as well as faculty and students in other disciplines – have difficulty finding out about academic research. This show provided a window into the area of digital media at the University of Saskatchewan.

Further Thoughts on *Tea and Gossip*

Looking at my own project *Tea and Gossip*, I realize that I also used the 'snatch and grab' model. I began with a defined structure in place. Each participant contributed their opinions and ideas based on their personal frameworks and expertise, and inserted these into my project. They each changed the content of a project a bit, but I maintained the framework through which visitors would access the material.

Conclusions

In conclusion, I would like to make the following comments and recommendations:

1. The model of 'snatch and grab' should not be seen as a failure of an interdisciplinary program, but rather an appropriate way to transfer information. One is ensured that the person initiating the contact is receptive, since they can already see an application in their own research.
2. There is a need for a full exploration of alternative models for the transmission of research material and interesting ideas. For example the Perimeter Institute in Waterloo, Canada has wide corridors with blackboards and coffee alcoves and lounges that are conducive to making visible one's current thoughts.
3. In order to have a 'snatch and grab' model work well in a community or an institution, one needs a context in which a range of researchers/faculty/students/independent scholars/children/elders show their work/ideas outside their defined disciplines.
4. Within the academic system, one needs a way to value the 'consultants' – those who find time within their own research to contribute to the understanding of others from other areas.

In conclusion, the current institutional structures are not conducive to a total blurring of boundaries, but there are ways to open up the discourse a bit, and to nibble away at the tightness of the disciplinary framework. The exhibition *CTRL-O* is one example of an approach; and the strategy utilized to develop *Tea and Gossip* is another implementation of that model.

STUDIO PEDAGOGY FOR SITUATED LEARNING IN THE CULTURESCAPE

VINCE DZIEKAN

This paper presents insights gained from developing studio pedagogy for situated learning in relation to the *Culturescape* study abroad program, which has been conducted for students of the Faculty of Art & Design at the Monash University Centre in Prato, Italy on an annual basis since 2009.

Culturescape's meta-learning contexts, Diagram. © Vince Dziekan.

1. Introduction

The *Culturescape* program has been conducted for students from the Faculty of Art and Design at Monash University in Melbourne on an annual basis since 2009. This study abroad program is undertaken as an intensive and immersive studio residency over a five-week period at the university's international center in Prato, Italy. The curricular orientation of the course has been designed with a focus on exposing undergraduate Art and Design students to independent practice through introducing them to the potentials for creating communication experiences that combine site-specific, location-based practices with digital image-making and creative technology. During their studio residency, participants are given the unique opportunity to develop individual and collaborative projects that respond creatively to their experiences of place, space and community.

2. Institutional Context

2.1 MONASH ART AND DESIGN

Monash Art and Design is an integrative center for socially engaged research and teaching, with a commitment to the creative enrichment and physical and cultural sustainability of our communities through visual art, design and architecture. Established in 1998 as part of Monash University, one of Australia's

Group of Eight research-intensive universities, the faculty is the university's authority in the area of visual culture.

As a collegiate community, academic staff are committed to studio teaching and research that reflects the diversity of approaches found in contemporary visual culture and the design of the built environment. While such a 'teaching/research nexus' develops from an understanding of the basis of disciplinary practices and applicable research methodologies to their fields of inquiry, the ability to foster an attitude towards the larger subject of 'practice-based research' in Art and Design is supported by the capacity to apply these forms of knowledge, both conceptually and in practice, towards collaborative and transdisciplinary contexts.

2.2 MONASH UNIVERSITY CENTRE, PRATO

Internationalization is an important catalyst for both education and research across Monash. Over the past decade, Monash Art and Design has conducted a regular series of study abroad programs at the university's key physical presence in Europe: the Monash University Prato Centre.

Located within easy proximity of Florence, the center itself occupies the Palazzo Vaj in the historic *Centro Storico* of the medieval walled city of Prato, which established itself prior to the Renaissance as an important civic and economic center, particularly in respect to the textile trade. Subsequently, the town became a leading industrial center in the nineteenth century, with Italian historian Emanuele Repetti describing it as the "Italian Manchester." As a by-product of trade and industrialization, Prato has experienced significant social repercussions from both internal and external migration. Today, the city has one of the largest Chinese immigrant populations in Italy, second only to Milan. [1] Prato, thus, provides a unique base for conducting intensive studios where Art and Design students are encouraged to respond to their cross-cultural experience of the paradoxes that abound in globalized contemporary society, while being exposed to the dominant cultural legacy of the West: the Italian Renaissance.

3. Contexts for Meta-Learning

3.1 OVERVIEW

This remainder of this short commentary article will broach some of the background and contextual considerations that inform *Culturescape's* educational approach to developing a studio pedagogy that engages with situated learning in relation to emerging creative technologies. The text will provide a general overview of how the course structure has been designed in response to its institutional and 'meta-learning' contexts by offering a series of provisional observations that reflect upon the course's pedagogical structure, project design and student experience.

According to Jean Lave and Etienne Wenger [2], 'situated learning' acknowledges how the process of knowledge is co-constructed, occurs in context and embedded within a particular social environment. Theoretically, situated learning stands in contrast to most conventional forms of teaching and learning activity where the 'knowledge' (and 'know how') is largely abstracted by being encountered out of context. Through the integration of fieldwork in and around Tuscany, complemented by active studio engagement and critique, students are provided with an expanded studio experience. This composite 'learning environment' combines a curricular structure designed to interrelate with its cultural setting

and social situation enabling them to explore their studio practices through designing creative content for emerging art and design practices, including a particular focus on 'geo-cinema' – which according to artist Pete Gomes is “the new cinema of commuting; variable and embedded in motion, locations, and fluidity.” [3]

In an educative sense, 'meta-learning' places an onus on how the learner's understanding of the learning context and the phenomenon of learning *itself* contributes towards gaining subject-specific knowledge. Described as the process by which learners become increasingly aware of habits of perception, inquiry and learning that have been otherwise internalized, [4] the concept of meta-learning emphasizes the central importance of independence to the subject of study and, more specifically, to the roles that inquiry and reflective thinking play in learning contexts. In particular, self-identity and self-development provide an important connection to the 'ontological dimension' that characterizes the nature of art and design learning where “the development of knowledge, practical skills, cognition and technical expertise, are closely interwoven with the development of feeling, perception, confidence, sense of purpose and identity, and a tangible enrichment of lived experience.” [5] In order to develop their skills in greater self-reliance, students are required to engage in meta-cognitive activities that develop awareness of both their conceptions of the subject of study and of themselves as learners in learning contexts that are comprised of “a complex array of interrelated factors.” [6] [Fig.1] As succinctly encapsulated by Tara Winters: “Meta-learning is often associated with ideas of self-regulation, self-motivation, self-reflection and independence as a learner, making it a concept of particular interest to art and design educators.” [7]

3.1.1 DISCIPLINARY (SUBJECT) CONTEXT

While available for any student in the faculty, the curriculum design of the *Culturescape* program is best suited for students situated in the middle stage of their tertiary studies in design-based disciplines in Visual Communication, Multimedia and Digital Arts; and Fine Arts students specializing in photo-based contemporary art practice. The integrated program draws upon an existing suite of units, that when so combined, support the multidisciplinary study of new media design and contemporary image arts. Briefly, the unit offerings that are made available to participants as part of *Culturescape's* integrated program include:

Digital Imaging studies in *Digital imaging* and *Digital Imaging Studio*

Digital Imaging focuses upon creative image production for a range of digital media applications. In this unit, students explore the creation, manipulation, composition and output of digital images with increasing conceptual understanding of representational issues, visual language and communication. For its part, *Digital Imaging Studio* is designed to offer students with the opportunity for self-initiated investigation of imaging approaches and digital media specialization specific to their proposed projects.

Photomedia studies in *Photomedia Fabrication* and *Photomedia Virtual Studio*

Photomedia Fabrication builds upon the skills and knowledge of photography by focusing upon creative image production through 'fabricated' photographic approaches that develop their understanding and application of lens-based photography by exploring the construction of photographic reality. Meanwhile, *Photomedia Virtual Studio* promotes the development of creative skills through a combination of analog and digital techniques, exploring lens-based and soft-imaging for print and screen-based output.

3.1.2 STUDY ABROAD (SOCIO-CULTURAL) CONTEXT

The course delivery is structured around an intensive five-week study program. In addition to attending formal studio teaching blocks, there is the associated expectation that students will thoroughly engage in independent study (both in and out of studio, through personal fieldwork and site visits) to achieve expected coursework requirements.

The following standard format has been used to guide the weekly program delivery:

Mondays are dedicated to studio work involved with the collaborative production of the assigned directed project designed to directly engage with *Culturescape's* main emphasis on locative media and relational forms of communication design. Complementing the group activities that are a feature of Monday's studio, Tuesdays are dedicated to self-directed project work over the duration of their residency. Each participant is expected to propose and negotiate a major individual project, which will come to represent their study abroad experience. This approach affords the students with the opportunity to experience what it means to work as an 'artist-in-residence.'

Formal presentations and semi-formal seminars are held regularly on Wednesdays. The nature of these lectures evolves over the duration of the course, culminating with a forum where all participants present and report on their individual project outcomes. Wednesday afternoons are set aside for short, focused excursions to cultural sites and galleries in Florence or other locations within the region. Dedicated site visits are made to major cultural heritage sites, including the Duomo di Santa Maria de Fiore, the Uffizi Galleries and L'Accademia. Complementing the attention paid to Renaissance art, special onus is also placed on visiting contemporary exhibitions curated by the Centro di Cultura Contemporanea (CCC Srozzina) at the Palazzo Strozzi.

Perhaps surprisingly, significant contemporary exhibitions have also been presented in Prato itself, as well as its neighboring town, Pistoia. Last year the Commune di Prato hosted a multi-site project by Thomas Ruff that innovatively presented works by the German photographer within the institutional spaces of its civic offices. Palazzo Fabroni in Pistoia hosted the particularly relevant exhibition: *Viaggio in Italia*, which presented a wide cross-section of works inspired by encounters with Italian life, culture and landscape produced by leading contemporary artists ranging from Carsten Holler and Thomas Struth, to Carlos Garaicoa and Richard Wilson.

Given the wealth of places to experience that are within easy reach of Prato, Thursdays are used for conducting day-trips to Bologna, Sienna, Lucca and Pisa. While cultural tourism acts as the primary focus of visits to these major regional centers, in a large number of instances these experiences provided the impetus for ideas that would become fully distilled and articulated later in studio works. Finally, Fridays are treated as 'open studio' days for independent study or fieldwork.

The routine of this regular weekly schedule has been broken by the main annual excursion to Venice for the *Venice Biennale*. The opportunity to attend this leading international cultural event showcasing contemporary art (Daniel Birnbaum's *Making Worlds* in 2009) and architecture (Kazuyo Sejima's *People Meet in Architecture* in 2010) has proven to be particularly inspirational to the students and has made a significant impression on the subsequent development of numerous individual's self-directed studio projects.

3.1.3 STUDIO RESIDENCY (VISITING ARTIST) CONTEXT

As indicated previously, the visiting artist or artist-in-residence model offers a distinctive way of describing the studio context in which meta-learning takes place in *Culturescape*. The program's studio pedagogy is put into practice through two complementary, self-supporting projects: a collaborative, directed project and an individualized, self-initiated studio project. Given the limitations of this paper, I will only expand at this time upon pedagogical considerations associated with the directed project and how this brief was used to instill an underlying sense of situated learning, that, in turn, underpins the self-directed studio projects that would eventuate.

Collaborative, Directed Project

Upon commencement of the course, the students were presented with a directed project. This brief was employed as a means of challenging the participants to give form and meaning to their initial experience of Prato, its local vernaculars and environs. Importantly, the project was collaborative in nature and emphasized the forming of social relationships at the inception of the study abroad experience. The project was used as the principal focus of creative activities over the first half of the study abroad residency; this balance switched towards individualized, self-directed studio investigation following the excursion to Venice (which has effectively acted as the juncture between these respective projects).

Thematically, the directed projects run in both 2009 and 2010 have focused on the narrative potential of communicating mediated scenarios designed to be experienced directly in public space. The assignment encourages the students to conceive of a form of cross-media storytelling that draws upon the 'psycho-geographic' features of the local environment of Prato; Psychogeography being defined by Guy Debord in his 1955 *Introduction to a Critique of Urban Geography* as the study of "the precise laws and specific effects of the geographical environment, consciously organized or not, on the emotions and behavior of individuals." The spirit of this form of inquiry is used to draw from the student's immediate subjective response to finding themselves in an alien situation; drawing out from this the meta-cognitive subject of the exercise: a knowing, self-awareness of the multi-dimensional nature of their creative practice as situated in the roles of student, tourist, explorer, ethnographer, social commentator, filmmaker, etc.

On the occasion of CS2010, the following assignment brief was issued:

Quattro Bastioni

Prato is a classic example of a medieval walled city. Referring to the map of Prato, each group is assigned to one of the four main gates or 'bastioni' that acted as main 'command and control' points of the town in the middle ages, monitoring movement by regulating entry and exit of who and what was allowed in and let out. Connect each of these nodes with another by determining three intermediate locations along a walking route. At each designated location, a specifically assigned piece of media is to be played on a hand-held portable media device. Each group determines the narrative relationship between media content and where it is to be played in situ.

The studio project was supported by supplementary lecture content and studio exercises. An introductory lecture was presented in order to establish key precepts relating to site-specificity and digital technology; portable and distributed media. The historical legacy of site-specific installation (such as Walter

De Maria's *The Lightning Field* and Richard Serra's *Titled Arc*) as well as Nouveau Realisme (which proponent Pierre Restany described as "a poetic recycling of urban, industrial and advertising reality") and Situationism were overviewed in an effort to broaden the frame of reference that the students could bring to their creative development. The currency of situated practices was supported by illustrating the diversity of contemporary works by the likes of Kryztof Wodicko and Janet Cardiff, in addition to graffiti and other forms of cultural intervention in public space including pervasive gaming.

Complementing this content, an introductory creative exercise was instigated as an exploration of photographic reconnaissance and narrative structures. Following a shooting brief whereby the students were directed to conduct a one hour photographic reconnaissance of Prato, each student was issued with a series of design challenges as a way of applying a selection of their resulting images for narrative purposes. These focused on formal principles of juxtaposition, the relationship of image and text as well as storyboarding, while narrative voice was explored through forms of first and third person perspective and dialog.

4. Concluding Observations

Through the combined contexts provided by its expanded studio, *Culturescape* places an emphasis on participants engaging in meta-cognitive activity, thereby encouraging each student to become increasingly aware of their studio learning and the context of these processes in their institutional settings and situatedness in highly context-specific environments.

In summary:

By drawing upon the subject-specific features of photography and digital imaging, *Culturescape* emphasizes the role of communication design and new media arts in the creative conception and design of cross-platform communication experiences.

Culturescape operates as a flexible learning environment that places importance on processing 'field' experiences through studio practice. The resulting 'expanded studio' draws from the visiting artist or artist-in-residence model, thereby exposing the student to aspects of independent professional practice and practice-based research.

The curricular framework of *Culturescape* transitions from directed to self-directed projects. In order to do so, the pedagogical role of a 'geo-cinema' project is used to promote attentiveness to cultural specificity and the situated nature of studio learning experience.

1. According to available statistics, 10,000 legal Chinese residents were living in Prato in 2008; a figure significantly lower than the 45,000 estimated by local authorities taking into account illegal immigrants. First arriving in the early 1900s, the majority of Chinese work in businesses and workshops related directly to the garment industry. In 2010, raids on factories employing illegal labor highlighted the social and economic tensions that exist in the Pratese community.

DESIGNING A WAY TO VISUALIZE THE INVISIBLE THROUGH THE DYNAMIC ILLUSTRATION OF CONVERSATIONS

NATALIE EBENREUTER

This paper discusses the creation of a multi-modal data driven prototype application called the *Conversation Viewer*. Designed to visually represent the evolution of a conversation through a dynamic touch based graphical interface, it illustrates various elements of participants' email, text and voice messages as they seek to find a mutual agreement around a meeting date.

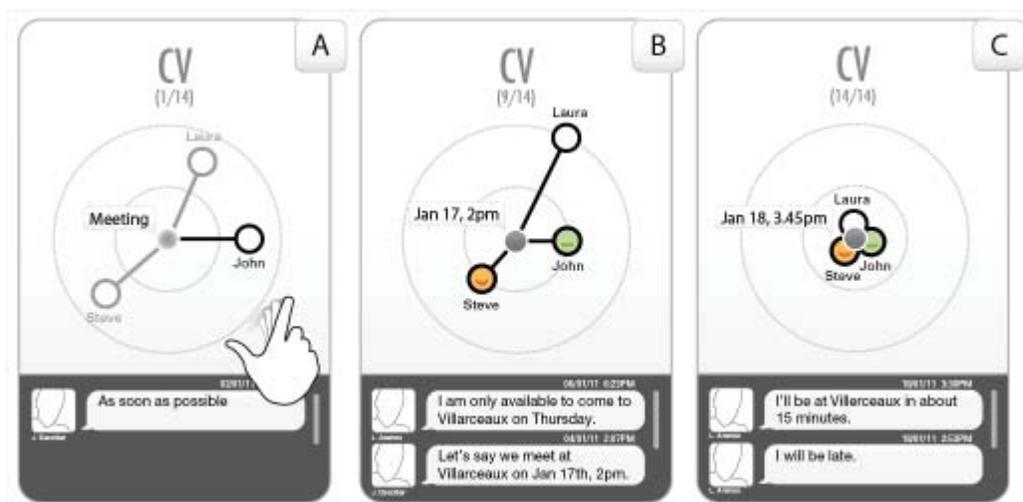

Fig. 2. Conversation Viewer: use case scenario, 2011, Natalie Ebenreuter, graphic media, Copyright Bell Labs France.

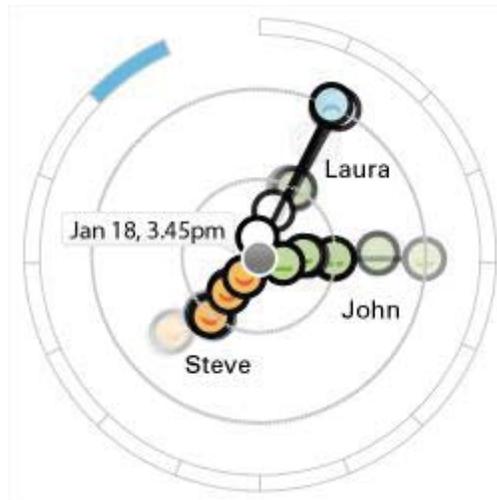

Fig. 3. Conversation Viewer: an historical narrative, 2011, Natalie Ebenreuter, graphic media, Copyright Bell Labs France.

Introduction

The rise of social media and the sophisticated development of third party applications, in combination with an ever-increasing range of mobile devices, makes the immediate communication of ideas between individuals, different communities of practice and the wider community possible. While we have the ability to send and receive vast amounts of information, status updates and social commentary about different events there is a need to capture dynamic systems of communication in a way that illustrates the less visible relations between participants of a conversation. This is significant to situations where the consequences of numerous interactions can change the perspective and direction of different courses of action. For example, this holds relevancy for participants in distributed environments involved in the collaborative development of long-term projects. Since digital communications commonly involve direct communication between individuals responsible for sending and receiving information, knowledge resulting from group discussions or informal corridor conversations is not as easily shared amongst participants in distributed environments via email, project documents and websites.

Rather than seeking to integrate multiple systems of communication made available through aggregation tools such as *Netvibes* [1] or *Hootsuite*, [2] this research focuses on assisting others to contextually build relations between their different communications. Here the intent is to supply individuals with a comprehensive understanding of the circumstances surrounding the progressive development of different thoughts and actions that lead to mutual agreements. This approach positions human participation, negotiation and understanding at the heart of dynamic communication systems and looks beyond the notion of interaction as the mere sending, receiving or aggregation of disparate messages. For the purposes of this research, the term 'dynamic situation' refers to a set of circumstances in which one has an awareness of their surrounding environment. In particular, this can be understood as a situation that enables individuals to understand not only their contribution to an ongoing conversation but also that of other participants involved in the same discussion.

In light of this, Bell Labs France researchers specializing in hybrid and social communication, intuitive collaboration and applications design worked together to develop a prototype application called

the *Conversation Viewer*. Its role is to make visible the abstract relations that exist between participants of a conversation. A touch-based graphical interface is used to interact with and visualize the progressive development of conversations drawn from participants' email, text and voice messages. The data driven prototype application was initially designed as an iPhone application that was later developed for the iPad (See Fig. 1).

The impact of functionality on form

The goal in designing and developing the *Conversation Viewer* was to create a way to deal with the often-fragmented experience of understanding individual and group intentions expressed by voice and text-based data. In doing so, the *Conversation Viewer* aims to provide greater awareness surrounding the overall actions and interactions of participants engaged in evolving conversations. This is where time as a factor of interaction in the past, present and future can be used not only as a reference to illustrate the history of a conversation but also to study the value of interactions.

The key function of the *Conversation Viewer* is in the utility it offers participants to interact and develop conversations. Interaction forms the basis of conversations in which elements of dynamic situations are negotiated between participants to develop a desirable outcome. The impact of functionality on the form of conversations is in the approach taken by participants during the course of interaction. It is important that understandings are not communicated; instead they are built collaboratively through conversation where participants derive meaning from their interpretation of a discussion. A new-formed understanding is then offered to participants for further interpretation and comparison to the original, which eventuates in mutual understanding and agreement. [3] In this way, it is possible to understand how the collaborative development of a dynamic situation facilitates the collective learning of different objectives between participants through a shared process of negotiation, understanding and agreement. Hence, the *Conversation Viewer* offers a means for individuals to inquire about the evolution of dynamic situations and exchange information through a series of interactions to reveal and resolve contradictory ideas.

Fundamental to this is the function of an observer as an accepted participant in the act of observing that allows for subsequent understanding from such actions to be derived. [4] During the development of interaction, individuals are accepted as mutual participants in the act of knowledge creation. In doing so different individuals, considered as observers and participants, become necessary elements in the development of dynamic situations. This in turn enables them to act subjectively. By interacting with various participants involved in conversation, understanding is created through the exchange of ideas that lead to mutual agreement. This involvement is interactive and productive so that individuals affect and are affected by the interactions in which they participate. The interaction should represent the culmination of the participant's interpretations. Significant to this is that, "The language of the conversation must bridge the logical gap between past and future, but in doing so it should not limit the variety of possible futures that are discussed nor should it force the choice of a future that is unfree." [5] This is important because the form of a system directly influences its usefulness as a tool to support the evolution and understanding of dynamic situations.

The useful and visible functions of a system

The expression of individual intentions and the broad circumstances associated with various events and actions that take place within dynamic situations underpins the useful function of the *Conversation*

Viewer. Creating a tool to achieve this becomes challenging, since there are no established interaction design patterns or use cases for the design of dynamic communication systems. Nor is it possible. The *Conversation Viewer*, therefore, seeks to provide end-users of the system with a contextual timeline of events that visually flow together with the collaborative evolution of conversations over time. Building the relations between these activities means that individuals communicating with and through the *Conversation Viewer* are not required to search through numerous email threads, text messages and voice mails to gain a quick overview of the current state of conversation. Instead, the data driven system illustrates conversations at both general and detailed levels of information in the form of a visual narrative. The 1MC Viewer also opens up the potential to express the character of individual actions or those of a group. To achieve this a technical component called a sentiment analyzer interprets the mood of an individual's communication and illustrates it in the design of the ambient interface. While applications such as the iPhone Tracker [6] provide a contextual and historical narrative of an individual's physical movements from location-based data captured by the iPhone, the *Conversation Viewer* represents a visual narrative of (1) participants' relationships towards reaching an agreement, (2) general and detailed information about the terms of agreement, as well as (3) the emotional disposition of participants during a conversation, as an organized integrated whole.

To give further context to the application's use, the following scenario briefly describes the potential interactions that could take place during the discussion, understanding and confirmation of an agreement. For the purposes of this example the terms of agreement are to find an appropriate meeting date. Fig. 2a represents the first interaction in a conversation. It illustrates a message from John in brief format that has been reduced in detail for the purposes of simplicity, as a function of the system. When touched, the message expands to show its detailed contents if so desired. At present, the agreement point is unclear, which will become more focused when a precise meeting date is proposed. Laura and Steve are represented in grey while John is represented in black, as he is the first to participate in the conversation. The participants of the conversation are positioned as neutral with respect to the agreement point. This is indicated by the background location rings in the design of the interface to help visualize each participant's relationship to the terms of agreement. As each participant of the conversation interacts with one another, their visual appearance transforms from grey to black. Simple emotions are also represented by the system's interface, based on semantic information found in each communication.

Halfway through the discussions in Fig. 2b a specific meeting date has been suggested. This is visually confirmed by the clarity of center point at the core of the agreement. Here both John and Steve are closer to the agreement due to their repositioning with respect to the location rings. We can also see that Steve is happy about this arrangement while John remains neutral to the current proposal. Finally, after much discussion the meeting is confirmed (see Fig. 2c). This is visually represented by the participants close proximity to the agreement point and its solid appearance. By presenting conversations in this way, it is envisaged that participants of the conversation can gain an understanding of their development more easily than reading or listening to each individual email and voice message that forms the basis of their representation. Furthermore, with the added functionality of (1) a global slider in a customized version of the *Conversation Viewer* shown in Fig. 3 or (2) the gestural activity of swiping along the vertical list of communications on the left hand side of the iPad application in Fig.1, an animated view of the conversation visually evolves at the same time each moment of the discussion is discovered.

Discussion

The overall purpose of the *Conversation Viewer* is to facilitate different ways of observing and participating in conversations and to offer end-users of the system greater contextual understanding of the evolution of dynamic situations. This is achieved through conversation where multiple viewpoints are expressed, visualized and internalized by those engaging in the discussion. As a result, a shared understanding of what is known from that which was previously unknown is created. Essential to this communication is that participants enter into the conversation with different perspectives and individual understandings that are distinct from any others. Given that without difference, there is no basis for exchange or discussion among participants that leads to the mutual understanding of something new. [7] Communication ceases to be productive without a context of difference or conflict to initiate change. [8]

It is envisaged that the manner in which dynamic situations can be experienced through the active engagement and manipulation of changing circumstances in the *Conversation Viewer* will assist the diverse consideration and development of mutual agreements. This is where interaction is the product of an individual's capacity to communicate, and develop an understanding of their actions with respect to the thoughts and knowledge of other participants' terms of agreement. Interaction is not considered in a mechanistic sense visualized by the re-positioning of graphical icons that gravitate toward the point of agreement in the *Conversation Viewer's* interface. For that is the resulting material outcome of interaction.

The notion of interaction in the context of this research is centered upon the actions required to reach a mutual goal. This in turn drives the purpose of communicating with different individuals through the *Conversation Viewer*; especially where the development of a conversation is as a result of a comprehensive understanding of a dynamic situation. The significance of interaction is therefore accomplished through the act of doing, which in turn enables an individual to cultivate a shared understanding of the current terms of an agreement.

Ideally, interactive products or services should offer participants, in its system of communication, the freedom to choose how they may express and fulfill their goals rather than being forced to accomplish a task by way of a limited system of interaction. This is where the idea of participating and communicating through a product or service is much greater than its physical manifestation and transcends the materiality of a product. Here the notion of an organized, integrated whole that interconnects people with their environment becomes important. Interaction in this sense is largely concerned with interconnectiveness between all the elements of the design situation. This can be graphic signs and symbols, material objects, activities, services, organizations, environments or systems. What is significant is the active participation of these elements with one another as an organized integrated whole. When all the parts of a design solution are connected, everything is in harmony. This holds significance for the dynamic treatment of a product's content with respect to the form of design outcomes; particularly in the design of products or services like the *Conversation Viewer* that seek to support the changing conditions of dynamic communication systems.

DURATION AND DANCING BEARS: HALBERSTADT'S CAGE, INGE'S BEETHOVEN, ZIMMER'S PIAF AND PITTSINGER'S BIEBER

Chad Eby

This brief paper is a meditation on the technology and cultural resonance of duration-stretched sound.

Still sound is an oxymoron. Sound, as a vibration, is deeply intertwined with time and must move through it to exist at all. People express many of the properties of sound and music in terms of time: time signatures, cycles per second, beats per minute and so on. Unlike the visual component of motion picture film, which can be stilled to extract the atomic image of a frame, or of video, which can be electronically or photographically coaxed into forming a still image, stilling a sound effectively kills it; an oscillator cycling at 0Hz is utterly silent.

However, this dependence on time for existence does not render sound immune to the alteration and manipulation of its silent but necessary partner; instead, the manipulation of sound in time is probably as old as the intentional production of sound itself. Changing tempo for emotional effect was a common strategy in folk music around the world long before being codified in the 'accelerandos' and 'ritardandos' in the scores of European composers of the 18th century. Somewhere in the history in between, the medieval French composer, Pérotin Magister may have been the first documented practitioner of 'slow sound.' In the 12th century, Magister arranged liturgical choral music by extending the syllables of the melodic lines of well-known pieces in time and then inventing new, faster-moving lines as a sonic overlay on top of them.

It was only when technologies eventually emerged not only to describe music through notation, but also to actually record sonic events for later reproduction that a more direct manipulation of sound in time became possible. According to Caleb Kelly, in *Cracked Media: The Sound of Malfunction*, [1] by 1922, French composer Darius Milhaud was experimenting with varying the speed of phonographic turntables; perhaps earning him the title of first 'turntablist.' The comedic effect that could be obtained by speeding up a recorded sample (transforming tenors into sopranos, for instance) originating in public phonographic performances around that time would eventually blossom (or metastasize, depending on your perspective) in 1958 with Ross Bagdasarian's *Alvin and the Chipmunks*, whose accelerated vocals would go on to win five Grammy awards; three of them on the first-ever night of the event. Slowing a recording down, conversely, can evoke feelings of gravitas, sadness or even 'spookiness.' A 2007 study entitled "Does Time Really Slow Down during a Frightening Event?" by David Eagleman and his team, psychologists at Baylor School of Medicine, examined the perception of slow motion often reported in situations of crisis and found that, when sufficiently frightened, peoples' memories get kicked into overdrive, recording minutiae that would otherwise be ignored. This high density of detail in memory, when recalled, is felt as 'duration dilation.' Early ethnomusicologists, armed with decidedly lo-fi recording phonographs, often employed the practice of significantly slowing down playback for the rather practical reason of allowing them to more accurately transcribe and analyze the structure of the music, songs and spoken words they had captured in their ramblings afield. [2]

These intentional and incidental emotional effects produced by altering the playback time of recorded sound samples are due almost exclusively to the unavoidable pitch shifting that co-occurs with changes in the speed of analog playback; since frequency and speed are intimately entangled, increasing the

speed of playback of an audio recording also raises its pitch, while slowing down the playback of a recording lowers the pitch. This relationship is perfectly linear and direct: slowing down the playback to one-half speed results in the pitch of the sound dropping to one-half the original frequency. In September of 1967, American composer Steve Reich fantasized about completely severing this time/frequency relationship, which he elucidated in a conceptual score entitled *Slow Motion Sound*. The score consisted of only one sentence: "Very gradually slow down a recorded piece to many times its original length without changing its pitch or timbre at all." [3] In the late 60s, he considered this score to be strictly a thought experiment, since no readily available technology was capable of such a feat. In fact, the *Phonogène Universël*, a tape machine with a rotating play head developed three years earlier by Pierre Schaeffer in Paris, may have had some success at partially realizing the score, but Reich was apparently unaware of the existence of this exotic European device at the time.

However, even the advent of digital audio recording and playback techniques did not immediately provide the means to realize Reich's score. Basic digital re-sampling of an audio source at a different sampling rate (more or fewer slices per unit of time) does alter the speed of a recording, but also preserves the speed-frequency relationship precisely as analog techniques do. Eventually, in the late twentieth century, new digital manipulation methods finally began uncoupling this previously necessary relationship. With the emergence of phase vocoders and fast Fourier transforms (FFT) came pitch-shifting and pitch-corrected time stretching. Much as digital publishing tools had finally divorced content from presentation, these more sophisticated digital sound analysis and manipulation tools were able to separate frequency from playback speed, allowing sound to finally become 'unstuck in time.'

Four twenty-first century slow sound projects, three of which are digital in nature, and one which is thoroughly analog, may serve as an abbreviated survey of contemporary slow sound projects and provide a means for gathering common threads from recent manifestations.

The analog case is a fresh imagining of John Cage's *Organ2/ASLSP (As Slow as Possible)*. Originally written as a commissioned piano piece in 1985, Cage adapted it for the more continuous-toned organ in 1987. The piece, as the title suggests, is meant to be played "as slow as possible" while still maintaining the proportions of the overall musical structure. The duration record for the work performed by a single human is 14 hours and 56 minutes, achieved when Diane Luchese performed the piece at Towson University in February 2009. The pace of the piece was leisurely enough that she was able to take meals, between the chord changes, while sitting at the organ's keyboard. According to the February 5, 2009 article appearing in *The Towerlight Online* by Carrie Wood ("Fifteen Hours at the Organ"), Luchese also had a mechanism for reserving the nearest ladies' room so it would be available for her use when the score called for a rest.

However, even this feat of endurance pales in comparison to an especially slow version of the work now being performed at the St. Burchardi Church in Halberstadt, Germany. In this incarnation of Cage's piece, human performers are second-string; the notes on the pipe organ being sustained through the needed long durations by the suspension of weighted bags from the keys. The Halberstadt organ is being assembled, pipe-by-pipe, as new voices are required for the piece, but there is no great urgency to the construction. The performance, which began in 2001, is slated to last for over six centuries with notes changing only every few months or years. Crowds gather in the church on note change events, but the organ sounds continuously whether there is an audience or not; the accidental audience of people living nearby the church insisted that the ever-present drone be tamed, so a box of transparent acrylic sheeting was built to enclose the organ and dampen the twenty-four hour sound. Solar panels and a

back-up generator stand by to power the blowers and continue the performance should the electricity ever be interrupted.

This multi-generational sound piece, with the intended duration of 639 years, plays at the extremes of what counts as perceptible time for humans, requiring planning that may exceed seven consecutive lifetimes. However, it does not alter the actual sound *as produced* in time. The sound of the organ itself is like that of any organ and, more importantly, the transitions between notes occur exactly as if the organ was playing a short 'scherzo.' This piece, though very slowed-down indeed, does not directly relate to Reich's 1967 concept. Instead, this staging of Cage seems to point to the notion of duration itself and the kind of organization and optimism and required by humans to contemplate the launching of a project that will not even be half complete within their grandchildren's grandchildren's lifetimes.

The second work is Hans Zimmer's *Inception* soundtrack, specifically the remix (or re-synthesis) of deeply slowed fragments of Edith Piaf's 1960 recording of *Non, je ne regrette rien* (*No, I have no regrets*) used for the signature 'idée fixe' of the film's soundtrack; as well as some clever sound design strategies employing slow sound as markers for transition points.

The relationship between the Piaf song and the *Inception* soundtrack was first demonstrated via a YouTube video uploaded by user camiam321 in July 2010; which by June 2011 had been viewed over 2.5 million times. [4] Other videos soon appeared that also showed graphically how similar the structure of the soundtrack was to a slow version of *je ne regrette*. In addition, slowed down sound cues were used to sonically signal the transition points in the matryoshka-like nesting of the plot's dream levels. Each of which, in the logic of dreams, possesses its own ever-more-tightly coiled time line. Here the slowness is used almost diegetically to express the dilation of time in the upper levels of reality and the techniques employed begin to resemble the ideal decoupling of time and pitch. However, the method Zimmer uses is not so straightforward; and in interviews he hints that the slowness was more a piecemeal reconstruction than a just a slowing down of existing material.

To delve further into the structure of slowed sound, we turn next to the Norwegian Leif Inge's amusingly named *Nine Beet Stretch*. Not unlike the Halberstadt Cage piece, *Nine Beet Stretch* is, first and foremost, a conceptual piece. Inge says he was inspired by Douglas Gordon's *24 Hour Psycho*, [5] in which the Scottish media artist slowed down the infamous Hitchcock film's frame rate until it stretched out to fill a full 24-hour day. While Gordon's work was silent, Inge's most certainly is not.

By slowing down a single recording of a performance of Beethoven's *Ninth Symphony* and stretching it out to more than twenty times its usual performed length without affecting the pitch, Inge reveals a whole universe of microscopic sound and simultaneously makes good on Reich's original idea of slow motion sound. In Inge's piece, tiny sonic events that are quickly overwritten in the mind at normal speed are free now to develop, bloom, spread and skid off in uncertain decay. Close harmonies that create moments of tension in the real time of the original are transformed into long grating passages of dissonance. From my own listening experience, the melody is impossible to follow at this speed, becoming completely unrecognizable – lost both in the microstructure of sound and the failure of my attention; the extreme duration breaking down any notion of 'persistence of hearing.' Even as smaller structures come to the fore, there is an overwhelming sense of blurring, of wobblingly indeterminate beginnings and endings. One of the seeming virtues of *Nine Beet Stretch* is making the familiar strange: critical reception praised Inge for again making it possible to listen to and enjoy a piece that, for many, had become so familiar that it was no longer possible to focus on the sound. [6]

Finally, I would like to consider Pittsinger's glacially paced version of the pop song *U Smile* by Justin Bieber. Slowed down approximately 87.5% (not the widely repeated 800%!) by a piece of clever open-source software written by developer Nasca Octavian Paul and released as *Paul's Extreme Time Stretch*, [7] a software tool that both fulfills and exceeds the slow motion sound criteria and also greatly democratizes the process by putting a very sophisticated fast Fourier transform based stretching tool into a small, free easy-to-use package that requires no hardware more exotic than a standard personal computer to run.

The slow Bieber piece, originally posted by Pittsinger on SoundCloud.com, a 'read-only' sound sharing service, is remarkable mostly for huge number of auditions and comments it received. As many were later happy to demonstrate, virtually any piece of complexly structured audio (such as a carefully produced pop tune) would produce the same species of dreamy, textured soundscapes that *U Smile* did (and, conversely, that speeding up standard time dreamy soundscapes, like the work of Icelandic band Sigur Rós, did not produce Justin Bieber-like results). Perhaps the most significant effect 'Bieber 800' had, beyond giving producer Pittsinger ("Shamantis") a good deal of exposure, is that it started many smart people, including Harold Schellinx at *SoundBlog* [8] and Mark Weidenbaum at *disquiet.org* [9] (both writers to whom this paper owes a great deal) tracking backwards across the historical landscape of slow sound and thinking about the future of audio production.

The story of the twentieth century has largely been one of acceleration. From the physical (the midnight ride of F.W. Marinetti, the Bonneville flats, the four-minute mile, the V2, the Concorde, the Shinkansen and TGV, and even reaching the escape velocity of the earth itself from Baikonur and Cape Canaveral), to the informational (the telephone, satellites, email, and the web): speed was king.

But as we have emerged from the hangover of the millennial party a decade or so later, some of us once again seem to have become profoundly interested in slowness – there are movements in support of slow food, slow cities, slow design and even slow sex.

Perhaps this new-found interest in low velocity is just part of a collective fit of pique because we did not get our flying cars. By which I mean that the beginning of 21st century, so enormously pregnant with visions of the future for so long, has simply turned out to not be how we imagined it. One of our most lauded science fiction writers, William Gibson, has given up setting his stories in the future, because the present is so "science fictional," [10] an extension of his quip, quoted in *The Economist*, December 4, 2003, stated that, "The future is already here – it's just not evenly distributed." Maybe it is the case that we have optimistically leaned into the future for so long, rushing to meet its promise, that we may have run past it without recognizing it. Some of the interest in slowness now seems to be rooted in an interest in pausing and taking stock, to find, deal with and embody all of those futures that have already arrived.

Perhaps some of the interest can be understood in the context of a general breaking away from the formats and structures that have so long dominated recorded music. The temporal limits of 45 RPM, the LP, the cassette and the CD are, along with their attendant marketing and distribution apparatuses, becoming increasingly irrelevant in the time of cheap storage, psychoacoustic compression and high-bandwidth networking. With even a modest portable media player capable of storing days or weeks of music, why not have eight-hour tracks? Furthermore, as storage itself disappears into streaming cloud-based solutions, why have any limits on duration?

In a related thought, I believe the local spike in the interest in slow sound and the DIY movement are related phenomena; the popularity of slow sound may be bound up to a great extent in its astonishing generative capacity. With software like *Paul's Extreme Sound Stretch*, anyone with a computer, a little curatorial skill and the patience for tweaking a few settings can produce their own "ambient epics." [11] With the burgeoning popularity of web sites like instructables.com and thingiverse.com, perhaps the ability to say, "I made this!" will wind up being the majority of the engine behind slow sound.

The idea of the dancing bear, of course, is that everyone is so amazed that the bear dances at all, that there is no discussion of whether the bear dances well; it is enough that the bear dances. The metaphor is an indictment of the triumph of novelty over substance. The ease with which digital tools can now be used to slow down audio, even to absurd lengths, without drastically altering the original pitch is nothing short of amazing – and that it can result in engaging and ethereal textured soundscapes is bound to draw fire from those who produce similar ambient sound work 'the hard way.'

This situation is only a small part of a much larger debate about the ascendancy of the amateur and the celebration of the dilettante, which will without doubt continue long after 'Beiber 800' has faded from all but the search engine's long memories. There is certainly surprise and novelty that something as 'poppy' and heavily produced as *U Smile* could be transformed into something 'transcendent' so easily via even further manipulation. Leif Inge required the talents of a studio of sound specialists and the custom programming of esoteric audio tools (programmers sometimes jokingly claim LISP is an acronym for "Lost in Stupid Parentheses") to pull off his *Nine Beet Stretch*. *Paul's Extreme Sound Stretch*, on the other hand, produces quite good results after less than a minute's download, zero installation and a half dozen mouse clicks. Central to the idea of a dancing bear is not only that the question of the bear's dancing skill does not come up, but also the implicit understanding that the bear could not possibly dance well; we may be amused or surprised, but the bear does not reveal to us anything about dancing.

However, digitally slowed sound may have value beyond its novelty. Certainly, as predicted in many quarters, there has been a deluge of 'Beiber 800' imitators slowing down virtually any imaginable sound who will probably never touch 'slow-downing' software tools after their 15MB of fame. Slow sound, however, whether it be an expression of analog duration as in the 600 year Cage performance, or the visceral experience of using a digital tool like *Paul's Extreme Sound Stretch* to render a familiar melody irrevocably strange, can actually reveal a great deal about listening, memory, sonic emotion and our lived experience of time. If there is a bear dancing here, I would like to imagine him shuffling through a very, very slow but stately waltz.

ART IN PROCESS – CROSS-BORDER AND BEYOND

Elisabeth Eitelberger & Bello Benischauer

This paper talks about the work by Bello Benischauer and Elisabeth M. Eitelberger: ART IN PROCESS (AIP), an Australian/Austrian entity that critically engages with a number of issues/behaviors specific to cross-cultures and consumer culture. We (AIP) develop our projects both independently and in collaboration with other artists at the intersection of installation, video and performance art.

Globalization has opened up enormous possibilities of linkages; it ideally means dissemination, diversity and insight into foreign worlds. However, other than leading to a broad perspective and enthusiasm about the various aspects of this world per se and its cultures, we must admit that – critically observed – globalization very often concludes in generalization and uniformity (shaped and dominated by Western society and lifestyle). It has become the ideal platform for broad mainstream, a playground for unquestioned fast food and monopole society. For artists, in the contemporary context, globalization can lead to the creation of diverse and specific interfaces, establishing new ways of communication and producing (collaborative) work that sets a counterpoint to the various absurd forms of mass consumption.

This paper talks about the work by Bello Benischauer and Elisabeth M. Eitelberger: ART IN PROCESS (AIP), an Australian/Austrian entity that critically engages with a number of issues/behaviours specific to cross-cultures and consumer culture. [1]

We (AIP) develop our projects both independently and in collaboration with other artists at the intersection of installation, video and performance art.

Such hybrid productions, created in-between art genres of experimental dance and theatre, visual arts, music and performance art, are elsewhere referred to and summarized as Contemporary Performance. [2]

In our case, we use new media/technology as a fusing and transmitting element to deliver and increase the transportation of an artistic message to a wider and global audience.

Some of our video/sound installations that have been the result of recent project series (addressing the growing inter-human and artistic communication through interdisciplinarity) are exhibited during ISEA 2011 – *SUEx* (2008), *Intervention* (2009) and *Emotional Seasons* (2010) – and reflect most significantly the general nature of our work from the past decade.

The exhibition and the workshop called *Born to be a Still Life* are accompanied by this theoretical presentation of our artistic practice. [3]

Within our work, we often force an interaction with the public; increasingly through the use of performance art techniques, experimenting with the art functioning outside its traditional spaces. The filmed and photographed documentation of such acts of live performances in public or private space is then used in the further development of artistic projects to finally result in video/sound installations that again can be brought back into the exhibition space (and/or are screened online). Single projects, always consisting of multiple components, are developed over one-year periods.

The recurrent use of language(s) as a strong tool in this work, intends to make people aware of certain issues through sometimes-provocative voice works that lead the audiences out of their comfort zone into a confrontation with their own, mostly unquestioned, behavior patterns. While our work is not didactic it reflects and seizes contemporary issues in our society. In all this work we aim to explore relationships between the human being and its urban/natural environment in various socio-cultural contexts, generally addressing issues related to identity and belonging that arise from globalization and/or cultural structures. Single projects address an elimination of existing distances through borders and barriers between countries, cultures and individual people. We investigate selected spaces of collective and

cultural identities through onsite projects (i.e. through AIRs) and promote art that extends into the social space, believing in the necessity of art that puts use over meaning.

Bello Benischauer, after working as an artist for more than twenty years, went global with his projects on a regular basis since his formation of AIP with partner Elisabeth M. Eitelberger, who is artistically involved and accompanies Bello on a theoretical basis. Since the age of eighteen, Bello has become increasingly interested in a combined use of diverse artistic techniques and finally set a special focus on new media – particularly video/sound installations – connecting visual images, spoken word and sound. Bello spent ten years in South and Central America, Pakistan, Iran, Nepal, South and East Africa, Indonesia, New Zealand, India and many other places in Australia and Europe, which results today in a deep connection to world-cultures and led to a special interest in the world's varied socio-cultural milieus.

Traveling and the constant aim to connect to different cultures through its people, lead to the manifestation of Bello's ideas, realized within our projects. These ideas do not refer to particular theories but are influenced by our immediate surroundings, by the media, by education; and depending on and shaped by our own individual cultural heritage/history and its multifarious, social layers. In becoming an extremely globalized world, not only the Western image of art has changed but also the exhibition space as we know it has died. Art lives now in cyberspace, it happens within the social space; it spreads out into our daily surroundings and many artistic ventures are sidetracked by less sophisticated projects, among others influenced and a result of cyber culture and social media. The French writer and theorist Nicolas Bourriaud addresses the shifting of the worldview according to developments within the arts. He describes how use over meaning in art has developed in recent years and how the Internet leads into a new direction of artistic expression. Under the term of Altermodernism (following Postmodernism) he addresses the global movement of engaging with the Internet as the main tool of expression, expanding the artist's possibilities to interact with the world instead of reflecting only on their own cultural heritage. Bourriaud refers to this global culture as the "playing field" for artists to experiment and to start building new forms of expression – influenced by and associated with the World Wide Web. He sees the human frame of mind today characterized by a global culture, dominated by exchange. In his opinion, Altermodern intends to define the actual modernity according to the specific context we live in: globalization, and its economic, political and cultural conditions. In an interview he states: "The core of this new modernity is, according to me, the experience of wandering – in time, space and mediums." [4]

Speaking about our own work, it also grows out of a reaction to the present. It translates our individual perceptions into works of art; it transmits our thoughts and feelings/emotions into an interpretive and aesthetic object (a wall-object, a video/sound installation, a social sculpture, a performance act) that becomes an artistic statement. It engages with people through the work process and the process itself becomes the main artistic outcome.

Questions like:

- a) Why has it been crucial for us to start forming international collaborations with others and to work in an interdisciplinary fashion across media?
- b) How does our work, based on surveying cultural likeness and differences in terms of identity and belonging, respond to modalities of globalization, growing urbanity and multiculturalism?
- c) How did socio-cultural issues become the main theme of interest?

... are currently under review for an artistic monograph called *Cross-border and Beyond – ART IN PROCESS until 2011*. This monograph will document the work by Bello Benischauer and AIP chronologically, complemented by philosophical reflections on single works.

In recent years, we have intensified our work methods concerning the use of languages and the collaborative aspect of inviting other artists into the process of our projects. Four of these resulting video and sound installations are shown in an exhibition during ISEA 2011.

SUEX (Sustainability and Extinction, 2007–2008), a four-wall video and sound installation, is designed to confront the audience with different voices (and languages) and asks to overcome the need to communicate exclusively through language, as well as highlighting how easily we tend to ignore what we do not know, or rather what we do not want to know. The basis for this work was an aphorism in sixteen sequences by the artist that was translated into Hebrew, Japanese and Noongar (language of Indigenous Australians, southwest corner of Western Australia) by collaborating artists. However, *SUEX* really looks for a communication beyond language (barriers) and explores instead, how individual languages can be used experimentally – just as a tune, a sound component. The four videos play simultaneously, 'speak' to the viewer and try to get his attention by building a conversational atmosphere in confrontation to the viewer. Other projects made before *SUEX* also questioned the social impact of human beings on nature through mass consumption and globally increasing population. [5]

Throughout the last century, many artists started to incorporate the use of language in their work, implementing certain/different meanings, effects and uses of language. In our case, we use language as a tool to question: Do we need to understand the words? Is there an understanding beyond our languages? In how far can we expect others to accommodate to 'our' lifestyle/cultural peculiarities and are we willing to accommodate/adjust to theirs?

In 2009, we developed an international project series called *INTERVENTION* that explored certain places and their cultural meaning through simple live performances in public. The project series was meant to explore the term of 'intervention' in its artistic meaning and beyond in different cultural environments. The places of this investigation arose as a result of other AIP activities at that time – in Austria, Portugal and Ghana. *INTERVENTION* has resulted in a book of photographs, text and a Blu-Ray Disc with video and sound installations. [6] The original English text and its translated versions in Portuguese and Fante served as a fundamental part of the sound composition. Part 1 – Salzburg/Austria questioned: How do we fit – as an individual – into a space? We investigated how reactions from the general public influenced the intervention itself. Part 2 – Évora/Portugal looked further, examining interventions that happen between people/bodies; how we interact, intervene, interfere and how we individually grow into what we finally are: individual beings, formed by culture, society and language. Explorations in the use of movement, dance and rhythm: dancers created situations together in a public space and in private – building communication through movement; addressing barriers, anxiety and cultural misunderstanding. Part 3 – Kumasi/Ghana explored human beings and their immediate surroundings to discover what actions can destroy others, or interfere with their environment. This part evolved from the discussion about creating appropriate environments for people – both in general and in particular places. It investigated how local resources could be engaged most efficiently, how art might act as a communicator to initiate real action within the social space and to overcome cultural differences. The work created in this particular context turned the word 'intervention' into a poetic experience and took the notion from a place of fear and resistance to one where it was able to evoke a sense of enrichment, enhancement and belonging.

The *EMOTIONAL SEASONS* (2010) project series was again produced in collaboration with other artists and resulted in various parts: *Christmas*, *The Cloned City*, *Not quite Kosher*, *Fool's Gold*, *Off Season* and *Internal Room*. Collaborating performances have taken place in Australia, Austria, Dubai, Ghana, India, South Korea and the United States. The series of works investigated aspects of the core theme of AIP works: how integration or exclusion is felt around particular cities and urban places. This project series generally addressed individual issues observed and experienced by the single artists about identity and belonging concerning aspects of globalization, while living in culturally diverse societies and by focusing on how they would explore/experience their immediate environment themselves in a certain, sometimes contrived situation. Questions that helped to shape the process included: How strongly are we influenced by the materialistic world we live in? How does it feel to live in a foreign (cultural) living environment and how does this affect us personally? Which layers of reality do we create and inhabit? Two of the works exhibited during ISEA 2011, *Not quite Kosher* (developed in Vienna) and *Fool's Gold* (developed in Sydney), are both based on two individual, abstract plays, we wrote for the process. The fragmented text of both plays has been used to develop performance parts in public and private environments that were filmed and further developed into the resulting video and sound installations. [7] The human body (in white clothes in *Not quite Kosher* and nude in *Fool's Gold*) was employed as the main tool to express a full range of emotions and feelings to which the viewer can relate, regardless of background, sex, education, culture, or ethnic identity.

Many aspects of media art and its ephemeral character, process orientation and its temporality have influenced our work methods throughout the years. Cyberculture and new technology increased the interest in an interdisciplinary and – within the arts – the hybrid process of crossing media once again. This is nothing new, it just appears as a new form of an old system; praising plurality over singularity. Contemporary art's perception has reached a different level. A shifting takes place: the process itself has become the object of contemplation. The artist traveler (in real and in cyberspace) explores global culture(s). Today we look beyond our daily environment. Other surroundings can extend our worldview, influence us and become an integral part within our own developing work/life. In our artistic projects we ask questions about the connection points between real- and cyberspace, asking how people's perception, how global culture – in general and specifically – influences our way of thinking and how this can be translated into works of art.

Globalization and new technologies, the Internet in particular, lead to an expansion of our worldview. Extensive developments on various levels urge us to reorganize, reshape and rename certain aspects of human existence. A constant questioning of our immediate surroundings can help us to build new solid structures and may enable us to find a new orientation within this explosively growing world, in which we have to redefine our understanding of identity and belonging.

NEXTENSION: THE ADVENT OF THE NETWORK-SCREEN

HERLANDER ELIAS

The expansion of the current media-environment due to user-generated content, portable media and social networks has changed the very notion of citizenship. We live in a post-Web world and the network-screens are extensions, they perform as portals to digital space. This is the Next Tension.

1. MEDIACENE

There was a time when there was no media-environment. As technology became part of our culture so did media. One medium after another we have woven an entire environment out of media. It began with print and it did not end on the iPhone.

The society of our time worships contents according to their activities and hobbies. Today there is no fence separating users from programmers, culture men from technology women. Indeed there aren't borders between technology media, structures, patterns and contents anymore. Perhaps we could call it the Mediacene, the moment in history in which Man changes his environment, based on media.

This is the thing: The corporation world of the 80s and the wired world of the 90s have merged into one entity alone: a user-driven techno-cultural economy. Such new media-environment is what we may call now the "post-Web" world. Yes, the World Wide Web, the Grid, cyberspace, the Internet, provided ways of functioning and entertaining we cannot disregard. Thirty years ago everybody thought we would get inside the computer world. Twenty years ago we were supposed to interact with media by means of helmets and datagloves. Ten years ago computers were supposed to run vehicles. Today we use touch-screen media, we drive GPS-guided automobiles and we have declared war on depth with 3-D cinema. If there was a border between images and reality now it is gone for good. Augmented Reality is an example of this.

We carry several portable media with ourselves and computers update themselves on their own. We speak to our GPS interfaced cars and rely on Google Maps. This not anymore the planet inhabited by Man in the once Anthropocene age. It is simply the Earth from Google Earth, a media-feature used by Men in the Mediacene age.

Lev Manovich said once that "for the first time, space becomes a media type". Such statement is so much daring and true. Since cyberspace appeared on early videogames that virtual worlds, digital cartography and electronic mapping became a fact. Behind most of our media-environment's innovations over the last decade there is map technique. Now high-resolution maps take place because of the Web's appearance. As I have said previously, this is a post-Web world. And in this moment of history, each second counts and the clock is still ticking. Should we examine better these change we should mention the advent of the "network-screen," something only possible due to the awareness of our living in a "civilization of the screen." [1] Put another way, we may understand the whole media-environment thesis by comprehending first how instead of a screen we had a network-screen. Rather than being just a computer-portal to the Web world, screens and networks got married in the 00s following a similar trend as in the 80s computers were attached to telephones.

Wherever we are standing, the network-screen grants access to data, helps us finding things and eventually reminds us of things we once were looking for.

At the same time, the Mediocene establishes that media are futuristic, as if the imagined tomorrow is today's idea. In fact, most by-products of our time are simultaneously futuristic and rely on ergonomical designs. They're a sort of prospective concepts.

Of course it is not much to highlight that in the Anthropocene, Man is believed to have changed the landscape for good. Once we understand what is at stake in the media-environment we notice that most of things surrounding us, consumer products and images, resemble "post-relief" artifacts. After three decades of hard digitizing and databases' enlargement the desktop computer became a tiny netbook, mobile phone, a smart appliance useful for using everywhere, any time. It is getting harder to distinguish as times goes by what exactly belongs on the other side of the screen and what does not. So far maybe unfortunately we are creatures of screens. Computer after computer we have built a Matrix, a real one, a high-end computation network, a media reservoir for hybrid images, the very foundation of the computer as a "metamedium." [2] After this development a computer is not seen as a household appliance, office hardware or geek gadgetry. From this moment a computer is an open portal to a network, a vast world of data. So one should not think of Gibson's characters in *Zero History* novel as being awkward whenever they're "Decked." [3] Everyone is "decked" these days.

2. APPLIED SPACE

Our next range of possibilities in working performance and entertainment features fits in the new media-environment. Computers, networks and communication sciences become one universal recognizable entity, something every person notices on media screens, in the media space, which is an "applied space". Once a person uses software and triggers information commands, a new bridge is set between the screen-world and real-world. The space where we step in and out is an applied space, and interaction happens across media-screens, henceforth becoming limit-surfaces. As users make these media their world-center all options are set on them, every track record, each choice, all things to share and recollect. On the other hand we are witnessing a transition from a pre-digital world to a fully-digitized world. What else is left to scan and digitize? What else? Right now we are for sure living in a cyborg place, since we still know we are mostly human, modern progress believers. Yet, living in pre-cyborg places was a very different experience. You really had to be there. People connected online across the Web in their limit-surfaces try to search and be found, to collect information and to belong to a larger collective. It looks like we too have a match between the collective and the network. Yes, we have. It's called "social networks", a new 21st century phenomenon.

Our time is positioning us in a new condition, for we feel like we are hostages in a liquid present. An ever-expanding media-environment digests, changes, reconfigures any element that comes across its ventures. Multiplicity became a rule of the data world. We have to understand that in this media age reality becomes multiple. It is imperative this "multiplicity", it corresponds the endless range of options that Chris Anderson mentions in the *Long Tail* book (2007). Multiplication is also a characteristic of the media-screens, video-windows, multitasking, chat dialog boxes, and so on.

A new context is available and it forces us not to choose resignation. Choose options. Create options. Citizens are now equal to consumers, and they have to be global consumers and global citizens if they do not want to face oblivion and time standing still. Thus, we are left with two new elements: cities

have to be full of new citizens, and cities have to be global. From people's point of view a new character emerges: a citizen of the world. Greek-Hellenic culture had a term for this: *philoxenia* (love thy self, the other, and long live the art of travelling). Our sole condition is to embrace the eternal adventure, the trip into an environment where we stay in touch to our network of friends on a global level. Media change the city and society. Suddenly the urban world and the media world seem to be the same world, a "big neon city", in the gibsonian sense. After all, it is true that "cyberspace" resembles a city, and we cannot stop noticing that metropolises and sprawls look like the cyber world of rendered icons of data flowing in every direction. Digital Las Vegas, perhaps.

Evolving digital space has made many things possible, mostly customization. Users, players, workers, programmers, artists, designers and technicians opt each one for their favorite elements. Our digital world is the applied space, where applications follow user's expectations and motivations, skills and preferences. A bridge could be linking both the excess by-product of supermodernity and the customizable media-environment surrounding us.

A massive array of new brands (Google, Amazon, Facebook, Apple, Twitter, Netflix, etc) makes us more and more dependent on this applied space. Our eyes are glued to media-screens everywhere we go. Once Manovich defended that "We still have not left the era of the screen" [4] and so far it is still true. We haven't left the screen. In fact it is going that way. Some things only exist inside the screen, as a world of applications available and data do. In order to understand this applied space, one has to recall that cyberspace in the last century visionaries' jargon meant "control". Remote control. The power of the world in the palm of our hands. Working on different programs at the same time. Standing or walking on different worlds at the same time (GPS, videogames, Second Life, real world) is also a multitasking phenomenon. All this multiplicity and overlaid grid of available things to do by the new urban global IT citizen is about cyberspace.

At first, the applied space of today's iPad and smartphones is cyberspace. That is correct. Though we have to accept either that cyberspace is "whatever you view on your computer screen, the electronic geography you traverse when you are on the Web." [5] So ultimately, this is all about geography. What technology allowed us to do since 1994, on a mainstream level, is to traverse, avoid, overtake, transnational borders. Fences are rendered meaningless ever since the Web came up. Which type of space is this? Gibson himself in the text *Chaos & Cyberculture* (1994), in the interview conducted by Timothy Leary, tells us it [cyberspace] is "notional space." [6] So here we have the ground set up for the advent of the "network-screen." If there was a time in which each geography had its own screen codes, that time is long gone. "Notional space" has provided us with the tools to use the applied space of the digital age: "geographics". From Google Earth, GPS, Geocache communities, the applied space of control became "the grid", the ground upon which everything has been established upon. A major contribution about this issue is provided by Higgins, as she says that "the persistence of grids demonstrates that once a grid is invented, it never disappears." [7] Cyberspace is that grid, the Web is that grid. Something we can never uninvent. It's not technology we are discussing here. It is culture, a mankind landmark, an American product to civilization. Though one thing is still working on one hundred percent, the fact of each new media image being something where the user actively goes into. Why it happens is answered by Svetlana Boym, who believes that "the computer medium is largely tactile", not merely visual." [8] The computer tablet revolution, with their promising applications, proves to be a good applied space, and it shows how Boym is quite right about it.

3. NETWORK-SCREEN

All we know is that in 1994 the cyberpunk visions of the “datascape” became true by the hands of Timothy John Berners Lee and Robert Caillau whom have tested the HTTP communication design between servers online since 1989. Yet cyberpunk authors did amazing discoveries, they imagined how audiovisually and interactively things would be like. William Gibson admits such logic by assuming that “Well, if there’s space behind the screen, and everybody’s got these things at some level, maybe only metaphorically, those spaces are all the same 'space'.” [9] Despite the “newness” of his words, the point is that what today we take for certain this post-Web world and how we interact with the network-screen, yet it began in the 80s.

Media-environment users actually belong to this new sphere, the realm of control, they have grown or matured within a "post-Web," "post-cyberspace" world. Beyond this a new characteristic is implied in space-consumption, since space became translated to images (First Person Shooter videogames, Google Maps, Terragen software for virtual landscapes), or at least computer-generated, and that is how we became “user-players”. At the same time we play and use, we travel, work and entertain ourselves.

By staying connected to this universe all interaction depends on the user's position and his tactile skills, like typing, rotating, pinching, pressing and moving icons around. So, if it’s a question of space, digital one, and if people must be users, the network-screen is the hardware-software combination which establishes best the new interaction mode with the digital world, the media-environment.

For the very first time a culture appears, being produced by “everybody”, rather than by an intellectual and social elite, regardless of national borders or social class. Now, the network-screen provides worldwide access to a screen across networks, and that is the screen of new Web 2.0 and upcoming 3.0 brands.

People feel driven to the Web world. All there is one finds it on the Web. If one does not find it that is because it is likely inexistent. More and more students upload their CVs and portfolios online. Pictures are being uploaded to Flickr, videos to YouTube, short global messages composed on Twitter accounts. For professional reasons they are connected to LinkedIn and whenever they can they chat in Facebook, Orkut, Baboo, Bebo, Digg or Hulu social networks. All the people online together outperform small cities in terms of communication flows. Some countries are smaller than the amount of online users in some social networks. The advent of the network-screen is marked by another event, the fact of circa eighty percent of users being mobile nowadays, updating anywhere, anytime.

Cory Doctorow says that "the networks that emerge are owned by everyone and no one." [10] Digital world democratizes and then is turned into a corporate cluster. This too happens. It is a second nature what we’re discussing here, and right now it is huge. Today we need a “postmedia literacy.” Media started in the mud brick of Mesopotamia all the way to modern wax disc or contemporary PlayStation and iPads. And it does not end here. As the media-environment keeps growing, a “contiguous record”, a "continuous-memory" of the digital realm, improves our information and access to it. Network-screens are so global and relatively cheap these days that sometime we forgot a major part of Earth’s population has no access to cyberspace. Regarding the true substance of cyberspace, Boym highlights it is basically “datacentric.” [11] Judging by the amount of search engines and new Web sites, ebooks now available and so on, one may think a new type of person is needed in this data world. New media has new performances. Therefore, it changes the user and the player into a sort of “data-pilot”. The wider "networking" and "data collecting" event turns people into data-pilots. Due to this, one could invoke as well the concept of transmedia event. Is it possible to describe what exactly is going on? Yes, it’s a phenomenon of “global palimpsest”. It works as an ever-increasing space of posts, blogs and news from everybody to

everybody. Like a self-growing empire of records, in the Wiki age, and some narratives move from one medium to another. Consumers keep following them.

Today 36% of Amazon books sold are digital releases for the Kindle system. We no longer search for the news, the news finds us... Networks of news are established, people gather around contents. Communities grow upon content interest, depending on which records are published, available on the network-screens.

Our media-environment keeps increasing and turns other relatively new things into obsolete items. Online is no longer a state of digital citizens, it's a law. Nobody separates computers from networks. The digital is obviously the network. It hardly seems unlikely how for some time both things, computer and the Web, were separated. "Cloud computing" establishes this at its best.

People are looking for collective waypoints. GPS and GeoCache community and the social networks are symptomatic of this substantial problem. People gather, link, unite and move towards common waypoints. Cyberspace still is the perfect spot for sharing those waypoints. It can work out fine for sharing GPS coordinates as well as ideas, texts, pictures, designs or mathematical concepts.

Our network-screen world, our attachment to the mobile media-screens is a new thing. But what leads us into it is quite old. We need the past memories and the tribes. A man without culture is an empty vessel. Yes, we live in a screen culture, and now all screens are linked together, they are so flat that images seem to acquire more depth than their media.

It is a question of performative subjectivity too. People, subjects, perform, they share, work and function based on their convictions. It is not an objective data-based world, it's a subjective-relying network. This is our time's identity card. No one can predict anything anymore, if all that happens is recorded on the Web. As soon as the network-screen has it all, everybody around the world knowing something could trigger unforeseen consequences. The more people know something the likely change is taking place. Things become impossible to anticipate. Soon there will be not much differences except those of performativity. Performance will determine how things unfold. Based on performance one will be capable of predicting the future. This transition is better explained by Gibson, who says "We're all doing VR, everytime we look at a screen. We have been for decades now. We just do it. We didn't need the goggles, the gloves. It just happened. VR was an even more specific way we had of telling us where we were going." [12] In the aftermath of this thinking, the point is that now each network-screen is a portal, a door to the media-environment, we are before the NEXTension.

SONIFICATION OF EMERGENT URBAN EVENTS WITH GRANULAR SYNTHESIS AS AN URBAN DESIGN TOOL

EMRE ERKAL

As the contemporary city emerges as a dynamic field, new temporal dimensions with inter-scale relationships have to be included in urban analysis and design, such as urban mobility. The auditory sense equipped with ecological psychological principles is fit for the task of tracking emergent events. An urban design tool is proposed and partially implemented in the form of a sonification environment with operative principles of granular synthesis.

Crisis in Contemporary Urbanism

Parallel to the increase in problems due to contemporary urbanization, it is not possible to state that today's cities are better analyzed, designed or known, all yielding to a current crisis of comprehensibility. One set of reasons has to do with the qualitative change in the urban realm, while another set of reasons arise out of the tools we try to understand our cities with.

Urbanization in many parts of the world yield to an increase in size, density and depth of cities. If megacities constitute one facet of the phenomenon, shrinking cities constitute another. In addition to this complexity, we are facing the impact of information and communication technologies (ICT's) in the urban realm. [1] For several years, it has been well-researched and understood that the relationship is more complex and ICT's and the large metropolis effect each other and therefore a more intertwined and hybrid view of space has come up. Recognition of double sided effects bring opportunities as well: these technologies might be utilized for the design of contemporary urban areas, in the form of new urban design tools.

Urban Design in Today's World: The Need for Design with New Concepts

The paradigm for Urban Design originated in 1950's architecture culture, when the capacity of public spaces in cosmopolitan city centers were questioned to be the vessels for the public sphere. Initial conceptions had more to do with devising an architectural vocabulary for symbolic identification of public space with the public sphere. However with the Team X group, urban designers concentrated on the manifest forces of publicness across a variety of urban spaces, not necessarily on 'publicly owned spaces' to begin with. Similar ideas were circulating in the zeitgeist of the post-war western circles of architecture and urbanism. Jane Jacobs analyzed the condemned urban centers in the US, and documented lively mechanisms of self-regeneration in these neglected neighborhoods. Jacobs was the first to utilize mathematical concepts of self-emergence over social networks, in fieldwork.

Since then, Castells' notion of "space of flows" and the "network society" have come to dominate urban thinking, in response to developments that can not be explained with classical notions regarding how cities work. [2] As contemporary urban design theory utilizes the concept of space of flows as the new logic of urbanism, dynamical concepts that take into analysis the flows and mobilities of people, goods, energy, money and information over what is deemed to be infrastructure become instrumental. These views take modern urbanism as complex processes playing out on complex fields over time. Relationships and links occur across many scales and vast distances.

We choose to concentrate on one such dimension: urban mobility. Barley recounts "choreographies of travel" in London, where definitions of center and edge are constantly re-emerging. [3] The physical aspects of mobility could be the indicators of forces and relationships in the social realm. Movements of crowds in urban spaces yield to the view that cities today need to be understood in terms of ever-changing possibilities. Koolhaas' work on the city of Lagos showed that the city has massive flows of people and goods in uncategorized and unregulated ways. Koolhaas' documentation of mechanisms of self-regulation and emergence begin to propose Lagos as a model for the future of urbanism in the industrialized world. [4]

As an example, seemingly unused interstitial spaces in between highway bridges act as arenas for organizing junk for re-use. Collection and dispersal rhythms of metal or tires could turn any seemingly irrelevant space into a temporary logistics center. Emerging megacities, such as Lagos or Istanbul might be illustrative of the dynamical forces of mobility, with infrastructure in formation [Fig. 1].

Tools for Monitoring Urban Change

CONTINUUM BETWEEN MICRO AND MACRO PROCESSES

If this is the future for the cities, what could be the parameters for studying and comprehending these forces of mobility? Therefore, analysis and intervention could begin with the notion of the event. Events in modern architecture theory have come to signify well-defined observable sequences in spatial configurations, yet events in contemporary urbanism are emergent singularities where novelty comes not only with re-occurrence but also with undefined categories. In other words, an event could emerge in an uncategorized way. Thus, as an event arises out of a recognition, it is a phenomenon of perception.

Mobility at larger scales signify a swarming of the individual movements and linkages; and the type of knowledge one aims to arrive at is about the large scale implications. When faced with micro-level changes in patterns of movement of people, the moment of recognition that a novel event has occurred becomes critical. Deleuze reads Leibnitz's work as he defines the passage from micro-perceptions to macro-perceptions: for him the role of perception is about the "granulation of the world and spiritualization of the world's dust." [5]

EVENTS IN ECOLOGICAL PERCEPTION

For discussing the problem of comprehension of urban intensities, a distinction could be made between model-based and event-based approaches to cities. As inheritors of classical urban planning tools, model-based approaches develop a map, an enhanced representation of the city based on pre-determined categories of inhabitation, use, linkages and event types. They are inherently ontological: the approximation of the representation is crucial to the information that can be extracted from the model/map, regarding the large scale undergoings in the actual city. Model-based approaches show a great variety: ranging from absolutist intelligent maps to computer simulations that are constructed from the vantage point of a single generic observer. However, as this observer is generic as well as the city, the model keeps it distance from the actual city.

Event-based approaches could be defined by taking the actual city and the actual observer as the departure point. As an observer in the city is part of the physical environment and the information he/she receives could be understood in terms of embodied cognition. Embodied cognition implies that information – and thus knowledge – of the actual world has to be communicated to the individual through sensory and perceptual channels that are physically coupled with the real world, as opposed to the view that observers are static receivers of sensory data. The work of J. J. Gibson in ecological perception has been fundamental for the development of this line of understanding. For Gibson, the information for perceiving events are a result of the individual's being in the environment he/she perceives. [6]

However, for developing an urban design tool, comprehension of large scale events are crucial. As an observer is limited with his/her physical existence, the problem of the comprehension of large scale

workings has to be developed with the principles of embodied cognition. Embodied cognition implies that information – and thus knowledge – of the actual world has to be communicated to the individual through sensory and perceptual channels that are physically coupled with the real world. For tackling problems of detection of events in ever-changing flows, pertinent sensory channels must be selected for conveying information. Processes of hearing has been shown to deal with temporally varying intensities better than vision.

Sonification with Granular Synthesis

ABILITIES OF HEARING IN THE EXTRACTION OF TEMPORAL INFORMATION

Sonification is a set of techniques where information is transferred with sonic elements, other than speech. Temporal nature of sound and hearing allow real-time information to be monitored constantly. The most widely known early application of sonification is the Geiger counter, a device which instantly tells the amount of radiation its sensor counts with a series of clicks: density and intensity of sound elements convey information about a landscape of ever-changing real-time data. Studies show that auditory monitoring of emerging events allows faster detection, compared to just visual monitoring or visual and auditory modalities combined. Hearing is simply more equipped for the detection of real-time change. [7]

Early sonification applications utilize musical qualities such as pitch variation in order to indicate the magnitude of change in the observed parameter. However, more recent applications try to utilize human auditory capabilities for information extraction about physical magnitudes within the physical world. Human hearing can extract information regarding the physical events that occur among physical objects in its surroundings: density, malleability and weight of objects are easily reported.

The data that needs to be sonified has to be mapped onto auditory parameters according to its dimensions. For monitoring parameters regarding change in the urban realm, issues of scale is critical. Furthermore a gradual change in parameters such as densities over a region has to be mapped gradually. In the literature there are sonification examples for geographical information which are direct translations from visualization. Zhao et al propose a four-part system: overview, navigation (zooming), filtering and details-on-demand. Performance is difficult to document, and yet the results are in accordance with other basic research that theoretically disparate dimensions such as timbre and amplitude are not totally independent. [8]

These studies show that the design of sonification becomes crucial for its effectiveness. In order for the hearing observer to make sense of the sonic input, the design of the system has to begin with auditory capacities that are to be tapped into, rather than imposed classical music theoretical categories. Trevor Wishart puts forth listening in the frequency domain, and discusses the potential in much neglected noise spectrum. Wishart is interested in the listening of a dangling telephone wire in the wind, where the sonic output is connected with the physical properties of the wire itself: its mass, cross section etc. [9] These physical parameters are directly embodied in the sound generated, and furthermore the human ear is capable of extracting information regarding these. Therefore, a natural morphology of sounds could include: crack, turbulence, wave-break, bubbles and similar physical processes.

Physiological research into auditory scene analysis, backs these holistic views. Bregman provides a framework for understanding hearing in an ecological point of view. [10] In Gibsonian psychology, event replaces sound-object as the unit of analysis. Bregman takes it further and proposes that flow is pertinent: a series of footsteps tells us about haste or laziness whereas a single footstep sound is irrelevant. Following this logic, it is plausible to propose the address the kind of hearing of layered events in sound streams, that extend across micro and macro scales. What is critical for urban fields is the capturing of dynamic morphing qualities in the continuum regarding the movement of individuals amassed. Wishart extends the analysis into group phenomena proposes streams of micro-events producing a sound landscape that is continuous across scales.

PRODUCTION OF MICRO-SOUND FOR TEXTURAL DEPICTION

One particular technique that could be instrumental in the implementation of these principles is the technique of granular synthesis. Granular synthesis is a synthesis technique devised with slightly changing micro scale sound packets produced in unison. As masses of 1 to 100 millisecond long sound quanta come together in clouds, their variations produce macroforms. Simple changes in simple parameters like the duration or the density of the granules yields drastic transitions. The potential of granular synthesis for the monitoring of the full variation in the spectrum is illustrated in the Keller and Truax study. In this study the sonic material of water drops were used as granules, and masses of these sounds were then varied in density and flow speed to fully invoke sensations along a continuous spectrum ranging from sequential water droppings to the flooding of a river. [11]

In terms of sonification, granular synthesis techniques provide an invaluable set of bricks in portraying varying textural data, such as urban fields. For implementing a sonification environment for real-time change, an observer is crucial, so that real-time intervention becomes meaningful. The more textural the granules, the more embodied will be the sensory integration for the observer.

Design Tool Implementation

THE GENERALIZED CASE

An urban design tool is proposed to track emergent events within mobility patterns happening over time. Real-time change is dynamic, yet classical planning and design tools are incapable of capturing. This proposal rests on the assertion that an operator is crucial to assess the emergence within the flows. A disembodied computer model will only be able to detect occurrences of pre-determined classes of events. For the detection of novelty, a mechanism tapping ecological perception can to be utilized.

Sonification with granular synthesis has two advantages for the task: utilization of the auditory modality for fast detection of temporal change, and micro-level granular change allowing for textural depiction of a phenomenon played out on a spatial layout. Mapping is straightforward: persons could be seen as singular moving particles, and each person's movement can be sonified in its own terms. This movement will occur in a given urban spatial configuration. With interactive parts within this configuration, an operator could make decisions and change the parameters of these moveable parts according to the emergent events she recognizes. This constitutes a feedback loop where the operator becomes enmeshed within the system she observes: in real cities these moveable parts in urban spaces do exist, however they are in the hands of security experts, not designers.

Therefore, the overall tool is conceived of in several parts: sonification of moving agents, the feedback design loop and the piping of real-time mobility data from real-time cities to provide for the agents. As the total project is an ongoing venture, the purpose of this essay concludes with the discussion of the sonification and feedback parts.

INITIAL IMPLEMENTATION: PROOF OF CONCEPT

A Max/MSP/Jitter implementation of the analysis counterpart is based on a modified version of the original Boids algorithm by Reynolds. The urban field is represented as a two-dimensional surface on which agents are set in constant motion. In the original Boids algorithm, each agent moves according to simple rules: avoiding collisions with neighbors, trying to align its speed with the speed of the group and aiming for the instantaneous group center. As all agents are on the move, the center and the collective speed is constantly changing; an ever-changing swarm of agents are simulated [Fig. 2].

In order to complete the feedback loop, a few objects are placed in the field. The operator can change the orientation of the objects. These changes bring forth more dimensions to the complexity of the system. A real-time coupling of the operator's sensorium with the chaotic system forms an embodied coupled channel, working its way through the auditory system. The emphasis should be placed on processes of hearing with granular synthesis, rather than the closure of the feedback loop. With textural depiction, changes across many scales – ranging from the micro to the macro – will be audible, and yet responsive to miniscule changes in the operator's actions with objects.

Conclusion

For the first portion of the urban design tool, an embodied feedback loop is established between a dynamical phenomenon and an operator/observer through sonification. Granular synthesis allows a textural depiction of the event landscape, the resulting sound-field is capable of portraying miniscule changes in parameters for the acute ear. There are numerous granular synthesis techniques that need to be tried out to develop an understanding of the kinds of emergence each technique is sensitive to. For example with the implemented 'pulse trains', tight convergence and staggered cross-passage phenomena were strikingly recognizable.

BRANCHED SURFACES AND COLORED PATTERNS

JUAN ESCUDERO

A cell complex is defined in the analysis of the topological invariants of tiling spaces. In some cases the complex contains collared tiles. The representation of the corresponding branched surface can be done by assigning colors to the collared tiles. This allows to distinguish tiles with the same shape but different edge identifications.

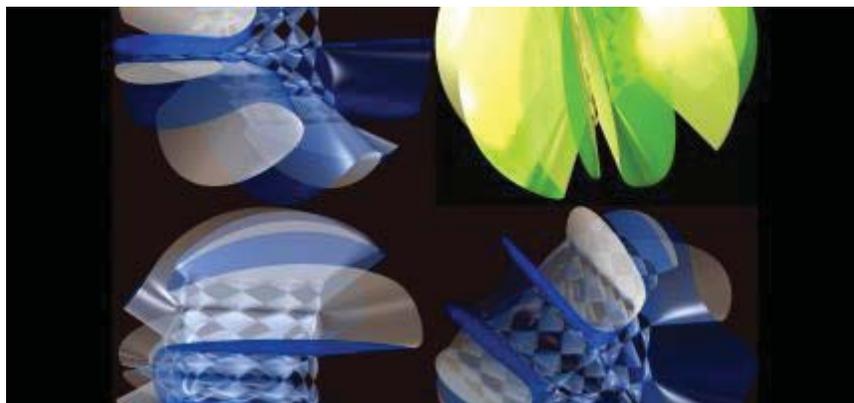

Fig 3. “Nueve y 220-A” is based on a nodal surface with degree nine and cyclic symmetry.

1.-Introduction

Artists, scientists and mathematicians share instinctive feelings about order and disorder. One of the fields where this is apparent is the mathematical theory of long range aperiodic order, because of its implications in the arts.

Aperiodic tilings are geometric objects lying somewhere between periodicity and randomness. In the 1960's Wang and Berger introduced aperiodic sets of tiles in the treatment of certain problems in logic. The question was whether or not it is possible to determine algorithmically if given a set of tiles they tile the plane. The cardinal of the tile sets was very high and examples with few prototiles were constructed later by Robinson, Penrose, Ammann, and others. Since the discovery of quasicrystals in the 1980's, the generation of ideal quasiperiodic structures has been a problem studied mainly by mathematicians and physicists.

Recently it has been suggested that aperiodic order already was present in the medieval islamic architecture. [8] Periodic and non-periodic girih (geometric star-and-polygon, or strapwork) patterns were on the basis of the designs. In particular by using certain substitutions in five girih tiles, a pattern on the Darb-i Imam shrine (Isfahan, Iran, 1453 C.E.) can be mapped into a decagonal quasicrystalline Penrose pattern with few defects. The girih tiles have the shape of the decagon, pentagon, hexagon, bowtie and rhombus. They can be seen in one of the panels of the Topkapi scroll (Topkapi Palace Museum in Istanbul), drafted by Islamic designers to transmit architectural procedures. The authors in [8] also claim that a selfsimilarity transformation, or subdivision of large girih tiles into smaller ones, was known by islamic architects.

In the 20th century, there are also many examples of non-periodic order in the arts. Xenakis, while working as an engineer in Le Corbusier's office, was responsible for the design of the undulating glass panels at the facade of the monastery of St Marie de La Tourette. Four one-dimensional tiles in golden proportion and their combinatorial distributions were the constructive units. [10] At the same epoch he employed Fibonacci series to organize the temporal sections in *Metastasis*, a work based also on ruled surfaces in the form of continuous massive glissando structures. The idea of transforming graphics into sound was elaborated by Xenakis at the UPIC system in the late 1970's.

Aperiodic order is present also in the design of more recent architecture. Penrose tilings, with tiles appearing in ten different orientations, are used in the Royal Institute of Technology RMIT and the pin-wheel tiling, with tiles appearing in all rotation angles, in the Federation Square buildings, both in Melbourne, Australia. Obviously in many cases, the use of patterns with interesting mathematical properties does not necessarily give results aesthetically appealing.

From a mathematical point of view, the appropriate space in pattern analysis is not the original surface but a folded version of it which is called the orbifold. [1] The set of points of the same kind is called the orbit of the symmetry group and the folding takes all the points of the same kind to a single point. Repeating patterns can be folded into an orbifold on some surface. The description of manifolds in two dimensions is often done by identifying some edges of simpler surfaces. Deterministic and random aperiodic tilings in two and three-dimensional manifolds have been presented in the past few years (see [5] and references therein).

There are several methods for constructing aperiodic tilings: cut-and-project methods, substitutions and matching rules. Substitution tilings grow by iteration of a set of inflation rules applied to a given set of prototiles. A tiling space can be seen as the set of tilings that locally look like translates of a fixed tiling. For the analysis of the cohomology of tiling spaces a type of cell complex is defined. [9] For each particular case the complex contains a copy of every kind of tile that is allowed, with some edges identified, and the result is a branched surface that can not be represented properly in three dimensions. A way to get an idea about it is to generate a pattern where the basic polygons with the same shape, color and orientation represent the same tile in the complex. [7] The topological interpretation is that if somewhere in the pattern a tile shares an edge with another tile, then those two edges are identified. The goal in the geometric representation is to visualize in some way the space unfolded without need of supplementary dimensions.

In the visual and sound arts, this type of constructions have potential interest as a system of reference in constrictive preforming for channeling the expressive energies.

2.-A branched surface associated to an octagonal tiling space.

In a substitution tiling the pattern obtained after applying n times the inflation rules to a given prototile is called a level- n supertile. A substitution is said to force the border if there is a positive integer n such that any two level- n supertiles of the same type have the same pattern of neighboring tiles. Tiles labeled by the pattern of their neighbors are called collared tiles. When the substitution does not force the border, collared tiles can be used for the study of a type of topological invariants known as Čech cohomology groups. [9,7] In what follows I discuss how the procedure is applied to one of the octagonal tilings introduced in Escudero. [3] The study of its cohomology motivates the generation of colored aperiodic tessellations which represent branched surfaces. [6] In contrast to other well-known octagonal examples with the silver mean as scaling factor, like the Ammann-Benker patterns, this substitution does not force the border.

A vertex configuration is a set of tiles sharing a vertex. The first step in the construction consists in analyzing the dynamics of the vertex configurations. The tiling has the property of finite local complexity, which means that for some positive real number R , the tiling contains, up to congruence, only finitely many local patches of diameter less than R . Also it is uniquely ergodic, namely, it has well defined patch frequencies. In general after n inflation steps all the vertex configurations are transformed into a finite

subset. In this case it is formed by just two vertex configurations. This is the set of vertices taken to form the cell complex.

The tilings with eight-fold symmetry in [3] have four triangular prototiles represented by the letters A,B,C,D. Their edge sets are: A(a,b,b), B(g,d,e), D(g,b,b), E(b,b,z), where a,b,g,d,e,z represent the edges having lengths $2c_1, 1, 2c_2, 2c_1c_2, 2c_2c_3, 2c_3$, respectively, with $c_k = \cos(k\pi/8)$.

Iteration of the inflation rules applied to a given prototile shows that there are, up to mirror reflection, forty-one vertex configurations. After four inflation steps all of them are transformed into just two, that we label 1 and 2. This can be seen in Fig.1, where the superposition of two patterns separated by four inflation steps is shown. The vertices transform into themselves under the application of the inflation rules: $1 \rightarrow 1$, $2 \rightarrow 2$. In Figs.1 and 2 we can see both: the vertex 1 has star shape with sixteen A-type prototiles (blue), and the vertex 2 has ten A-type (eight of them yellow-green) and two of type D (green).

The edges and tiles appear in eight different orientations. By analyzing level-4 supertiles, we get the sets of possible collared tiles and edges. Having in mind the different edges and vertices we can construct a cell complex which contains 25 collared prototiles, up to mirror reflection and orientation. In order to distinguish the prototiles with the same shape we assign them colors. More than one hundred colored vertices from the forty-one initial vertex configurations appear. A fragment of the pattern representing the corresponding branched surface can be seen in Fig.2.

The collared pattern can be described in terms of formal language theory, more precisely, with the help of Lindenmayer systems. [3] The words characterize the tilings in a unique way. The word production rules are defined with the intention to describe finite patterns by word sequences as a kind of symbolic dynamical system, which is very "natural" in one dimensional substitutions like the Fibonacci sequence. In one dimension if two letters appear consecutively then the corresponding tiles appear together in the geometric representation. In order to generalize this to two and higher dimensions one has to introduce a bracket structure and the letters in the alphabet represent oriented prototiles. The allowed words in the formal language then are of the type $((ABC)(FA)(DE))$. The geometric interpretation is as follows: A and B appear together in the word and there is only one way to "glue" the corresponding oriented tiles edge-to-edge. The same applies to the supertiles represented by (ABC) and (FA) or to $((word1))$ with $((word2))$... if they appear consecutively in a given word (notice that C and F will not appear, in general, adjacent in the geometric structure). A bracket belonging to the alphabet has to be interpreted not as a tile, but as a way to group tiles to get supertiles. The use of brackets mimics the hierarchical structure and it seems that they are not avoidable (without losing the result that if two letters representing tiles appear consecutively then the corresponding tiles can be glued in only one way). The model has the advantage that can be applied to higher dimensions as well.

3. Concluding remarks

In the construction of the cell complex another point of interest is to analyze the ways color can interact with the symmetries of the pattern. For a discussion of the mathematics of color symmetry see. [1] Here there is a freedom in the color selection and the final results can be very different, due to the emphasis in distinct geometric substructures. When we take into account the set of the patterns obtained by all the possible color selections we are approaching to a metaphor of the concept of rhizome which is made of plateaus. Each pattern would be an image of a plateau or "continuous, self-vibrating region of intensities whose development avoids any orientation toward a culmination point or external end." [2] Also

each pattern is related to any other pattern and can be generated starting in a limitless number of ways. There is a principle of connection and heterogeneity in the sense that any local geometric configuration appears in some other place, in fact, in infinite places when the plane filling structure is considered. The pattern is made of lines and occupy all the dimension of a “plane of consistency” following a principle of multiplicity. Each plateau here would have a strong principal unity of root-tree type because its generation is the result of successive iteration of a large set of inflation or substitution rules in a Lindenmayer system. However the whole set of colored patterns does not have this arborescent characteristic.

The basic symmetries are continuously broken and have to be perceived in a dynamical way as would be the case if temporal phenomena were embedded. There are also various levels of perception depending on the distance of observation. The image can then be seen as a kind of nomad place. While we contemplate it we travel through a space in constant change, where local configurations of just four shapes, like a ritornello, always reappear but in different surroundings. This property is preserved when we extend the pattern to infinity, but we can have a sensation of it by observing a finite fragment.

The simplicial arrangements of lines given in [5] are the basis for the derivation of non-periodic planar tilings with any symmetry. The analysis of their associated topological invariants provides a rich source of branched surfaces generation. In addition, certain families of simple subarrangements can be used for the construction of algebraic surfaces with many nodal singularities that can be represented in 3D. In Fig.3 it is shown a work based on a surface corresponding to a polynomial of degree nine obtained from one of the arrangements with 18 lines in [5] and containing the seven prototiles of a series of tilings introduced by the author in 1998. It has cyclic symmetry and 220 real nodes.

In the time domain, substitution tilings and their appearance in the field of astronomy have been on the basis of the formal procedures in several instrumental, vocal and computer generated works, where time harmonizations and sound synthesis derived from spectra of aperiodic ordered sequences play a central role. [4] One of the pieces where this techniques are present is *Yod*, for 6 percussionists and computer, performed by the austrian group Studio Percussion Graz at the 2005 ISCM World Music Days in Zagreb. On the other hand certain identifications leading to quotient spaces and orbifolds have been commonplace in musical practice. A recent work, where this and other concepts of combinatorial topology are explored as part of the precompositional materials is *Los límites móviles del agua* for two pianos, which the Ensemble Surplus plans to perform in Freiburg, Germany.

Both the visual and sound works must be regarded as projections from the same rhizomatic space. They are just manifestations of some of its infinite plateaus.

HYBRID ART FORMS: THE WAY OF SEEING MUSIC

BILGE EVRIM ERKIN

This paper will focus on relationship between music and visual arts through the idea of hybrid art forms. Within this interdisciplinary approach, it aims to consider scientific and technological developments and the way its effects on art and perception. In this context, examples by some of hybrid art forms will be analyzed and finally compared with recent multi-media works.

Throughout the Ancient times, from Aristotle to Schopenhauer, from Pythagoras to Newton, common aspects of vision and hearing have been taken account as an interesting research field. In his passage *De Sensu*, Aristotle remarked the correlation between sound and color by encompassing physical and perceptual matters: "We may regard all these colors (all those based on numerical ratios) as analogous to the sounds that enter into music, and suppose that those involving simple numerical ratios, like the concords in music." [1] However, the analogy in physical relations between sound and vision were grounded to the ideas of Pythagoras who had depicted the musical sensory qualities related to mathematical ratios.

At the end of 18th century, physical correlations of harmonics could have been displayed by the inventions of various tools. For example, Ernst Chladni had produced his patterns with a simple system that included scattered sand onto a square plate. Chladni's patterns were occurred when this plate was bowed in certain notes. [2] Within the 19th Century, the interest of these instruments had gradually increased. French mathematician Jules Lissajous used small fixed mirrors on the sideways of small steel instrument and Sir Charles Wheatstone reflected a light beam on his Kaleidophone to produce the shapes of harmonic vibrations. Among those inventions Harmonograph is one of the well-known device that create figures of harmonic movement of pendulums.

Beside these physical correspondences between visual and acoustic harmonies, there are also remarkable interpretations vary in different standpoints. Goethe's color theory and Newton's observations on physical similarity of musical scales and seven prismatic rays of light had invoked scientific and artistic researches. In one of the early inventions of color transmission instrument 'Clavecin Oculaire', Louis-Bertrand Castel (1688-1757) modified distribution of Newton's visible spectrum and implemented these colors in to his color schema. In the half of 19th Century, new theories and applications were adapted to the instruments, such as Frederick Kastner's invention called 'Pyrophone' which was a type of gas organ and Bainbridge Bishop's device with a small display placed on the top of a classical organ that sound and its related color could be played together. However, the very-best known color organ was Alexander Rimmington's instrument, which was performed in New York, at the premier of Scriabin's 'Prometheus, Poem of Fire' in 1915.

Synaesthesia generates another common state of visual art and music. From late 19th century till the end of second quarter of 1900's, visual artists and musicians got deeply involved with this phenomenon, which is basically defined as a transition of senses. It was practiced mostly seeing the music or hearing the color of sounds. It embodies subjectivity and evokes personal associations. Like Scriabin, his contemporary in visual art Kandinsky was also aspired by this inner sense.

Artistic interpretations

Mathematical nature of harmony in music has always great influence on other art forms, such as visual arts, poetry and even architecture, which could be discussed in a wide range of interdisciplinary perspective. First of all, the sense of order, disorder and the contrast between them alter our perceptual and psychological response. [3] In music, the pleasure of order is established by tonal properties and its analogy in visual arts is indicated by perspective, which represents the vision of nature in harmony. For instance, when the tonal system was broken down by the technique of Schoenberg's twelve-tone system, the harmonic hierarchy was dismissed. This could be seen analogous in the flattened pictorial plane of paintings. However, Donald Mitchell draw a parallel between Cubism and the new architecture, on the one hand, and Schoenberg's method on the other and claim that abandonment of tonality in music and subsequent development of the serial method is well nigh simultaneous with the abandonment of perspective. [4]

Intensive interrelations between music and visual arts began to form art by responding aesthetical needs of the 20th century's worldview. Painters like Kandinsky, Klee and Kupka devoted their art to become unified with the idea of music that has the power to give expression without help of representation. Abstractness, which is considered as an essential property of music became great achievement for visual arts. Latter on, it was also determined by Clement Greenberg, who believed in independence and the purity of modernist art. For Greenberg all arts can pursue the sensuous and physical property of music. [5] Thus, in relation to other arts, music became a model; but the significance is, it should be considered as a method rather than an effect.

Greenberg's modernism is based on distilling art forms and by referring to Lessing and Babbitt; he revealed a long running idea: 'medium specificity.' On the other hand it is interesting that contemporaneously there developed new art forms and innovative experiments based on synthesis of different mediums.

Medium syntheses previously had been seen in the stage compositions like musical dramas and operas and latter in modernist period it gained new inspirations. Like in the 'Yellow Sound' (1909-14), which was an experimental piece, Kandinsky embraced all perceptual effects and blended different art forms. He turned increasingly to music by working on experimental stage compositions with Thomas von Hartmann who used music, painting, dance and lighting in his stage works. At the same time his colleague Schoenberg intensified his painting practices and stated to work on small operas. His short drama 'Erwartung' (1909) and the opera 'Die Glückliche Hand' (1910-13) revealed the same synthetic manner. Contrary to Greenberg's discriminative sense, the synthetic relations of music and visual arts could be seen as influence by Wagner aesthetics: the 'Gesamtkunstwerk' where all arts united under the banner of music.

Although in Greenberg's exclusive sense of modernism or in Wagner's unified art form, music is seen as a paradigm, as a model to define aspired 'modern' art. As Simon Shaw-Miller has pointed out in his essay 'Modernist Music', the modernist conception, has two streams developing at the birth of modernism "which are generated from music." [6] This bilateral condition of modernism stated in on the one hand 'abstract formal techniques' and on the other in 'multi-sensory' or 'multidimensional model', they can be called 'formal modernism' and 'contextual modernism', 'pure' and 'hybrid'.

Within this time period, among these stage experimenters, Thomas Wilfred conditioned himself with an exceptional aesthetic notion. He suggested a new art form, Lumia, the Art of Light, which has only light

as an independent aesthetic medium. With his instrument named Clavilux, he performed silent compositions –which were also given opus numbers like in music - controlled by a keyboard. He stated the aesthetic concept of Lumia as “The use of light as an independent art-medium through the silent visual treatment of form, color and motion in dark space with the object of conveying an aesthetical experience to a spectator.” [7] In 1920’s, when Thomas Wilfred began his experiments with Clavilux, some other artists saw advantages of film as a medium to express their abstract context. Oskar Fischinger, Walter Ruttmann, Hans Richter and Viking Eggeling, they all became aware of potentials in forth dimension. Their formalist tendency in abstract experience has broadened the essential meaning of composition, rhythm, color and the form.

It is reasonable that not all art forms are pure. Jerrold Levinson defines hybrid art forms as “art forms arising from the actual combination or interpenetration of earlier (existing) art forms.” [8] Then he goes on to categorize hybrids as juxtapositional (additive), synthetic (fusional) and finally transformational in which visual music –in the form of abstract color film- is considered as. But for Levinson, because of the transformation of music (western classical music) into abstract film is not structurally and thematically possible therefore he claims visual music as a nonexistent art form. Nevertheless he mentions that these kind of nonexistent art forms could someday exist “by appeal to radically new means and media that technological advance will make available.” [9]

LIGHT ART IN PUBLIC SPACE

Titia Ex

Since 1991 light artist Titia Ex, has examined the value of light art in public space: its symbolic significance, referring to spirituality or the triviality of modern society. Light is a transfer of energy, an infinite potential of relationships that permanently engenders new links between things and people. Light can dematerialize public space architecture, where limits only exist on the face of things, and dissolve fixed movement patterns.

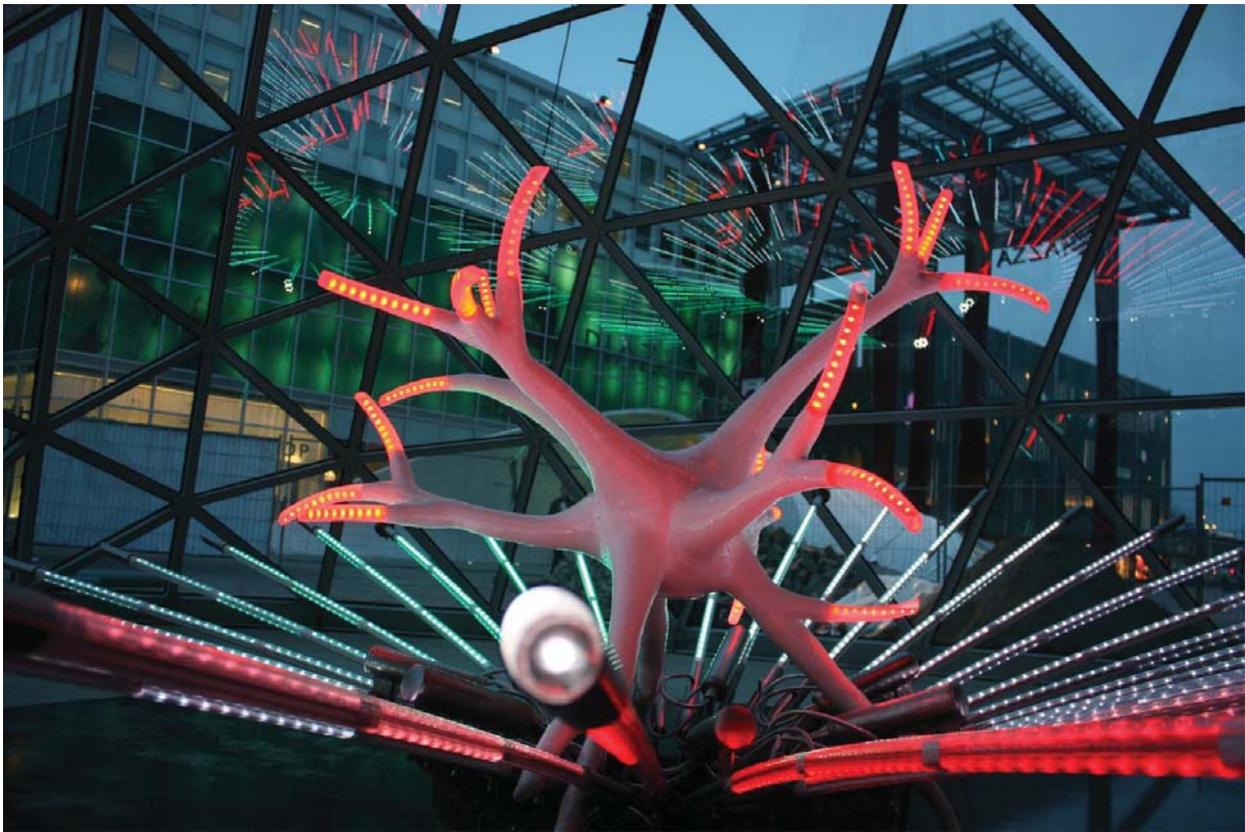

Fig 1. Flower from the Universe, 2010, Titia Ex, interactive light installation, led, diameter 17 feet, photo: Titia Ex.

Fig 3. Halo, 2010, Titia Ex, neon, diameter 13.1 feet, Utrecht, photo: Merijn van der Vliet.

In this paper, I would like to examine the value of light art in public space by focusing on my own practice-based field as a light artist. To me public space is a living organism. Public space is not a saturated or static space but an expanding area. The ever-changing environment has a huge impact on human behavior, on our values and our (inter) actions.

Art in public space can mirror this continuous process of interaction between people and their environment. It can draw the environment from its anonymity and establish different, new and unexpected connections, creating new perspectives on space and time and adding new relational experiences. Light

has a huge symbolic significance: it can refer to happiness, spirituality and enlightenment as much as to the triviality of modern consumer society. [1] Light art includes both artificial and natural light. Light uses time and space as material. It has a presence without presence. It doesn't merely draw attention to itself, it gives visibility to space. Light is a stimulus to our skin, body and brain.

When starting my career as an artist, I produced very short films and looped film installations, sometimes combined with slide projections. The films mostly showed inanimate objects that were a luminous presence in the real space surrounding them. They were an investigation of time and motion, often with the projector light incorporated as a visual element. The 16mm film *Still life* [2] for instance, at first shows a dining table where people have eaten. For moments nothing happens; the spectator is sitting in a dark room, looking at the deserted table, becoming impatient, when slowly the image catches fire. Apparently, you were looking at a flat two-dimensional picture of dinner party leftovers. The flat image is burning down, but turns out to be displayed on a real, three-dimensional table. The moment the spectator realizes what is happening the celluloid catches fire. The spectator remains looking at an empty – light – screen (which then turns into black).

A few years later I exchanged the celluloid surface with its accompanying light source for the transparency of glass, thus capturing the ambient light. I made large mobiles and pivoting screens: door-sized glass panels suspended in wooden frames shaped like full-size mirrors. Slides representing a geometric pattern of green dots, a detail of a plant in black and white or pictures of an empty room, images you look at without really seeing, were projected onto the glass panels. The translucent, satin-finish mobiles, consisting of etched glass discs two feet in diameter, reflected or absorbed the light, according to outside influences such as drafts and light changes. A light switch, a sink drain, a coat rack detail, familiar, everyday things you never pay particular attention to, were silk-screened on the surface in two or three colors. The mobiles created interplay between light, movement and space, both directly and indirectly. The projections on the pivoting screens added another layer to my work. Spectator participation comes when movement blocks the light when standing between the light source and the empty screen. Tilting the glass screen alters the projection and creates a reflection of the image on the wall, floor or ceiling, or makes it disappear altogether. There is no point of focus, no center left, only a continual exchange of stimuli between subject and object.

Working with light in public space is working with movement, transparency and time, all in one. It is a quest to find the rhythm - people in motion, contemplative or en route to somewhere else - and how to apply a poetic echo to this rhythm. The work is always in a dialogue with its physical surroundings and is incomplete without it. It joins the space without being absorbed by it. It makes a natural connection between space, material and viewer. Light has the virtue of reflecting on both the skin of the spectator's body and on the body texture of the environment. It has presence and non-presence. It is what the Japanese call *Ma*: the way to sense the moment of movement [3] or a simultaneous awareness of form and non-form. The word *Ma* essentially refers to an "interval" between two (or more) spatial or temporal things or events. Visitors to an exhibition do not look at *Ma*; they are touched by it and installed in it. The subject-object relationship is deactivated.

The space, the setting and the occupants of the space all supply material for the artwork. In *Musical Chairs*, [4] a permanent installation on top of a round building at the centre of a furniture mall, thirteen computer animated neon chairs in different colors switch on and off in a repetitive pattern. Unlike the children's game, it is the chairs that appear to be dancing; especially at night, when the artwork adds a festive, big city-like impulse to the monotonous architecture of the mall. There is always one chair short

in this dance, so the entire piece only exists in the mind of the spectator, who grasps its shape and character by moving around the building.

The Poet is a Cow [5] is a temporary work on the façade of the Dutch Social Insurance Bank (SVB) headquarters. The work, titled after a poem by the Dutch poet Gerrit Achterberg, consisted of a colored foil layer on a large window, representing an enormous light blue cow's head, a dark blue farmer floating in the sky along with his cow, a red and purple toddler, crawling down the dyke, a green globe with a cow's silhouette on its surface. The image relates to the Dutch landscape, flat and sky high, and the cow is a metaphor for the welfare bank. The colored foil introduced the tension of light in this white, glazed building. During the day the sun projected the image into the main hall and colored the office spaces, until the images disappeared due to passing clouds. The light installation dematerialized the space, the building became the canvas and the sunlight acted as a brush. Visitors to the building became part of the predominantly violet light landscape in the hall, and when using one of the glass elevators they became immersed in the huge cow's head. The intervention of the work very gradually affected the people working in the institution. In time, they discovered that the reflection of the colors also entered the offices, coloring their papers and walls. This "color bath" put their environment in a different perspective. People became aware of the physical light and space, and their own movements, and felt more unified with the architecture and surroundings.

Another example is *Halo*. [6] A permanent light circle, diameter 13 feet, floating above the crest of the lower chapel of the Roman Catholic Church Saint Willibrord in the city of Utrecht. The church was built in 1877, a time in the Netherlands when Catholics were again able to express their faith by building new churches. The entrance is humble, in a residential street with small shops, the church disappears out of sight, is invisible. The work of art establishes a link between the church and its surroundings; the silent gesture taking the church out of its shadow. The circle of light – comprising two neon lines, a golden yellow inner circle and a pure white outer circle – is both dynamic and static, it connects the space to a human sense of history. The intensity of the light in the artwork draws your eyes upwards only to disappear into the black hole, experiencing another dimension of space in the city.

Last year I made *The Waiting*, [7] a site specific, computer animated installation during the contemporary music and art festival *Into The Great Wide Open*. 'The Waiting is the hardest part', is a song by Tom Petty, who also wrote *ITGWO*, the festival's title song. The work comprised forty red LED lights that float just below the surface of a pond and blink randomly, short – long – short. The spectator's close attention was drawn by the continuous random blinking; endlessly waiting for a pattern never to emerge, knowing all was there. The unreadable rhythm of this atmospheric lighting evoked a sense of infinity and a sense of life, an effect that is disconcerting and exhilarating at the same time.

This layered thinking in associations and references is a recurring element in my work. Neither the object itself or the beholder is most important, but the very moment at which everything converges. My installations, computer animation works and video loops seek a balance between this elusive border area at the edge of human thinking and a plain understanding. I wish to create a personal, intimate moment, preferably in a dynamic field of the public domain. This notion is strongly reflected in the interactive light installation *Flower from the Universe*. The installation is always in the present, like a real living, biological plant, [8] unfolding the moment.

Flower from the Universe is a gigantic light flower, seeming to float above the surface, with a heart modeled on a nerve cell, encircled by a garland of graceful stems. A circle of seven pods lies under the heart, and in here the seed of movement is hidden. By walking around the artwork, the visitor sets off a wave

of moving colors. The flower records the colors surrounding it and transfers these to the “petals” - group of stems - into which the garland is divided. Near the borders between the petals, the reflected colors gradually fade into one another. The nerve cell in the heart has illuminated offshoots that follow or are in contrast with the colors in the garland. A dynamic interplay is created with both the viewer and the surroundings influencing the light flower.

This object works using sensors and specially developed software that controls the LED lights in the stems and the offshoots of the nerve cell. Without the external stimulus, the offshoots will switch over to internal control. The principle behind it is physical space. Space as a palette, as a biotope: a living organism. The context changes continually, viewer and light sculpture intermingle and connect, and together are incorporated into a unity of time; there is no beginning or end. _

The *Flower from the Universe* has been exhibited at various locations, [9] including a pond in a botanical garden and the hall of an immense “blob”: an organically shaped glass structure designed by Massimiliano Fuksas. At each location I noticed how people responded to the *Flower* and what impact light can have. Using their bodies, mindful of or attentive to their environment. There is no rational model that allows us to foresee how it feels to play and experiment like this with color. The identity of a color does not reside in the color itself, but is established by relationship. [10] Colors present themselves in a continuous flux, constantly related to changing neighbors and changing conditions. In no reliable sense can we speak of color “as it really is”; it is always determined by its context. A diverse public of all backgrounds and ages were fascinated by the chance color of the moment, became absorbed in the work and mingled with other passers-by. They actively collaborated, interacted with each other, played and blended into their environment.

I like the complexity of working with light in public space. Each context is different, changing the perspective of perception and memory. Light can pass borders; it can fill a space in an instant and be gone the next moment. Light can convey both the dynamics of a space and its tranquility. It can establish an intercourse between several dimensions with a diversity of actors, involving the spectator’s sensory experience.

The Danish light artist Olafur Eliasson works with sensory experience using natural phenomena. He creates an ongoing exchange of stimuli between the visitor and the space. Like *Your rainbow panorama*, [11] 2006-2011, on top of the Aarhus Kunstmuseum, a permanent elevated structure with a 360° view of the city of Aarhus, Denmark. Suspended between the city and the sky, the viewing platform insists on the sensory engagement of those who enter it walking through the colors of the rainbow, from color to color. The USA light artist James Turrell usually encloses his audience in order to control its perception of light and make it lose all sense of space, scale and color, like in the series *Skyspaces*, [12] built at several locations, a number of architectural installations with holes in the ceiling to look through at the sky, meticulously designed in order to heighten the viewer's awareness of light.

The present state can also lodge the past. Currently, I am working on a new temporary project in public space; it is partly virtual and entitled *Walking the Light*. It is about attachment to a place, recollection and transformation. The work draws the public space out of its anonymity and forms different, new, unexpected connections. It will entail walking a light circle in an urban landscape led by virtual light guides carrying torches while telling their stories. It will reflect the public space in a poetic manner, evoking a sense of belonging.

Artificial light is an expanding field bearing innovations within the scope of architecture, health care, and the quest for mobile and sustainable light systems. Light facades; the public space; innovative employment of light as a stimulating impulse to our bodies, in light therapy and brain activation methods; mobile light sources, like LED, making it possible to wear light on the body; and sustainability solutions, allowing spaces to be lit in a cost-neutral way.

Art reflects who we are, and what really matters to us. Light art in public space doesn't begin and end in a physical frame. Light is a transfer of energy, an infinite potential of relationships that permanently engenders new links between things and people. With light you can dematerialize the architecture of public space, where limits only exist on the face of things, and dissolve fixed movement patterns. Public space, not as a passageway, but as the place where life is lived, amidst historical tokens, rediscovering or redefining the environment from a new dynamic perspective. Light art can contribute to the present, to the relational experience of a place, to a general consciousness of being in a public place. The Dutch poet Rutger Kopland interprets this exquisitely as *An empty place to stay*. [13]

ART, TECHNOLOGY, AND INSTITUTIONAL DISCOURSE

Jill Fantauzzacoffin

This paper and talk ties together current innovation policy initiatives that incorporate the arts into their programs, before arguing in support of more complex understandings of the relationships between art and technology.

Recent structural changes in Western industrialized economies include the establishment of the knowledge economy, competition from emerging nations in the manufacturing sector, economic crises, and grand scale challenges such as climate change. National leaders are seeking to support the development of new economic sectors as a response to these circumstances. This has led to a focus on innovation economies fueled by increasingly rapid technological change. In this climate, creativity and technological innovation are seen as correlates to a competitive economy. At the same time, art has shown its capacity to engage with high technologies through a critical mass of technological art visible in exhibitions, public interventions, symposia, and specialized academic programs. This paper ties together current innovation policy initiatives which incorporate a spectrum of roles for artists. It then argues in support of more complex understandings of the relationships between art and technology.

European Innovation Policy

Millennial European Union (EU) innovation policy exemplifies the shift from conventional technoscientific industrial research and development (R&D) initiatives to those incorporating a focus on creativity as a driver of innovation. In March 2000, at the EU Heads of State and Government meeting in Lisbon, national leaders set an overarching goal to make the EU “the most competitive and dynamic knowledge-based economy in the world, capable of sustainable economic growth with more and better jobs and greater social cohesion” by 2010. [1] The policy supporting this objective is known as the Lisbon Strategy. One of the main goals of this ten-year economic plan was for government, university, and corporate R&D spending to reach 3% of gross domestic product in each of the member nations. Throughout the first half of the Lisbon Strategy years, we see strategic guidelines, such as the communication *More research and innovation*, [2] which correlate economic objectives and institutional R&D. The shift to a rhetoric emphasizing *creativity* and innovation in addition to institutional R&D is apparent in the 2008 Council of the European Union communication, *Council Conclusions on Culture as a Catalyst for Creativity and Innovation*. [3] Here the Council promotes a broader understanding of innovation and recognizes the contribution of the arts and culture to foster creativity. Overall, EU communications throughout the decade 2000–2010 show a shift from institutional R&D toward a vision of an innovation economy emphasizing creativity as a key resource in the new economic environment.

This change in the concept of innovation is due in part to a shift in profitability from the manufacturing sector to the creative industries. While traditional manufacturing industries in Western countries suffered external shocks such as the rise of industry in emerging nations, the knowledge-based creative sectors were resilient. According to a 2010 United Nations report, despite the 12% decline in overall global trade, world trade of creative goods and services increased by 14% between 2002 to 2008. [4] A recommendation in the same report suggests that “Policy strategies to foster the development of the creative economy must recognize its multidisciplinary nature — its economic, social, cultural, technological and environmental linkages.” Here the ‘creative economy’ refers to a loose intersection of the arts,

culture industries, business, and technology, particularly digital technology. In this thinking, economics are explicitly linked with creativity, technology, and human social and cultural development in the sense that the ability to create and circulate creative intellectual capital can produce income, jobs, and export earnings. Artists working commercially in the creative industries are typically configured as contributing aesthetic assets, whether it be digital assets, storytelling, music, or product design, for example.

The later Lisbon Strategy years saw the 2008 economic crisis as well as the European Year of Creativity and Innovation, 2009. The role of this initiative was to highlight innovation and creativity as a response to the global downturn. Prioritizing creativity and innovation in conjunction with the knowledge economy represents a transition from the mindsets, practices, and divisions of labor that determined success in the industrial economy toward an economy where creativity, entrepreneurship, knowledge resources, skills, and expertise function in an interconnected, globalized economy running on a combination of information and know-how.

The shift in policy rhetoric from industry-focused research and development to creativity-fueled innovation brings the arts into innovation discourse. In preparation for Europe 2020, the next European economic framework following the Lisbon Strategy, 75 experts at the “Towards a Pan-European initiative in support of innovative creative industries in Europe” workshop, wrote the Amsterdam Declaration of 5 February 2010, which stated:

Beyond their contribution to cultural diversity, creative industries represent indeed a great economic and social potential. In order to take full advantage of this potential, there is a need to combine arts and creativity with entrepreneurship and innovation. These industries are not only a source of inspiration but represent also an enormous asset to be turned into competitive advantages and the creation of new and better jobs in Europe. [5]

The relationship between the arts and innovation in this discourse is supported in part by the associative relationship between the arts and creativity, and creativity and innovation. Other discussions of the role of art in innovation policy configure “humanistic” contributions of the arts:

Art and culture can make a vital contribution to the achievement of objectives that reconcile wealth creation with sustainability and respect for common humanist values because one of the features of art and culture is that they help us to transcend purely economic or utilitarian constraints. [6]

In these examples we can see various configurations of the artist within the new innovation initiatives. Many of these initiatives situate artists in terms of potential aesthetic, creative, and humanizing contributions to the central project of technology development and innovation; however, there are EU-related projects which configure artists as more centrally involved in the development of technologies and innovation processes. For example, INNO-Grips is a project of PRO INNO Europe, a research agency that supports European policy. Their report titled *Innovation Unbound: Changing innovation locus, changing policy focus* positions artists in multidisciplinary innovation labs along with engineers, architects, designers, sociologists, businessmen, and policy-makers. [7] INNO-Grips sets forth a vision of a network of multidisciplinary and interdisciplinary innovation labs supporting Europe as the “global innovation leader in effectively addressing complex social, environmental and economic challenges through sustainable, human-centered and democratized innovation.” In this vision, these innovation labs “create and support the combination of social, scientific and artistic disciplines.” [8]

Two programs existing independently of the EU policy framework also place artists centrally within the innovation team. Disonancias is a Basque organization supported by the corporate Xabide Group and the Basque government. Disonancias places artists in companies, research centers, or public institutions to work along with members of these organizations on innovative projects. Disonancias promotes the capability of artists to “propose new and different innovation paths, introducing detours and dissonance into the usual processes of thought and action.” Disonancias puts forth the view of artist-mediated innovation “not as an end in itself, but as a tool to change ways of acting, attitudes and values, beyond that of economic benefit.” [9] Disonancias was chosen as a Best Practice Case in Creativity and Innovation by the European Year of Creativity and Innovation program.

AIRIS is a similar project initiated by TILLT, an organization formed by the region of West Sweden in 1973 as a platform for collaboration between artists and businesses. Under AIRIS, artists join a company for ten months of collaborative project work. The AIRIS project has three main goals: “to create an interface for interaction between industry and the culture sector, to enhance the creative capabilities of industry with regard to a specific business development goal, and to create new employment opportunities for professional artists.” [10]

Creative Clusters

Creative clusters are cities or regions that combine related industrial, small business, or other economic practices. The notion of a creative cluster leverages the idea that through networking and cross-pollination, a creative cluster can be synergistically greater than the sum of its parts. Localization and sense of place are central to the notion of creative clusters, and cultural and artistic presence within the cluster is seen as desirable for community-building. Discourse and initiatives supporting creative clusters configure a spectrum of roles for artists. For example, Digital Media City in Seoul, Korea was established by the city of Seoul on the site of a massive landfill to be the center of Korean broadcasting, music, film, computer game, e-learning, and other digital media-based industries. Commercial artists are employed by the digital media industries, and fine artists are commissioned to create public art. The rationale behind welcoming artists and allocating resources for public art is to support placemaking. [11] The presence of art and artists is considered to play a role in creating an environment which attracts a mobile, highly-educated, and skilled workforce. [12]

Kortrijk, Flanders has a long history in the textile industry. Rather than face economic decline when textile manufacturing moved to Asia, Kortrijk reconfigured itself as a cutting edge design region, Designregio Kortrijk. Thanks to funding in part by the City of Kortrijk, a large abandoned textile factory is being transformed into Buda Fabriek, a physical location as well as project platform for artists, designers, research institutes, students, and businesses to come together and share knowledge about artifact development, new materials, and innovative applications. Supporters see Buda Fabriek as necessary physical infrastructure to create a substantive intersection between artists, the economy, innovation, and development. The goal of Buda Fabriek is to make its locale, Buda Island, into the cultural and artistic node of Kortrijk, thus building a creative cluster within a creative cluster.

Silicon Valley in the United States is often cited as an example of a successful creative cluster. While Silicon Valley innovation depends in part on the dense concentration of technology specialists who can readily interact with each other, there is a parallel cluster of technological artists. Formal contact between artists, scientists, and technologists has come through artist-in-residence programs at Xerox

PARC, Interval Research, the University of California at Berkeley Space Sciences Laboratory, and the Exploratorium, a San Francisco science museum. Informal cross-pollination occurs between Silicon Valley and nearby San Francisco Bay Area artists and technologists through festivals such as the Zer01 San Jose Biennial and Maker Faire, an annual art, engineering, science, and DIY (do-it-yourself) exposition and networking event. There are accessible and well-tooled community workspaces for both technology and technological art projects. These include The Crucible, NIMBY (acronym for Not In My Backyard), and TechShop. The Burning Man Arts Festival, in which 50,000 participants come together for a week each year to build a city in the Black Rock Desert of Nevada, features a high concentration of high-tech art projects from Silicon Valley and the San Francisco Bay Area. Black Rock City, likened to the temporary autonomous zone (TAZ) of Hakim Bey, is itself a creative cluster. Artists and technologists build and test hybrid art/technology projects in the harsh but Dalí-esque desert, exemplifying a mixture of artistic creativity and technological innovation. The Burning Man organization and spin-off affiliates apply this know-how to not-for-profit community art/technology/building projects in public art, disaster relief, K-12 education, and solar energy.

Initiatives in the United States

While the European Union develops pan-European arts and culture policies, there has not been a great deal of interest in the United States in formulating arts and culture policies at the federal level. The largest share of government support for the arts and culture is typically provided indirectly through tax concessions which encourage individual and corporate giving. [13] Yet in 2003, the National Academies Press of the United States published a book titled *Beyond Productivity: Information, Technology, Innovation, and Creativity*. The book argues for institutionalized support for integrated art and technology practices, included under the term 'ITCP' for 'Information Technology and Creative Practices.' The book views certain "art and design practices as forms of computer science research and development." [14]

This book was followed up by a program at the U.S. National Science Foundation (NSF) called CreativeIT, which funded work at the intersections of art, music, performance, design, creativity research, and information technologies. The CreativeIT program in turn led to the first joint meeting of program directors and high-level representatives of the NSF and the National Endowment for the Arts (NEA). This joint meeting produced a roadmap for developing and supporting integrated art, technology, and research strategies at the national level. [15]

These developments intersect with current discourse within and beyond the NSF to expand some STEM (science, technology, engineering, and mathematics) educational programs to STEAM (STEM plus arts) programs. STEAM discourse had been an undercurrent in education, science, and technology circles until recent momentum from the NSF CreativeIT program and the joint NSF-NEA workshop described above. STEAM was given further impetus through a NSF five-year joint research award to Brown University, the University of Rhode Island, and Rhode Island School of Design, a prominent art and design school, to study the effects of climate change on marine organisms and ecosystems. Recently, U.S. Congressman James Langevin from Rhode Island introduced federal STEM to STEAM legislation, which as of the writing of this paper stands in committee. [16]

A handful of public universities in the United States have combined arts and technology programs which exemplify STEAM, including the CADRE program at San Jose State University in Silicon Valley, the Univer-

sity of Washington's DXARTS program, and Arizona State University's Arts, Media, and Engineering program. The prestigious art academies Art Institute of Chicago and Rhode Island School of Design have arts-based research and technology programs.

Art?

As we can see from the examples above, the arts hold a spectrum of new economic potentials beyond the art market, commercial arts, conventional art-in-education programs, and other domains in which artists traditionally participate. Emerging roles include the development or co-development of new technologies or innovation processes within business contexts, participation in creative clusters, and participation in STEAM-based education. Yet within the high status discourse of technology, innovation, and creativity, there are questions regarding the terms of participation. We may be reminded of Adorno and Horkheimer's critical stance toward the culture industries in the mid-20th century, and Benjamin's counterpoint.

To Adorno and Horkheimer, art's function is to challenge the alienating capacity of advanced capitalism. The culture industry brings the 'administrative rationality' of industrial production into arts practice and consumption, thus undermining its ability to challenge the economic hegemony. [17] Benjamin believed that art could participate technically in the same methods that support the culture industries but would invert their purposes to bring about new collective modes of production and participation that undermine the hegemony's ability to create status through a logic of aesthetics (as Hitler had aestheticized war in the 1930s and 40s). [18] These positions regarding the culture industry have parallels in the contemporary innovation industry. The innovation industry values the rapid expansion of the technological frontier. There is a notion of technological advancement building upon previous successes within a domain. Challenges and provocations are not a central part of this paradigm. Thus art-based intersections with technological innovation may be characterized in terms of their formal aesthetic value, expressive potential, communicative power, or humanizing insights. Yet we can see that art from the industrial age forward has a history of radical departures from the established norm, bringing about a reorientation or, to use a stronger term, destabilization of convention, perception, and/or established ways of doing or being. Consider the modern and postmodern works of art we value from the past: the work of the Impressionists, the Cubists, and the Fauves, the writings of James Joyce, the interventions into the concept of art by Duchamp, Warhol, Serrano, Koons, and Hirst. Contemporary Western society does not so much cultivate art that harmoniously stabilizes a practice, concept, or perception. It cultivates art that destabilizes.

In contrast, technological development values stabilization. The practice of engineering is to stabilize natural forces so that they act reliably within a device. This emphasis on stabilization extends beyond technological reliability to social and cultural stabilization as well, so that when we are acting within a reliable threshold of a technology, be it a bridge or an iPhone, we are also stabilizing reliable cultural practices. Postmodern technological art acts outside of these reliable thresholds. Thus it follows that art, as we as a society have conceived it, would not be instrumentalized into the service of status quo technological innovation. Instead, art would be more apt to push and pull on the assumptions of technological development as well as particular technologies and technological practices. This role is already realized by some elements in the art and innovation arena, including Disonancias and Tiltt's AIRIS program mentioned above. We can find further support for this way of understanding art's role in the new innovation economy. For example, President of the European Commission José Manuel Barroso's response

to Culture Action Europe's *We Are More* campaign shows an openness, at least rhetorically, to this conceptualization of art:

Sometimes we can have creative disruption, but it is from this kind of disruption that we can have real construction and also innovative thinking inviting us to prepare for the future in a mindful way. And in challenging times such as this, creative, critical thinking is more essential than ever. [19]

Conclusion

Truly incorporating art and technological innovation practices means admitting the dynamics of stabilization and destabilization within the discourse of innovation. By allowing art to be a churn in the system instead of a well-behaved contributor to sunny-day scenarios of creativity and innovation, we open up new dialogues about what technology is and can be. Such dialogues would come as institutions face the challenges of climate change, financial crisis, increasing competition for resources, and a generation of innovations involving populations existing beyond first world commercial agendas.

SOFT COMPUTING: FORMS AND LIMITS IN COMPUTATIONAL AESTHETICS

M. Beatrice Fazi

This paper contends that soft computing can help us investigate the aesthetics of digital computation. Employing broader conceptions of aesthetics and perception, and whilst drawing upon the ontology of Alfred N. Whitehead, it uses soft computing to address the 'prehensive' dimension of the quantitative procedures of computation, and explores the interrelationship between the factuality and formality of computational structures.

This paper will argue that soft computing may be of relevance to the field of computational aesthetics. By focusing on the theoretical foundation of aesthetics in computation, I will show that soft computing can highlight the indispensable role played by abstract processes within the construction of experience.

Soft computing is a rapidly advancing area within computer science. It is characterised by an attempt to deal with uncertainty, approximation, randomness, and partial truth, and some of its most prominent examples include neural networks, fuzzy logic and evolutionary computation. 'Soft' techniques differ from traditional computing as they employ diverse methodologies in order to cope with the difficulties involved in achieving and maintaining algorithmic efficiency. Their originality and appeal lie in their ability to provide inexact, indeterminate and generative solutions to 'computationally hard' problems (i.e. questions that are too complex to be addressed via classic computational systems).

I will contend that soft computing can offer a means of investigating the aesthetic dimension of digital computation. However, 'aesthetics' will be understood here in a manner that exceeds the disciplinary bounds of a theory of art or beauty: in keeping with its etymological roots ('aisthesis'), it will be taken to denote a theory of relationality and perception. One further qualification: 'perception' will not be viewed as referring solely to human cognitive faculties. Just as aesthetics will be understood in a non-anthropocentric sense, so too will perception: it designates the ways in which experience is constructed, thus referring to the manner in which we encounter things and to the ways in which these things encounter others in turn. Consequently, 'prehension' may be a more appropriate term than 'perception.' I take this suggestion from the work of the philosopher and mathematician Alfred N. Whitehead, within whose ontology prehension plays a special role: it refers to the most foundational type of relation – the extrasensory awareness that all actualities have of earlier and future occasions – and is used to explain how all entities within the realm of actuality are acts of experience. Such experience is not the exclusive domain of human consciousness. All actualities are in fact held to experience one another, whether they are conscious or not, as the data that they inherit from past occasions leave them internally connected.

[1]

Whitehead's ontology and the broader notions of aesthetics and perception that I have drawn from it allow us to view computational structures as possessing a relational dimension that exceeds both their phenomenal effects and the intentionality of their users. My contention is that computational structures can be understood as systems of actual occurrences: they are concrete 'facts,' fully realised actualities, particular to their own spatial and temporal occasion. To focus only on the performative and qualitative character of these events, however, is insufficient. In my view, factuality itself is enabled by levels of quantitative, logico-mathematical abstraction. In a computer science context such abstractions are

usually understood as computing's *modus operandi*: those methods or processes that follow a well-defined procedure and describe how a task is to be performed. Yet I would argue that logico-mathematical abstraction also constitutes the 'form' of computation itself, i.e. its potential character, the pattern that defines its ontological possibility. My interest here is in presenting computational structures both as facts (actual instances, events) and as forms (patterns of potentiality). The aesthetic relevance of computation, in my view, lies in the irreducible relationship between the two. I will show that soft computing practices emphasise this interrelationship of fact and form, and thereby highlight crucial, although largely unaddressed, issues within computational aesthetics.

The relevance of this approach can be illustrated by looking at current understandings of computational aesthetics, but in order to do so I need to make a brief qualifying remark on digitality. Computation and digitality are by no means synonymous, yet both can be understood as processes of discretisation: computation, by virtue of its axiomatic character, involves the discretisation of procedures; likewise, digitalisation can be seen as the technological automation of those discrete procedures. I will focus on the discrete aspects of both computation and digitality below, as in doing so we can underline the fact that contemporary computational aesthetics has overlooked the prehensive dimensions of quantities.

This is important, as the concept of prehension affords a relation between the discrete and the continuous that has eluded contemporary computational aesthetics' attempt to connect the digital to the analogue. Media and cultural theorists, computer scientists and philosophers still disagree on an exact definition of digitality, but they do seem to view the digital as a discrete data technology that uses discontinuous values to access, represent and manage information. Yet, at the same time, the vast majority of philosophical, cultural and social accounts of aesthetic experience portray a universe of percepts and perceivers, the reciprocity of which is established by a rapport of continuity with what is given in experience. Hence the difficulty that digital aesthetics seems to be faced with: where the digital tends to be understood in terms of the discrete, aesthetics tends to be understood in terms of the continuous, or the analogue. The discrete nature of numerical and data quantities is thus largely omitted from aesthetic considerations of the digital medium. These accounts are often geared towards analysing its perceptual, performative, and phenomenical effects, which are possessed of characteristics often associated with the analogical. Codes, scripts, values, parameters and algorithms are viewed as performing actions, which in turn exhibit qualities and properties. Agency and quality thus appear to be key to the disclosure and employment of the aesthetic value of computation. These approaches risk dismissing the mathematical and logical nature of computational digital media. If the latter is specifically addressed, it is done so in a manner that understands the ontological power of logico-mathematical abstraction only in terms of continual calculation; this tends to be characterized as 'topological' in nature and expression, and flattened onto a plane of differential transformability. I, however, would like to propose that the impasse between continuity and discreteness could be re-thought in the light of the prehensive dimension of computational structures, as prehension exists before and beyond any performance, action, or effect. The approach that I am arguing for would retain the possibility of working with the reality of algorithmic entities by addressing the aesthetic dimension of their quantitative, discrete procedures.

Soft computing can help us explore these issues, for it serves to highlight that the rules and quantities of algorithmic construction are always involved with patterns of potentiality, and that these patterns are themselves expressed by abstract logical processes. It thus illustrates the importance of the interrelation of factuality and formality within computational structures. There are a number of ways to prove this speculative hypothesis, but I will attempt to do so here by looking at the empirical and rational characteristics of soft computing methodologies.

As noted at the outset, soft computing uses uncertainty and randomness to solve problems that humans are adept at, but which classical computational methodologies struggles with (face recognition or linguistic disambiguation, for example). Whilst indeterminacy is considered undesirable in the classic theory of computation, soft computing exploits it in order to obtain tractability, lower solution cost and a certain economy of communication. The metaphoric ‘softness’ of this approach is meant to afford an alternative to the ‘rigidity’ of the conventional analytic methods that found the classical theory of computation. Soft computing can thus appear more tuned to the ‘empirical’ levels of reality than traditional computation, as it seems to allow factual chance into its algorithmic formality. This point is perhaps proved by its ability to solve tasks that involve information gained from or modified by experience, such as the industrial application of intelligent systems geared towards solving ‘real life’ tasks (e.g. control, modelling and simulation). Soft computational systems have also been utilized in social science contexts, where adaptation to imprecise judgment, sense perception and emotion is key.

Generative algorithms provide an example of soft computation’s relation and frequent association with the empirical. Chance, I would contend, is particularly important for generative algorithms, as they encode formal rules via the application of a bottom-up approach designed to encompass contingent change over time. The programmer deliberately writes very simple instructions, and lets complex behaviour emerge through an iterative selection process, which picks the best representations of solutions, rejects bad results, and produces new ones from those that survive the procedure. Generative algorithms are therefore able to modify their own code, allowing new combinations to arise from parallel and random behaviour, and thereby simulating natural selection and biological evolution. [2] This process fosters autonomy and uniqueness, and has in consequence been employed by artists as a means of playing with the underlying rules of formal generation and structure. It however also offers an interesting prompt for us to speculate as to the ways in which empirical factors – in the guise of variation, selection and evolution – can enter the formalism of computation.

The example of generative algorithms illustrates that soft computing can be seen to be characterised by an empirical aspect. Yet this does not mean that soft computing dismisses logic and formality: where others have emphasised its orientation towards the empirical, I would argue that its most interesting theoretical implications lie in its indirect continuation of what might be called a ‘rationalist’ project of optimization, compression and synthesis.

My point is that soft computing, despite its openness to contingency, still operates within the rational, disciplinary bounds of mathematics and logic. This can be seen in fuzzy logic systems. Whilst the traditional method of computation uses binary logic, which permits only a dichotomous opposition of true and false, fuzzy systems compute via a logic that allows for differing truth values: they are thus able to reflect the imprecise definitions of language, and can engage with complex control, management and recognition problems that cannot be framed in ‘crisp’ terms. The fundamental idea behind fuzzy logic is that all things exist in degrees, and that we are in consequence bound to encounter imprecision in truth. Fuzzy logic responds to this (as does the seminal fuzzy set theory first outlined in 1965 by Lofti Zadeh) [3] by trying to tune knowledge representation, so as to make artificial systems function more like humans. Like the generative algorithms described above, fuzzy logic thus accommodates the contingent conditions of experience, but in capturing loosely-defined categories and generalising them it remains a formal model; so too does the generative algorithm, which puts forth a problem-solving strategy in terms of a set of axiomatic rules evolved upon a specific yet formally addressed situation. In sum: although many have associated the merits of soft computing with this orientation towards the empirical, I would argue that it is this formal dimension that constitutes its real potential.

This claim can be developed by looking further at fuzzy logic. The latter is a logical calculus designed to build a formal system capable of handling information devoid of analytic formulation. Fuzzy logic, however, also produces a logico-mathematical structure that can be computed, and which can be put into the finite terms that machines require in order to operate. One can therefore comment that the rationalizing power of soft computation stems from its capacity to enlarge the realm of actuality, through accommodating factors that could not be encompassed by mathematical formalization. Soft computing has consequently been viewed as incorporating a degree of quality into the computational process, as it can be interpreted as a quest to capture the 'continuity' of things through approximation. Imprecision would then seem to arise from a continuum possessed of degrees that can be broken down into 'fuzzy' chunks. One can see how this project can perhaps be associated with the 'analogical' digital aesthetic perspectives discussed above, which frames aesthetics in terms of the continuous transformation of perceptual qualities. Yet, in my view, fuzzy logic is also characterised by attentiveness to the implicit rationality of the real: its focus rests not on binary calculation per se, but rather on the inherent possibilities of calculation itself. Thus, contra those who would claim that the importance of soft computing lies in its attention to quality, I would argue that it returns us to the significance of the quantitative in computational aesthetics.

Fuzzy logic's advocates often emphasise that the technique uses imprecise indicators instead of exact values. However, I believe that if we look at the manner in which fuzzy systems deal with vagueness we are brought back to a question implied by Alan Turing's classical theory of computation, which he set out in 1936: how could one devise an 'effective method' composed of finite terms that might be able to put the infinity of quantities into the finite terms of a procedure? [4] Such a method would be a process of discretisation, as is the method by which fuzzy logic deals with vagueness. Briefly, fuzzy logic works through a system of sets with graded members; each grade is possessed of a different truth value, and each member thus forms part of a smooth but differentiated continuum. One might read this as an attempt to turn quantity (discrete grades) into quality (varied continuity), and to create a means of computation that comes a little closer to 'reality'. However, I would hold that it in fact remains just as reliant upon the quantitative and the discrete as Turing's theory of computation, as soft computing's ability to cope with the uncertain is itself grounded on the quantitative nature of computational formality. Fuzzy logic doesn't render quantity qualitative by attributing continuous characteristics to it: rather, the mathematical processes that allow fuzzy systems to accommodate approximation are themselves based on the procedural and axiomatic modes of quantitative abstraction.

It is important to stress now that the observations above locate soft computing within a broader debate about the limits of formal reasoning. These limits were envisaged by the logician Kurt Gödel in 1931, [5] and subsequently framed in terms of computability by Alan Turing in the 1936 paper mentioned above. Turing's famous thought experiment, the so-called Turing Machine, established the theory of computation by demonstrating that there are limits to what can be computed. His account has however received criticism over the last two or three decades, and much of this has involved framing his model as a closed formalism that doesn't allow for the influence exerted by the external factors of contingent reality upon its purely internal world of algorithmic procedures. This brings us back to soft computing, which as we have seen is engaged in an attempt to 'open' formalism to contingency. Yet, in my view, it is not by introducing the empirical that we are afforded a more 'open' formalism; rather, this openness is already granted by virtue of the fact that computation has intrinsic limits. I would contend that Turing cast uncertainty and randomness as intrinsic features of his model of computation by discovering the notion of the uncomputable, as this means that computation becomes defined by that which it is not: the formal logic of the algorithmic method is consequently always already 'open', as it tends towards its own limits.

We are thus returned to the import of the quantitative in computational aesthetics. We have seen that soft computing attempts to introduce the empirical into its calculations. Yet we have also seen that it does so without fully abandoning the rationality of the formal method. So, rather than focusing on soft computing's accommodation of contingency, I would argue that we should instead take soft computing as an illustration of the manner in which quantity is always already involved in the qualitative. This point can be made on two levels: firstly in terms of computer science, and secondly by way of reference to the philosophical ideas sketched at the outset of the paper. We should note that computing systems function through discrete processes: through axiomatic structures that operate via finite, and thus quantitatively distinct steps. Quantity also grounds the logical forms of computational structures, as it defines and shapes their possible configurations. Yet in Whitehead's ontology, as described above, reality itself is a succession of actual facts. Each is informed by a prehensive relation with other facts, and each has an equally prehensive relation to the quantities of their potential patterns. Earlier I described such patterns as the forms that enter into these actual facts. If we now consider these patterns of potentiality as the logical and mathematical forms of computational structures, then we would have a means of according computational aesthetics a far broader reach than has commonly been ascribed to it.

In conclusion, I believe that one of the most interesting issues that can arise from this way of thinking about soft computing is an awareness of the mutuality between factuality and formality. Soft computational structures are factual, as they are computational events with an actuality. In other words, they are acts of experience, as they inherit their constitution through the prehension of other acts of experience. This is their factual existence which, by virtue of this relationality, is possessed of an aesthetic dimension that is not uniquely reliant upon the contention – common amongst the approaches to aesthetics described above – that computational processes exhibit effects, agency and quality. I would also stress here that soft computing structures have a formality, and that this is expressed through their logico-mathematical character. For example, the procedure by which generative algorithms operate varies with contingent change: the factuality of this computational structure thus has a relation with the empirical world. In its factuality, however, it needs also to refer to what we referred to as 'forms' above, i.e. its logico-mathematic pattern, and this relation to ideality can once again be termed prehension. It is here, beyond the phenomenological outputs of computational structures, that we find the real ontological motive force of their interrelation. The forms of computation can thus be seen as an ontological, existent reality, and not just as a type of deductive reasoning that contrasts with the direct experience advocated by inductive approaches. Aesthetics, in this sense, is not the subjective judgement of the perceptual experiences that a computational structure presents to us; instead, it is the relation between factuality and formality. Although soft computing is limited in the degree to which it can help us develop this position, I believe it can help us shift contemporary discourse towards the issues that are indicated here.

AMBIGUITY AS A SIGNATURE OF THE SUBLIME IN MEDIA ART

Ksenia Fedorova

The paper focuses on the effects of media artistic representations of ambiguity in perspective of the classical aesthetic question of presenting the unrepresentable. The concept of the sublime reveals how representations of indeterminacy in relation to decentralized systems are capable of creating a temporary gap in cognition, thus enhancing the feeling of *potentia* and opening towards the reality of nonconceptual mind and interconnected being.

The concept of the sublime has been widely appropriated within technological arts and culture: as the computational sublime in relation to autopoiesis in generative art (McCormack, Dorin); and in relation to immersive virtual environments, as the digital sublime (Mosco) and anti-sublime (Manovich) in relation to data art and data networks. At the same time, the principle of ambiguity is often placed at the heart of algorithmic art, hyperfiction, game environments, interactive cinema and other genres that engage narrativity. In this case, we do not claim to make any comprehensive and systematic account of how ambiguity states itself in various media arts. This is more a methodological introduction to one of the possibilities to expand and deepen understanding of media arts through the lens of aesthetics, in particular through the concept of the sublime taken as ambiguity.

The sublime is a term of both control and surrender, of a negative pleasure, associated with the impossibility of either mental or physical representation. This uncanny feeling of being confronted with the limits of comprehension, of facing the unpredictable and the unknown, often works as a sort of litmus, testing the “seriousness” of the produced effect, the transformative potential that reveals itself through nonattachment and groundlessness. As applied to contemporary life and culture, this category becomes a “sliding” or even “empty” signifier for the space of liminality; for limits as the basis for an ontology of interaction and communication at large. Privileging heterogeneity and difference (the transcendental “Other”), the framework of the sublime refers to the questions of individuation and authenticity of the self, which is especially relevant in today’s multicentric social environment.

This quality of being in uncertainty, accurately described by Keats’s famous term “negative capability” (productive doubt, precedence of intuition and imagination over consecutive reasoning) is fundamental for artistic production. It is also extended towards media theory’s concept of “interface”, or, “intraface” (Al. Galloway) that may be interpreted as a “‘zone of indecision’, between the inside and the outside” [1] (Gérard Genette) – a zone of nonchoice between the edge and the center, inside and outside.

In the fundament of any system of relationships — and at the base of any individuation— lies a heterogeneous manifold of potential differences, a pre-individual field of singularities (French philosopher Gilbert Simondon). The tensions of singularities frame a *marge d’indetermination* (“margin of indeterminacy”), described by Simondon as a characteristic in machine / human creator relationship), a concept that opens towards the broader paradoxes of structural and ontological causality (quantum indeterminacy).

Theories of distributed intelligence, emergence, and complexity present challenges for newer types of representation of reality as a self-organizing flux, with a role of the observer as a measurer of the operations of chance. Conscious appeal to “arbitrariness” in art started as early as work by Duchamp (Erratum

Musical), Morellet, Cage, De Vries, which technically was already a prototype of “algorithmic art.” It was not always an act of a visitor (observer/user) that determined further unfolding of a work, but of an artist. The important stage was to recognize that emergence happens through differentiation of pieces of reality: that their patterns are relative and the processes of their organization into structures indeterminate. The natural continuation of this aperçu became interactive art, where a viewer is an actor determining the development of the work. Relationality and, thus, unpredictability is an integral part of both relational aesthetics and art, and interactive media art. The latter is not surprisingly compared with the quantum wave function that produces an evolving “space of possibilities” (whereas object-based art is akin to classical particles). [2] One of the classic early examples of interactive media art illustrating the principle of ambiguity is P. Weibel’s “Observation of the Observation: Uncertainty” (1973), an installation that investigates the special mood of disorientation when self-perception is given only from a third-person perspective. Is it a perspective of the “transindividual”? Does it feel overpowering and totalizing enough to name this sensation “sublime”?

Effects like change of perspectives and disorientation of the senses that are often used in media installations (Olafur Eliasson’s experiments with optics and space, Carsten Höller’s “Text Site” CAVE environments by Jeffrey Shaw, Agnes Hegedüs) produce the image of specific kinds of distance between the self and the world, a gap through which enters the terrifying, stunning, revealing unknown. These illusionary worlds allude to a numinous realm which seems to have its own self-generated ontological substance. The projects like “Sensory Environment” (2003-2004) by Chris Salter, consisting just of barely perceivable threshold levels of light and sound, confront the visitor with a direct experience of intense concentration and restlessness that arises in the process of breathing during meditation. Inability to estimate the proportions of your own body in this kind of installations often creates effect of what might be termed overpoweredness.

A range of provoking questions is engendered by conceptual dualism of complementarity and metastability in works that collide the virtual into physical reality. One of the examples could be a work-in-progress by a Russian group “Where the dogs run” entitled “Quantum Mouse” that visualizes the double-slit experiment in a form of interaction between the movements of a live organism and its virtual doubles. A mouse is moving through a labyrinth, followed by camera. Every time it makes a turn, its virtual doubles make the opposite decision.

Other examples address the reactions of anxiety and perplexity in relation to the qualities of equivocality and vagueness, as in such natural and social phenomena as (respectively) the immune system, colonial organisms, cellular metabolism, spontaneous order in economic systems, social networks, etc.

The concept of the sublime reveals how representations of indeterminacy and ambiguity in relation to decentralized systems are capable of creating a temporary gap in cognition, a disruption of conventional contexting cues, thus enhancing the feeling of potentia and opening towards the reality of nonconceptual mind and interconnected being.

CRAFTING COMPLAINTS AS CIVIC DUTY

Jamie Ferguson & Daniel Wessolek

This paper presents issues and ideas connected to the concept of complaining in general and the work of the Complaint Department specifically. Here we present two case study examples that illustrate the work and process involved, and explain why we think complaining can lead to a better world.

complaint department

One variation of the Complaint Department logo, based on a set of tools from the Open Clip Art Library and the font Vollkorn by Friedrich Althausen. Copyright by the authors.

Complaining as a means of expression should encourage the individual to acknowledge the seemingly inconsequential annoyances of everyday life as opportunities for discussion and participation. By encouraging the potential for engagement, awareness and conscious expression can be experienced as creativity and even denote performativity. It is our understanding that expression in this sense can also lead to self-worth, gratification, and even collective well-being. Studies show that emotions are as contagious as a virus. [1]

Inherent to being human, to complain was once seen as a powerful source for citizen definition and direction; to speak-up, to object and to protest was understood also as a reaction for something. The

Complaint Department recognizes the importance of a platform for complaining and sees this as a powerful means of expression and of citizen agency.

It's not polite to bitch, grumble or whine. To protest against something, which is how the term is now usually implied, is discouraged. The 'complainer' is typically depicted as self-interested, cantankerous, over-emotional, even anti-social. One might find little understanding in a pervasive market where the 'person as consumer' becomes an aggregated commodity item with little individuality. One's efforts seem lost in as many products and services and consumers out there as there are complaints to be made. Complaints are met often not without some sympathy but without agency. The current state of making a formal complaint seems curtailed to an industry operation, an endpoint having little palpable impact. Few bother, understandably, to invest the time or energy.

It is a highly valuable resource when an individual makes the decision to invest the effort and time involved in voicing an opinion. To formulate and describe an issue, to communicate this, to even go so far as to suggest a possible solution, is as close as one can get to genuine field research and user feedback. This information is a source for design strategy and conceptualizing futures. To mobilize the collective imagination, a complainer not as an anti-social but as participant for public good and improvement gives rise. Such direct and participatory methods for evaluating our present culture can lead to a better understanding of the underlying societal structures and patterns at work. A recognition of the current state of affairs can embed an appreciation for alternatives.

Complaining is at once a strategy and mode of intervention, a means to counter-act. By encouraging the expression of one's reactions to events or situations, the act of complaining can be reappropriated. The Complaint Department regards the ability of crafting complaints as a civic imperative for the public good, to which any small contribution is valuable. Enacting a call for change, choice, or accountability, citizen democracy can promote accessibility and transparency. By leveraging the freedom to disagree, those who are dishonest or do not act in favour of the public good can be discredited.

We see the Complaint Department as an ongoing art /design agency project with the goal of finding and communicating what we call improvables: design problems in everyday life that cause negative interruptions. The case study examples illustrated below present some of the issues the Complaint Department deals with. Instead of circulating negative emotions, we believe that 'room for improvement' is opened up through this approach.

Those familiar with BIXI [2] will recognize the public bicycle sharing system in Montreal that is growing in popularity. It is comparable to the Stockholm City Bikes or to Vélib' in Paris. The system is made up of bikes, bike docks, and pay stations powered by solar panels. It is an opportunity to evaluate different instances of public systems in various cities, and to think about their urban context and cultural variances. These systems have an impact on urban fabric to varying degrees and on different levels of discussion, as it seems many have an opinion or story to tell about their experience. Complaint Department is interested in how such systems can be embedded within seemingly very rigid infrastructures and how these implementations can alter one's experiences, whether this takes the form of added value and improvement to one's daily life or instead contribute stress and irritation.

In this case an attempt to rent two bicycles with one credit card failed. Normally, the casual user can purchase up to two 24h accesses on one credit card. After accessing the second bike, it was discovered that one was damaged, though no other bikes remained in the rack to choose from. The Customers biked to the next nearest stand and attempted to replace both bikes so they could begin their journey

again with equal time remaining on the trip. After replacing one bike, a second bike was no longer permitted. It appeared the number of bicycles allowed was limited to one after the first return. Were important instructions not followed or could one speculate that this scenario has been generally overlooked in the workings of the system? One might be satisfied with a reimbursement, but this is also an opportunity to enhance communication and/or usability of the system. The overall importance for continued evaluation of products in their environment over time, after they have been released into the market and have accumulated feedback, is integral.

This Customer requests a different flavoured yoghurt in his nearby grocery store. Stores of the same chain carry a variety, so he often goes to a different location in order to get what he wants. Upon request, the manager of the supermarket says he will try to fulfil the wish. After some time, Customer asks the shop manager about the result of his enquiry. The manager is very sorry, he has tried everything possible, but a store of this size is not able to fulfil this particular request due to decisions made by upper management of the chain. Customer is sceptical and decides to contact upper management directly. The representative of the chain is not aware of any such decisions, and strangely enough, some days later there are a variety of flavours available at the store. Interestingly, other suggestions made at the time of enquiry, for example, to keep discounted food that is close to the date of expiration separate from the fish section, have been implemented. Customer imagines that this follow-through might lead to a greater awareness for the value of consumer requests with a store manager, and in doing so has also improved business.

Corporate complaint departments still typically handle complaints as a problem, not as potential symptoms of a still improvable product or service. The focus lies mainly on the relationship with the customer and not losing them as a result of their complaint, instead of utilizing the complaint as resource. From our experience, complaints are a rich source for problem detection and voluntary insight that is generated by those confronted with an improvable. Complaint Department aims to detect and communicate these improvables, sometimes by describing the occurred, sometimes by coming up with design solutions.

UNCERTAIN AESTHETICS: NETWORKS IN THE AGE OF EMERGING TECHNOLOGY

Renate Ferro & Timothy Murray

We understand Uncertain Aesthetics to be a critical component in the performative spaces between contemporary conceptions of networks. The surge of digital accumulation, the continual surprise of informational texture and the layers of expressive multiplicity are what lend networks their creative power – as networks interface both real and virtual spaces.

In approaching our thoughts about "Uncertain Aesthetics: Networks in the Age of Emerging Technology," we understand uncertain aesthetics to be a critical component in the performative spaces between contemporary conceptions of networks. The surge of digital accumulation, the continual surprise of informational texture and the layers of expressive multiplicity are what lend networks their creative power - as networks interface both real and virtual spaces in public and in private. We are attracted in our curatorial and artistic work to projects that capitalize on the expansiveness of the digital and that confront the user with the realities, thinking here of Maria Miranda's exciting project of undisciplined knowledge (2009). Undisciplined, that is, as we embrace it from within the legacy of interactivity, a practice that both solicits the user to respond to a set of predetermined choices and gives itself over to the users' momentary stages, creating works and archives whose algorithms and structures leave them incomplete.

In our work we have drawn upon our reliance on artists and theoretical principles of uncertainty as they have shaped our collaborations in research, curating, and creativity to shape this presentation. Tim, a curator of new media and critical theorist, and Renate, a conceptual artist mining the fields of the public and private within the creative folds of old and new technologies, collaborate on joint projects that are framed by emergent technologies in dialogue with the layered tapestry of culture, theory, and art. Collaboratively our interventions through the Rose Goldsen Archive of New Media Art <http://www.goldsen.library.cornell.edu/> or The Tinker Factory <http://www.tinkerfactory.net/> both at Cornell University or through our curating of the –empyre- new media listserve <http://www.empyre.cornell.library.edu>, we combine technological and archival platforms while relying on unsettling, contemporary understandings of aesthetics, psychoanalysis, memory and fantasy. (We might add that –empyre- soft-skinned space is currently discussing the topic we enlist during the month of September <http://lists.cofa.unsw.edu.au/pipermail/empyre/>). Key to our shared interests is the shuttling back and forth between the public and private spheres of the archive, as the archive takes on greater weight in networked culture and as networked culture destabilizes the certainty of the archive's relation to aesthetics. As we use the archive, it is a rhizomatic relational structure that ebbs and flows in relationship to those who engage it.

To some extent, this is not something new to digital culture. The archive, Foucault wrote as early as 1969, is the horizon of "enoncés" marked by their "thickness of accumulation" which never ceases "to modify, to change, to disturb, to upset, and sometimes to demolish" (Foucault, 1969, 164). Such multi-layered thickness, which we might envision today as a fractal conglomeration of accumulated data, is what constitutes the lively energetics of the archive's erasure of previous notions of stability and certainty. Rather than grounding the specter of erasure in conventions of archival legibility, we are drawn to the expansiveness of the digital event's confrontation of the user with the realities of undisciplined knowledge. Undisciplined, again, once we embrace it from within the legacy of ruptured teleologies or

even from within the forgetful field of what Derrida understood as the differances of the erasures of archival fever.

The archive dissipates the temporal identity from which we like to admire ourselves to conjure the ruptures of history; the archive breaks the lineage of transcendental teleologies; and there, where anthropological thought interrogates the being of man and his subjectivity, the archive explodes the “other” and the “outside.” (Foucault, 1969, 172). It is in this sense of an interrogation through art and curating that we have formulated our sense of archival practice as an explosion of the outside as the imaginary boundary that separates the public from the private.

At the same time as Foucault argues for a generalized archival discourse of difference, he gestures to the promises of institutionally specific practices that might profit from the very “surface effectivity of discourse” in the expansion and accumulation of the archival event. Foucault sees in the institutional commitment to expanding resources, open archives, and limitless storage (all in the age preceding “open source” archiving) something different from the legacy of “legibility” and “memory.” For it is precisely the surge of accumulation, the continual surprise of informational texture, and the layers of enunciational multiplicity that lend to the archive its power. While “surface” might often be associated with only the threshold of memory, if not also with mere digital glamour, we are fascinated by how connective screen cultures have empowered the everyday event of the archive. The screen lives and breathes memorial reconstruction while also interacting with linked associations provided by media and networked cultures.

Most reflective of these conceptual parameters is our curatorial collaboration with the –empyre- listserv. –empyre- was initially founded by Melinda Rackham in 2002 as “a soft-skinned space,” one that would create a new public network of artists and theorists to spawn a virtual discussion of emergent practice. Now a community of some 1500 international members, the community focuses each month on the discussion of emergent topics important to the new media community, while maintaining an online archive of its ten years of discourse. Part of our ongoing commitment to maintaining and growing –empyre-, during a period when Melinda and previous managers have moved on to other projects, is to profit from the vitality of this listserv as a literal reconfiguration of public space. Initially, –empyre- capitalized on the freshness of the web by soliciting an online community via complex discourse delivered to the members’ e-mail mailboxes and simultaneously preserved for a public web archive. Now with the arrival of social networking sites such as Facebook and YouTube, which users voluntarily visit for less robust forms of conversation, we remain committed to maintaining the more antiquated e-mail format of –empyre- as a means of disrupting the now settled norms of social networking with heady e-mail blasts and monthly topographical shifts of discussion topics. While limited in scope to textual communication, –empyre- continues to resist the corporate codification of public net space while continuing to render uncertain the frameworks of networked space and global aesthetics. We even understand the fascinating amoebic syncopation of the listserv to accentuate the flow between public and private, as conceptual gaps occur when subscriber’s threads fall silent because other subscribers do not respond, or intent and content is misunderstood, or even when there is a language barrier between subscribers writing in differing languages. At all times, however, the postings accumulate, whether in singular silence or cacophonous dialogue, to result in a soft-skinned space of expansive and effervescent chatter about the ephemerality of digital aesthetics and its uncertainty.

Within both real and virtual spaces, The Tinker Factory and the Rose Goldsen Archive of New Media Art are born from similar notions of digital accumulation. Within the real space of the open lab, The Tinker Factory allows generative networking of ideas, problem solving, and skill building through practice and

tinkering. The Tinker Factory is a lab for research design, creativity and interdisciplinary technology created by Renate converging the cross-disciplinary areas of new media and emerging technology. As a space that exists "outside" of regular university programs and curriculum, the research lab, nurtures interactive, technological, and artistic research, by inviting students as well as faculty from many of the University's multi-disciplinary colleges to not only investigate technical possibilities, to engage in artistic collaborations, as well as critical and historical implications for ongoing research projects. In this workshop atmosphere, participants have investigated both the networked extension of public space and experimented with how digital and analog components might render uncertain the parameters of public space through interventions with noise, light, and networked culture.

Similarly, The Rose Goldsen Archive of New Media Art exists as a flexible library and networked space that has grown over the years to house collections of American new media art, Chinese and Taiwanese contemporary and new media art, internet art, CD-Rom/DVD Art, and, now expansive collections of video art that rekindle new media's relation with its distant past. Following the principles of undisciplined knowledge, the Goldsen Archive has set out to be indifferent to conventions of archival legibility in order to catalyze a critical rethinking of the meaning of the archive in the age of electronic art. At stake is a reconceptualization of art away from critical dependency on the narrative of history, the psychology of identification, and even the heroics of connoisseurship. Most important, its shifting reliance on online and offline platforms embodies the networked condition as grounded in tension with deeply influential institutional constructs.

Renate's on-site and on-line artistic project, *Private Secrets/Public Lies*, exemplifies the toggle between both the real and virtual spaces of the archive. Secrets and lies are at the crux of networked relationships whether they are grounded within the privacy of family dynamics or the public realm of international government relations. Most interesting is how easily the public flows between those two social constructions in the digital age. In her compelling work of non-fiction, *A Chorus of Stone*, Susan Griffin emulates the interconnectedness of how the personal experiences of an individual can have resonances into the affairs of international states directly relating to the underlying causes and or effects of war.

The inter-relationship between matters of individual privacy, secrecy, and concealment on one hand or the open, forthright, tendency for revelation were also key contradictions in the biography and life work of Sigmund Freud. It is for that reason that Renate uses Freud's writings as grounds for inspiration. In his construction of the screen memory, he provides us with insight into how memory is re-composited in the present. By looking at the past from the present we attempt to uncover the deposits of our unconscious archive of memory while acknowledging how the presentness of memory depends on the structural role of erasure through the processes of revision, re-inscription, or re-presentation, a memory conglomeration of the accumulated uncertain data/memory.

Both a performative, collaborative installation and an on-line game, the project, *Private Secrets, Public Lies* <http://www.privatesecretspubliclies.net/> showcases the collective screened memory of the participants whereby each contributor is asked to re-constitute the lively energetics of his or hers personal trove of secrets. In this project the variable of erasure is foregrounded through the underlying code and the intrigue of viral technology.

The on-going construction over time of this project as a collaboration with willing participants in the real public spaces of an installation toggled to the virtually accessible online game enables an assemblage of data traces in an ever expanding site. In the virtual version of *Private Secrets/ Public Lies* subsequent screens of the project ask the user for inputted text data, the content of which is parsed into keywords

via code and algorithms. What is left for the participant to interact with is an archive of floating data bubbles each filled with words left from previous participants. As players manipulate residual keywords from former user's information, the newly formed keyword phrase interfaces through World Wide Web via Bing. Having had their private secrets erased by fusion, the players are able to peruse news feeds, entertainment, and advertisements. The more often the interactive simulation of Private Secrets/Public Lies is activated the more often it implicitly records and archives the misguided personal information and deconstructed content and meaning of the originally intended personal information. What remains accessible on the homepage is not the original private secret but an archived list of what was subsequently transformed by player manipulation and internet linkage.

This playful translation of private data, enabled by the speed and instantaneous nature of the viral context, meaning, and intent of the original texts are playfully reminiscent of the notion of "erasure" within instability and uncertainty of Foucault's archive. The nature of evidence and memory is transformed in relation to the technology embedded in it. The real truth can neither be accessed nor verified. But, thought otherwise, couldn't we say that the real truth, at least as existent in the world of Web 2.0, consists of the active, playful, and provocative erasure of memory itself.

In a new project, Suspicious Packages <http://www.renateferro.net/suspicious/>, Renate begins to lay the groundwork for another archive, a collection of audio narratives. As participants recount situations where personal space or belongings have been under suspicion, the territories between the private and public again become blurred. Difficult to demarcate a border or marker that divides or separates, often times suspicion takes on a contested imaginary. As the project spans both the real and virtual spaces of exhibition, the object relations of packages of all shapes and sizes will trigger digital events via sensors that will illicit channels of video feedback in real time intermixed with archival footage, animation, still images, and sound.

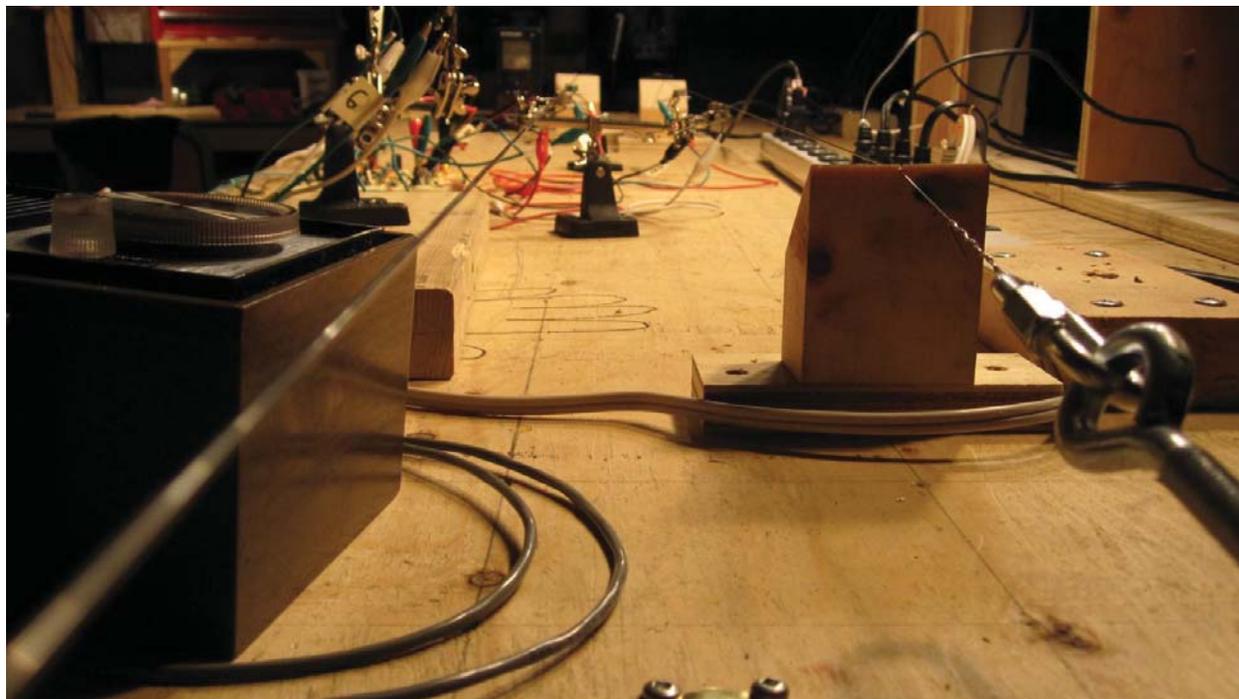

In the real spaces of emergency preparedness as Renate and Tim left New York one day after the tenth anniversary of 9/11, Mayor Bloomberg in a televised press conference urged all citizens to be wary of suspicious packages. In the very early stages of researching the project, Renate took note of the virtual links online to both the Centers for Disease and Prevention and ready.gov the place to get up to date information on emergency preparedness. The relationship of information on the virtual site and the urgency to manage the panic of an event in real space and time were sources of reflection for the relationship between an artistic archive online and the manifest of that in a real time exhibition space.

Our aim in presenting the cross-pollination of both our independent and collaborative work, work that remains between the interstices of the real and the networked, between the Goldsen Archive for New Media Art and the Tinker Factory is not only to move between the creative and research worlds in new media arts, but also to continue to forge innovative initiatives that will expand our notion of the archive itself and the range of relational artistic interventions in its midst. Additionally, these parallels lay the conceptual groundwork for future cross-disciplinary ventures where the value of conceptual tinkering with technical and physical tinkering opens the possibilities of inventive research with the network of uncertain territories.

VIBRATIONS AND WAVES

Peter Flemming

I am a folk machinery artist, doing electronics handcraft 'by ear,' tinkering intensively and intuitively in the studio. This paper discusses my current work *Vibrations and Waves*, an ongoing series of experiments about sound and resonance. Along the way, the paper introduces some working methods in my studio practice.

Vibrations and Waves, 2010-2011 (in progress, Peter Flemming, piano strings, turnbuckles, helping hands, wooden table, wooden blocks, DC power supply, electromagnetic coils, glass, mouth-harp, 555 oscillator circuits, screwdriver, radio, Creative Commons Peter Flemming Attribution Non-Commercial Share-alike.

I am a folk machinery artist, doing electronics handcraft 'by ear,' tinkering intensively and intuitively in the studio. This paper discusses my current work *Vibrations and Waves*, an ongoing series of experiments about sound and resonance. [1] Along the way, the paper introduces some working methods in my studio practice.

Vibrations, waves, and therefore sounds, occur when machines do what they are built to do: wires hum, motors whir, gears grind, and metal clangs. In this sense, sound is a natural by-product of all machine activity, even if it is not always the intended output. Where utility is the primary consideration, these vibrations tend to be ignored or actively suppressed. [2] Mechanical systems in which oscillations are desirable include musical instruments and certain types of sound-based artwork.

In *Vibrations and Waves*, notions from intentionally sound-producing machines are transposed onto ordinarily non-musical devices, and vice versa. Undesirable vibrations move from periphery to centre stage. The normal utility value of the machine becomes a secondary consideration, as it is regarded through the lens of musical practice and its elements such as pitch, harmony, and rhythm.

By revealing the basic physical ‘magic’ within our everyday machines, structures and systems, I wish to show that they are subject to material laws that are fundamentally mysterious and outside of our absolute command. This elusive ‘magic’ is a worthwhile reminder that we are not in total control in a digital-technocratic world where total control seems to be a goal.

My interest in sound and resonance was sparked by an accidental discovery made while working in the studio. [3] A project required a silent rotating mirror. The natural vibrations of the motor were physically amplified by the spinning glass, and I tried all kinds of things to muffle the sound. After a long day and a very late night I gave up without success, and let the motor spin away undamped.

I stared at the running motor for quite some time while listening to its drone. Slowly, the annoying noise transformed into a compelling, and even beautiful sound. In my over-tired state, the motor seemed to be singing to me. There was a provocative contrast between the ‘dirtiness’ of the unadorned device and the surprisingly elegant sound issuing from it. With scrap glass and a salvaged industrial printer motor as my unlikely revelators, I realized that I was experiencing the phenomenon of resonance.

Eventually this project became an installation in which a dozen rotating sheets of glass fill a room with powerful, singing tones. Entitled *Stepper Motor Choir* (2008), this was my first sound-based work and the precursor to *Vibrations and Waves*. [4]

All things have a natural resonant frequency. This intriguing idea suggests a baseline connection between just about everything, but I will keep to the physical for now. The metal body of my 1981 Econoline van would vibrate intensely when reaching certain resonant speeds. Our bodies have resonant frequencies. As does the stapler on my desk, as do skyscrapers, bridges, tectonic plates...

The current public incarnation of *Vibrations and Waves* is a series of video documents, which I see as an extension of my sketchbook. [5] Video provides a record of a temporary set-up, and helps me clarify vague ideas so that they can be communicated to others. Most of my experiments use a limited palette of basic tools and readily available materials. To create vibrating magnetic fields I use simple variable frequency oscillator circuits, rare earth magnets and cheap electromagnetic coils. These fields sonically activate things like scrap glass, metal objects, and tensioned wire. A full sheet of plywood cum worktable has served as a resonating and amplifying surface, and also as the main staging area for most of these experiments and their documentation.

The most fascinating sounds occur when the oscillator is slightly detuned from the materials' resonant points, and when multiple oscillators act simultaneously. In these cases, the slightly unbalanced system wavers at the edge of stability, like a tipsy tightrope walker attempting to find the centre of gravity. When left to run their course, these simple initial conditions give rise to complex and surprising results: shifting and shimmering harmonics, sudden crescendos and alternating rhythmic beat frequencies.

At one point, when leaning on the table to adjust something, I noticed that even a little weight would stretch the strings somewhat, altering their natural frequency. The effect is similar to, yet distinctive

from, manipulating the electronics. I replaced the manual tuning element of the oscillator circuit with a photocell, so changes in ambient light would be reflected in the driving frequency. Modulating these variables adds to the complexity of the system. It becomes a kind of instrument that can be performed. I began to think of ways to automate this.

To do so, I have been developing a diverse, modular 'material vocabulary' of techniques and devices, which I will draw upon for future site-specific works. So far, this repertoire includes: long vibrating wires, electromagnet coils, simple oscillators, saltwater, water as weight, glass vessels, glass panes, four-bar reciprocating mechanisms, motorized cranks, electric guitar pick-ups, found object resonators, swinging pendulums, cinder blocks, solar circuits...

Machine 'performers' will converse with and manipulate these various elements: an animated pump system will use water weight to tension wires, slowly modifying sonic characteristics as it is displaced into different hanging containers; oscillators could change pitch based on ambient light levels, regulated by motorized dimmer devices and automated shutters.

Each 'performer' will hypnotically repeat simple tasks, at their own lethargic pace, independently, but simultaneously. They will combine for a cumulative effect that is subtly unpredictable and in continuous slow, fluctuation. By letting machines run the show, I hope to open up a temporary space for contemplative consideration of the forces at work in the environment around us. Connecting the visible and physical attributes of mass and light to the sonic intangibility of resonance is an exploration of the fundamental properties of the stuff the world is made of.

Mistakes and accidents such as the singing motor or leaning on the work table frequently shape the course of my artwork. They typically occur when I have met some kind of technical or financial limitation, or some material quirk asserts itself contrary to my aims. After much hair pulling, occasionally I realize that the unintended behaviour is interesting in itself. I drop the original goal and pick up a new path, letting it lead me along instead of trying to bend it to suit pre-determined criteria. Knowing how to read these hidden signposts as they reveal themselves is a crucial part of my process.

I look at what I make as the electro-mechanical equivalents of short stories. Naturally, every good story needs some tension to keep it going. In my machinic 'texts,' I try to create tension by intermixing different systems. Organic ones blend with technological ones, the old with the new, and the handmade with the machine-made. And rather than words, sentences and paragraphs, I use bolts, batteries, metal, and custom electronics.

CELL TANGO: AN EVOLVING INTERACTIVE ARCHIVE OF CELLPHONE PHOTOGRAPHY

Angus Forbes & George Legrady

'Cell Tango' is an interactive multimedia artwork consisting of a series of animated visualizations. The visualizations are based on a dynamically evolving collection of cellphone photographs contributed instantly by the public. These images, and the accompanying tags that categorize and describe them, are projected large-scale in the gallery, continuously shifting as new contributions are added.

Fig 1. A participant examines the Cell Tango installation.

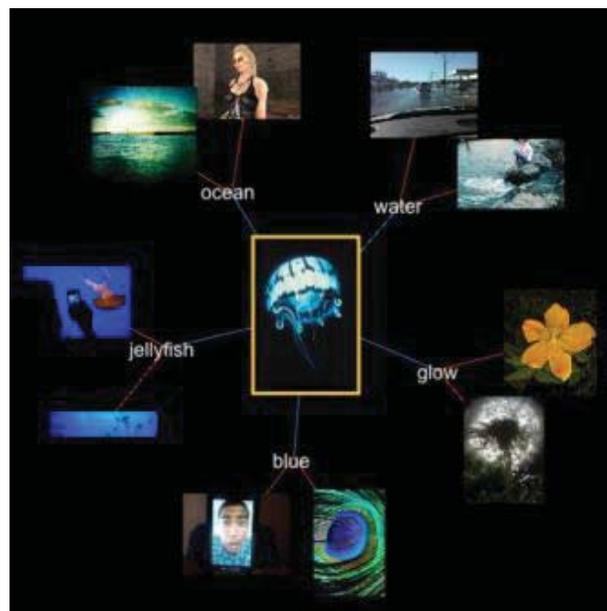

Fig 2. Detail from the 'Cell Burst' visualization. The center user-submitted photo is connected to other photos via semantic tags.

Fig 3. Detail from the 'Cell_Bin' visualization. User-submitted photos and tags are organized into a mosaic using a bin-packing algorithm.

'Cell Tango' is a dynamic artwork presented as an interactive installation in fine arts museums, in galleries, and at special events. The public visiting the exhibition is invited to interactively participate as a contributor to the project through the submission of cell phone images. These images become the primary content source of the Cell Tango artwork, and are stored online at the Flickr photo management and hosting website.

The gallery display consists of a large cinematic projection that presents the contributed cell phone images in four animation configurations – 'Cell Bin,' 'Cell Clusters,' 'Cell Burst,' and 'Cell Finale.' The public is asked to add descriptive tags in the subject heading along with each submitted image. These descriptive tags function as search queries for retrieving other images from the larger Flickr database of public photography and also as organizational devices to create thematic clusters of images. The intent is to explore the potential of unexpected juxtapositions where common semantic labels can generate interesting visual relationships.

The animation 'Cell Bin' consists of visualizing the most recent images in the database on the screen using an algorithm that selectively places large images first and then gradually fills in blank spaces with gradually smaller images until all of the empty screen spaces are filled. 'Cell Clusters' consists of thematic clusters of found images based on contributors' tags placed around each incoming contributed image that are marked with a yellow frame. The 'Cell Burst' animation throws images on the screen that then open like bursting fireworks, placing the tags once the image appears, followed by the found Flickr images associated with each tag. 'Cell Finale' concludes the visualization sequence by rapidly placing on screen all of the contributed images in the database one after the other in the spectacle action of fireworks exploding in the sky.

The artwork is dynamic – meaning that what is featured is continuously being generated in real-time according to the rule-sets of the computer code. There is a conscious approach to software development, and thus it is a form of authorship. The artwork has been designed in such a way so that the software implementation that drives the project expresses the concepts, aesthetics, poetics, and artistic intentions and philosophies of the artists. The software development involves significant engineering and problem solving, but it is driven by cultural concepts and aesthetics. In other words, it was designed with a creative pull as opposed to technological push.

Works of art tend to coalesce concerns, goals, and meaning, all of which evolve at multiple stages in the work's evolution. These stages include the initial planning and design phase and the continued iterations of transforming the design during production. Many times implicit meanings are recognized only once the work is complete, either by the artists or experts in the field whose job it is to identify what the artwork may mean. Cell Tango addresses a variety of concerns. It is an artwork that is about the creation of an archive, or collection of images – in this case limited to cell phone images. The project is based on the participatory, public contribution of data. Each exhibition represents a collection that is the sum of all contributions made by the public during the length of the exhibition. So at the start, the collection is empty; and at the end, the collection is closed. Each time the project is exhibited, the sum of all images collected during the exhibition's lifetime becomes the embodied visual archive specific to that event.

The research literature that relates to Cell Tango's foci of interests includes Kindberg's discussion on the ubiquitous transformative role of cell phone camera usage. [1] Lehtimaki discusses the increased use of picture taking from specialized occasions to the documentation of ordinary life. [2] Miller addresses the social network aspect of image storage sites such as Flickr. [3] Van House articulates a prioritization for image sharing as story telling, self-representation, self-expression, and documenting of everyday life over the long-term archival, collection opportunities that the photo management site offers. [4] The artist Golan Levin [5] has assembled a useful reference page of cell phone art projects, however most projects use the cell phone as a sound instrument in group performance, or else as control devices by which to activate events in site-specific locations, for example by turning on architectural façades with embedded LEDs. [6] The artist Jonah Bruckner created an early cell phone image-based work titled "Phonetic Faces" that consists of a mixed collage of images and portraits on a display contributed by the public present at the exhibition. This work used the cell phone to activate and control an onsite video camera that did the visual recording to a computer that assembled the images. [7]

The Cell Tango project may be understood as an exploration of the process of constructing and conveying meaning through the organization of visual elements (the images) according to a set of rules or conventions defined in the algorithms (the syntax) used to create the visualization. This positions the project within the context of a structuralist, cinematic tradition, as defined by the French film theorist Christian Metz in his analysis of semiotics and film. [8] Cell Tango follows the structuralist film theory model

of constructing meaning through juxtaposition, adding an uncertainty component as the aleatory selection of accompanying images are delivered according to common tag labels. The outcome of the selection covers a continuum from a pure literal, analogous matching visual content to visual content that may be totally unrelated at the literal, similarity level, but which may have implicit metaphoric or associative relevance. For instance, a tag that says “circular” might result in an analogous image of a tire, whereas another image which is tagged less literally with words like “yummy” or “sweet” might result in images of cell phones, cupcakes, chocolate drippings, images of a mug, a doodle, et cetera. One of Structuralism’s fundamental principles is that underlying structures lie beneath the surface or the appearance of things. [9] In Cell Tango, the algorithmic processes express the projects’ structure through its programmatic rules, and this functions as the binding by which the juxtaposed images in Cell Tango are organized. When the meanings between juxtaposed images are evident, viewers’ experience in fact becomes less interesting than when the meanings are harder to interpret. Humans naturally attempt to create and interpret meanings out of any information coming their way, and the less evident pairings turn out to be the most stimulating in the viewing experience.

The structuralist approach to art-making and information classification had significant influence in the 1960’s. This approach was initiated through anthropology (Levi-Strauss), and migrated to cinema (Metz), literature (Barthes), architecture, and art (conceptualism, Lewitt, Darboven, Baldessari), et cetera. Over time, the structuralist approach was challenged and rejected for its absolutist approach to the world, but it becomes of interest again considering that computational processes do function at the structural level to generate narrative forms through the articulation of rules.

Cell Tango features the interplay between two image sets: a) the ‘known’ system of the visiting public’s cell phone contributions, and b) the ‘unknown’ open system of tag retrieved associative images from the larger Flickr archive. At the start of the exhibition, the collection is limited to a few starter images, but then builds up throughout the length of the exhibition, and by the end of the exhibition, the collection culminates into the unique record representative of that installation’s specific set of conditions, visitors, cultural and temporal contexts.

Our interests in opening an account at Flickr were primarily utilitarian driven. Flickr is able to process incoming cell phone messages from all the various international standards. Flickr also includes a filtering mechanism by which sensitive content is managed to a degree. Additionally, we use the site for additional editing and for storing each exhibition as a set.

Cell Tango evolved out of an earlier museum-based data collection installation project titled ‘Pockets Full of Memories’ (PFOM) commissioned by the Centre Georges Pompidou National Museum of Modern Art in Paris in 2001 which then traveled to seven other cities (Rotterdam, 2003, Linz, 2003, Budapest, 2003, Helsinki, 2004, Manchester, 2005, Frankfurt, 2006, Taipei, 2007) each having its own variation based on cultural content defined through location and audience. [10] It consists of a data collection stage where the public first submits personal objects using a scanner and then describes and categorizes the object by answers a series of questions using a data entry kiosk station. These scanned items and their associated data are arranged using a self-organizing mapping algorithm. The algorithm spatially clusters the collection of contributions whereby each object is surrounded by other objects that have the greatest semantic compatibilities. It becomes a form of emergent organization where local relationships create a global order with each object is spatially positioned to every other object in the set according to their individual semantic value. Cell Tango grew out of the artistic, cultural, and computational concerns of PFOM, but aims to alleviate the burden of site-specific data entry. There is no need to

be physically present in front of a data entry kiosk station at an art installation. Using the cell phone, anyone, from anywhere, can submit a contribution and interact with the project.

The artistic requirements of Cell Tango necessitated the creation of a robust software implementation that allowed effective user interaction via the cell phone, animation of the visual elements within the different scenes, and the extensibility and adaptability to add new scenes and to easily relocate the project in different environments. Cell Tango visualizes an evolving database of cell phone photography and it is itself an evolving project that changes according to the venue, but also in order to explore new ideas and representations.

The system is separated into four processes that run simultaneously: the data gatherer, the visualization modules, the local network management component, and the graphics renderer. Communication between these processes occurs through writing and reading from concurrent data structures, which efficiently and safely allow multiple threads to access and update the same information asynchronously.

Because the main user interaction with the system is done through submitting cell phone photography, a primary technical goal of the system is to retrieve new photos as soon as they are available. Another goal of the project is to explore the relationship between the user-submitted photos and the related public photos. In order to facilitate the rapid retrieval of new photos and the exploration of related photos, a data-gathering component is placed in a background thread that continually checks the Flickr database. The process gathers both user-submitted photos and tags, as well as related photos from the public Flickr photo pool that are related to the user-submitted photos via their folksonomic tags. A local data store is kept in memory that holds the most recent user-submitted photos and well as selection of photos selected from the pool of other, less recent, user photos.

The system uses a custom 3D graphics framework called 'Behaviorism' [11] which loads each of the photos on to hardware-accelerated textures and also provides a robust scene graph and a sophisticated set of animation and timing techniques that control the layout and narrative of the different visualization modules. Each of the visualization modules processes the data that has been placed within the local data store by the data gatherer. Visual elements based on this data are placed on the scene graph, and then rendered via a dedicated rendering thread at sixty frames per second. Animations of the movement, size, color and structure of visual elements, as well as the movement of the camera view, can be programmatically defined by adding behaviors to the timing graph. These behaviors update the objects in the scene graph at the start of each loop of the rendering thread. In addition to using hardware-accelerated textures for rendering the photos and text, each visualization module is able to use OpenGL for advanced graphics techniques, including binding to custom GLSL shader programs. Because we have had to evolve and adapt the Cell Tango project to new environments (and expect to do so further in the future), the software system is designed to make it easy to add new visualization modules that transform and visualize the photographs and tags in novel ways. Additionally, we have experimented with the sonification of the visualizations, and have developed a networking component for propagating visual or data events to another computer that transforms these events into algorithmically generated composition.

Following the 2006 premier at the International Society of Electronic Arts in San Jose (under a different title, 'Global Collaborative Visual Mapping Archive'), Cell Tango has been featured in a variety of venues that include: an opening event at a national theater in France; a month in a commercial gallery; a long media arts exhibition at a West Coast research university gallery; a 2 month exhibition at a public Mid-

western university; and a 4 month exhibition at an East Coast private university. While Cell Tango functions primarily as an artwork, it also is a research project in the study of how the functionality of photographic image-making is changing through cell phones. Each exhibition is a data collection environment as the public submits images, which are then stored for later analysis. Each venue has its own socio-economic/cultural context with some noticeable differences. User responses revealed that images were expressive of local community interests, social perspectives, and varying degrees of implementation of the functionality of photographing, from recording special events, to recording phenomena, or idiosyncratic expressions. Additionally, there is the play between the collection of submissions through the artwork's context, which is contrasted to the public images retrieved from Flickr through the associated tags submitted by users.

Since the Cell Tango exhibitions act in one sense as a process of data collection, the next obvious step is to carry out the analysis of this collected data, which we plan to do in the future. We expect Cell Tango to continue on its exhibition life, each time new adding new datasets of user-submitted images. Cell Tango came into being at a time when we are witnessing the exponential changes in cell phone technology. A key component of this project will be the analysis of the various datasets to reveal the correlation between the cultural and technological elements as they change over time.

Online recipe project

Premise

The world in which we live is an integrated system of information in which we participate as consumers, increasingly unable to experience the immediacy of what we find standing before us. For us, reality is experienced through the media, is constructed by the media, which make events, places and people whom we have never seen or met familiar to us, and compensate their artifice by giving us a feeling of immediacy of that “dramatised” reality. At the same time the media bring about a sense of nostalgia for reality, a need for authenticity, spontaneity, physicality. There is a paradox: the media tell us that they manipulate reality, but the media also spread their accusations of their own falsifications. In other words, we live in a society where even immediacy is a construction.

The case of wikileaks is exemplary of this double movement of the unveiling and dramatisation, of a staged immediacy by the media: an international not-for-profit organisation, Wikileaks, uses a coded system to receive anonymous and secret documents, to then upload them on a website. In other words, a un-transparent process where unveiling means to cover up something else (the anonymity of information, ways of checking the authenticity of the materials...); but through this website, we can find a “mediate” user with a responsible, ethical and critical identity.

A mediate reality is a reality where modern distinctions between public space and private space have very blurred boundaries, and concepts slip between one and the other, emphasising the need for safeguarding privacy at an institutional level but also as part of the media.

In such a context, secrecy is transformed from an object of desire of our collective imagination into an obsession for those who are more exposed to the media. In this way, privacy becomes a luxury for the few or for those who have the means to protect their own data from the omnivorous indifference with which the media metabolise them.

Concept

The project that I am proposing must be understood as a strong metaphor of the analytical and philosophical premise, concentrating on the following aspects: familiarity/difficulty of direct access to media legends; artifice/desire to encapsulate authentic experiences; un-transparency of the dynamic of veiling/unveiling.

In order to emphasise the omnivorous character of information and the necessity to metabolise it in order to acquire an identity, I targeted my research on the body, on food, on the legend. To reduce the body is the first movement of the concretisation of the experience, to feed is the physical expression of vital growth, to elaborate legends is the principal operation of language and communicating in the veiling/unveiling process.

At the core we find the mouth, a bodily organ used for introducing/injecting and consuming, the organ with which we exchange material and spiritual foods, real foods spiritualised in artificial delights and foods with the spirit=ideas that are materialised in recipes, quantities, data. The mouth is the cavity of

the tongue and the base of taste, the organ of technology of the word, the first medium that is freed for communication between human individuals,

The tongue maintains the finesses of taste and the omnivorousness of communication.

As an example of familiarity and at the same time unfamiliarity of the legends of the media, I will take the category of chefs, the new demiurges of an increasingly common aesthetic in daily life, who are exemplars for their capability to manipulate food within mediate/experiential contexts.

The idea of identity will be identified through the portraits of the chefs. Every chef will accept the fact that he/she will be photographed in a portrait where they “stick out their tongue”, in other words exposing their tongue to the lens: this is to emphasise the symbolic importance of it, and also to use it as a metaphor for creativity as a ludic activity, irreverent and non-normalised (inspired by the famous portrait of Einstein), but also a reference to the medical test that doctors perform on small children to check their “inner” health. Wisdom and taste.

Every chef will give me an original recipe, written by hand on a piece of paper. Even the request for hand-written materials focuses on identity, as handwriting is a characteristic of every human being, just like finger prints, to the point that it can be part of a scientific inquest through graphology, which is capable of revealing identities and intimate characteristic of the person who is writing.

In order to give a theme to the reliability of the personal experience of what is often easily created on a mediate level, my artistic work will be presented online: the online connection will be the only way to discover and experience the recipes of various chefs who collaborate. On a website the names of the chefs will be put into alphabetical order, and by clicking on each name his/her portrait will appear, seemingly normal, but instead the image will be a steganography.^[1]

In order to de-code the image and discover the hidden text underneath, users will have to download a very simple program, which will give the possibility to read the “secret” recipe.

It will be a very simple operation because my objective is not to transform my work into an unnerving code-programming exercise, au contraire! It will be an invitation to reflect on the concept of privacy through games and cuisine.

PROMOTION

A concept on the mechanisms of communication would not make sense if it was not accompanied by an adequate use of means of communication and distribution. Therefore the disclosure and modalities will have to be studied carefully, so that it can obtain much visibility, can create interest and stimulate participation.

p.s. I want to emphasise that despite the fact that a portrait with a tongue sticking out can perhaps seem unbecoming, and may accentuate physical defects, it will be of utmost importance to me to exalt the aesthetical side of the image, because the concept of beauty is part of my research: “beauty” intended as a form of seduction that takes one back to oneself.

And anyway, as another guarantee for those who are photographed, every image will be chosen with the chef involved each time, so that they can be convinced and satisfied of their photo. I will also give the chef the possibility to decide how they want to show their tongue so that the collection of portraits is not repeated with the same gesture.

After having completed the online recipe book project, as I was gathering the recipes and the portraits of people with their tongues stuck out, and I thought that the peculiarity of steganography, which is a specific technique for hiding the existence of a coded message, could be a different way of creating a social network which could be revisited and destructured and that, in contrast with facebook, which violates privacy, will use similar dynamics to a classic social network but with the difference that the profile image can become a kind of medium whereby to exchange secret messages.

This curious and playful characteristic creates a buzz with other users who will want to become increasingly skilled at using the software programme, which is steganography, using it not only on the website which hosts the recipe book made by some young European chefs, but also participating in it, uploading their own image with a hidden recipe, even if this choice will remain optional within the social network.

Therefore this would be an attempt to offer a service through an artistic piece of work, where the users will find themselves faced with a different way of using a social network without the risk that their own privacy will be violated. Another peculiarity is that the users will be able to connect facebook to wikifood so that they may take advantage of the popularity of the top social network in the world, therefore sharing photos and posts on their wall automatically on facebook, so that it becomes a means for the promotion and sharing of wikifood which is a kind of parasitic economy concept typical of capitalism in our current society.

Then I thought, instead of adding the feature of clicking whether you like something or not, I will add the option "friend or enemy", therefore after asking for a user's friendship, by accepting the request the other user will decide whether to put their new friend in their friend list or enemy list with the added bonus of being able to de-steganographise the image if they are a friend, whereas enemies will not be able to.

It's evident that this new option is a bit contradictory because the symbolic value of steganography is to hide a ciphered message, therefore its existence is hidden whereas with cryptography, which is often used to exchange messages, it is evident that messages are being transmitted, albeit in a ciphered way.

The choice of informing one's enemy of the existence of a ciphered message behind an image was adopted to create a playful environment where the user, looking for a challenge or for a bit of fun or to quench their curiosity, will slowly learn how to use steganography, transforming the virtual environment into what could be considered to be a "gym" where one can practice and train, as well as being an interactive theatre which continues to grow and develop.

In all of this architecture of images, software and interactivity, the food and chefs remain at the foundations of the project, because in our current society they have a very special appeal and therefore in my opinion remain an excellent instrument to invite people to take part.

As far as the legal aspect goes, wikifood will ask users to sign so that they can register, it will not be the same process as facebook or other social networks which clearly collect personal data to then sell them

to other companies, but rather is dedicated to not selling data using some of the rules of the creative commons where the content and the photos will be the intellectual property of those people who produced them and published them on wikifood and if they should be used by wikifood, the user will be informed.

In the specific case that they should be used by other users who are registered with wikifood, wikifood will not be held responsible for such actions.

The last but not less important characteristic is that the recipe which will be de-steganographed will not go through the server. Aruba was chosen because of the previous violations of privacy and possession of data, but Claudio Agosti made sure that the steganography software that he created gives the possibility to the user to read the recipe without it going through the Aruba server.

I think that this detail is very innovative, almost visionary, mostly because the internet will be increasingly less secure and privacy will continue to be violated, therefore users will be able to educate themselves in a playful and artistic atmosphere, which can only be a good and useful thing.

Claudio Agosti created the steganography software, whereas Fabrizio Mascheroni is at the heart of the technological side of the project, creating the software, infrastructure and graphic design of our social network. Chiara Rusconi takes care of illustrations. The name of the online recipe book is HYPERLINK "<http://www.wikifood.es/>"http://www.wikifood.es

Steganography Software to hide one image inside another

WHAT

The software is called "rabbisteg", it's a steganography software. In order to work it identifies all of those bits of digital information which, even if they were lost, would not deteriorate the image. Once they are selected, it substitutes them with those of the image which is to be hidden within it.

This is the process of steganography, because the result is an image which, in the eyes of the observer, be they human or digital, looks completely normal.

This must not be confused with cryptography, which generates content which cannot be read by a human being or a machine that are not capable of deciphering it. In this case, on the other hand, it's not just privacy that we obtain, but we actually hide the existence of data.

HOW

Normally a steganography programme analyses the content of a file in detail, it understands its multimedia format and identifies those bits that can be sacrificed. This can be applied to video or audio as well as to images. Every format which contains the "quality" or "high definition" concept maintains its sense even if its definition is diminished. Steganography can be thought of as a controlled degradation process. The bigger the content that needs to be hidden, the higher the degradation will be.

This normally used to be done with software that needed to be downloaded, installed and used by both communicators. Now it has been implemented in javascript: every website can implement it and can consent to have its users use it. It's innovative in a way that web innovations are: in the beginning it's useful for web developers, who then make their own ideas with it and use it.

Steganography existed in ancient times, but it was never implemented in an easy way for its users. The Internet has reached new heights of user-friendliness and usefulness. The challenge of the software, released under a free licence so that it is freely available to integrate into any website, is to see whether steganography can be shared in this way.

MAKE IT VISIBLE!

Fabio Fornasari & Sveva Avveduto

We present the first results of a research project, that studies and produces objects to implement new models and perspectives of art in education and research. The part we present is a medium, a narrative technology in constant evolution. We use a narrative path as an experimentation field to test and verify connections between social space and the construction of world images building a specific language in the narrative dimension of research.

Fig 1. Screen layout of the images found in the selected period in the browser MAKE IT VISIBLE©

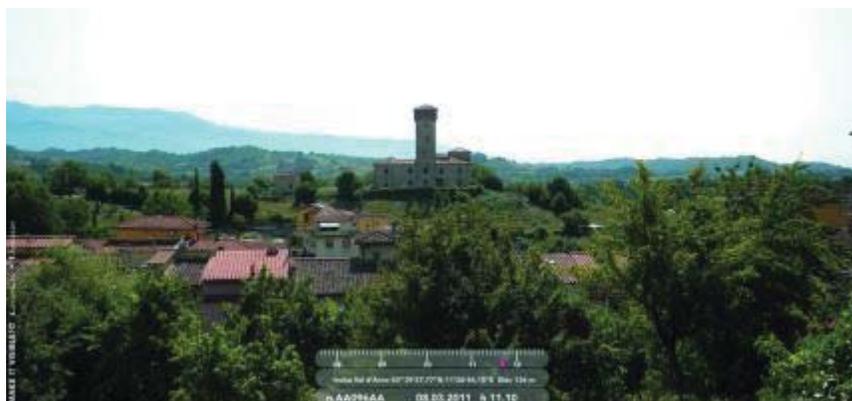

Fig 2.

Fig 3. A confirmation of what is supposedly from the reading of images. The internal roads in the country are organized on the visual center of the tower. Another highlight from the series of photos: unmarked roads are reconstructed from the vision of episodic photographers that load on the network.

There are questions that we attempt to answer since a long time. What are the real challenges of contemporary art? What are its relations with society, history, culture, science and technology?

Where will our "obsession" for interactivity and technology lead us? After the consumer society and the era of communication, does art still contribute to the emergencies of a rational society? How art resists dominant homologation? Where is the conscience? And then, how do we remember?

Science approaches results by theorems, almost aphorisms, the literature builds sinuous prose. But sometimes the opposite can be true and the language of science is almost poetry. Art communicates with us through a visual and tactile thinking. All this revolves around one goal: to enlighten the reality, make it perceptible to our senses.

The task of this work is just that: to make visible our "conscience" settled into the Net, following its tracks into "a time".

Making the invisible of science visible, occupies a good part of contemporary physics and astrophysics at first through the inductive reasoning, then through technology. Making reality more visible through technological and artistic tools is part of our work.

Explaining what we intend to do could be very simple: a search engine that operates on a stock of images uploaded to the Net, and aggregates them in "paths" that are tied to space and time. But we believe it is interesting to argue the meaning of an operation that sees the world as a building site that produces images in continuous construction.

This work stems from a simple idea: it is impossible for humans to understand their long history without being aware of how over time they came together around the forms of consciousness that are the result of continuous sedimentation.

This is what in general we call culture.

In the formation of culture, has had a significant role both the study of the reality of things, and the making a series of conceptual tools that have led to the identification of samples, examples and models that, once defined and verified, we have been able to use as samples, as a real measurement system to watch and observe everything around us according to this ideal.

The encyclopedia and the museum have been considered the two major conceptual tools, real architectures that have the task of giving structure to knowledge, make it visible and shared for a common review, to represent the models to be used to make comparisons.

The reality in all its forms can be measured and subjected to reference models.

This view of knowledge and culture is coupled with a vision of science ready to prove everything through the experimental method, towards a unique result. Since several decades we have a different awareness: science is not able to provide conclusive evidences, it is always falsifiable. Rather it is a means to understand the world and the universe around us, and then it adjusts continuously (Tattersall 2008).

If we intend to think about the history of culture, of mankind and its step on the skin of the planet, there are no experiments to conduct. Only one thing is possible: we can only observe the traces left behind, and put into a continuous relationship past and present. An interpretation that has a relational attitude: only through a system of qualitative and quantitative comparisons of the traces, you can have an interpretation of cultural history (Diamond 2006).

The styles of scientific and humanistic thought require mutual interpenetration.

There is no discontinuity in what happens around us. The idea that science and philosophy or, more generally, all the humanities are separate, falls into an old approach that divides fields of science and reasoning, that has no sense nowadays.

Technology is designed as a means to reach an end (Brian Arthur 2011) and in this sense, language is a technology which in turn uses other technologies. What we learned is that all technologies are set all together. Are not concluded in their external form, but there is continuity with other technologies included in them, combined.

For technology we mean a combination of knowledge, practices, techniques that come from applied science, communication and art.

In this sense we can say that we are writing more and more using technologies. And we also refer to technology when we talk about images: those related to the production of photographs, those related to the loading of them in the various social networks or institutional sites that host them. We refer to them also when we use a tool that allows us to navigate this body of images over time, associated with the space in which they were produced. Google Earth or Picasa, for example.

We're not talking about a hard technology, a technology that tends to overcoming the idea of "human" in a key of "body". We are rather thinking of a software, a search engine that thinks for us, and with us, the way we look at things stored in the Net. We are no longer in a time where you must fill out the Net of contents, but in a time where you have to work on the quality of landscape produced. You must make your way through this vast sea of contents uploaded on the Net.

After all, the sense of this work is to provide a tool to reconstruct the tracks within the historical context of the visions in the network path, and how this activity leaves us a legacy to continue to live the present and the future of our dwelling in the world.

Facing through pictures, routes and maps of the most interesting topics appeared on the Net. Following the joints of the medium over time, its constants and its evolutions. These are the aims of Make it visible, an atlas that seeks to make explicit the links of the vision, to look at the world with technology, geography, travel, literature, theater and other media, as well as with social relations, spaces, rituals. In other words, the consciousness of a place. This work establishes links and correspondences between images, photographs and geography, related to a time that is not just accumulation, but that can be browsed, scrolled and get across. Like a time machine for the visions.

The nature of this work would be to tracing a path.

A road in the visual consciousness of the world. The place of consciousness is the dynamic life of the whole person or the whole animal immersed in life itself.

Human experience is never alone: it takes place in the world with other individuals. The process of consciousness, as that of life, is a dynamic process that involves the world. We are at home in our surroundings. We are out of our heads.

Science, just like history. It can not be taken for granted, firm, fixed. The historical discourse is never born, it always starts again anew.

Why this focus on time, history and its way of developing?

Technology is the result of project, of design, and any technology, any design process is defined first of all in relation to time and place in which it was produced.

The pictorial turn is also well established: the images are considered by any science and discipline a proper language, turning upside down the view that considered images as somewhat misleading, as bearers of a degraded knowledge (Mitchell, 2007)

This change has now led to a simultaneous presence, visible to anyone, of the drawer full of photographs taken on the planet.

The meaning of the images is intimate and internal to the same image. But today we are interested in having the perception of a consciousness that is shown in the world and on the world.

Once the photos were just "snapshots". Today the use of geo photos made the same world a "snapshot". But living the instant removes time. And it is his limit. It leads to forget to put the space of vision in the appropriate time.

What is needed is a thought that may find in a technology a tool to make sure that all this does not become a trash for narcissistic images, but the image of same consciousness of the world. Metaphrasing-Wittgenstein: if he thinks that the human body is the best image of the human soul, then the collection of visions of Panoramio, taken as a "corpus", that is the selection and organization of the whole "corpora" that have a qualitative relationship, is the image of the consciousness of those who live in a place.

An image, produced as a thought full of meaning, emerges only if you keep the whole body immersed in its environment, dynamically.

If the avatar embodies our being in the Net taking us away from our real body, the many visions that each of us now deposited in the Net, in the "virtual" (digital) dimension of planet Earth, are more and more referring to the reality of personally experienced situations, in other words are pieces of consciousness that join with those of others within a timeless mosaic, that has lost the very idea of time. The reality in all its forms can be measured and subjected to reference models.

For centuries we have discussed the idea of presence and the idea of simulation and simulacrum.

In the act of depositing a visual memory, the idea of presence is already inherent in the vision that allows to offer the image the vision to everybody, on the one hand narcissistically, and on the other as evidence of an act of conscience and an act of living and inhabiting.

We are no longer at the dawn of that time. We are inside its adolescence. We are growing inside that time, and on growing we feel the need to organize things differently. To compute, for example.

But which images are we talking about?

We are not taking care here of images of high cultures, of painting, for example, but of the images produced on travelling, the images associated to leisure, to a glance made free from the history of photography.

In this sense, the idea of continuity, vicinity, fractures and survival, that, after Warburg, we apply to the world of images, changes its status as images are often linked to the daily visions or visions of the sublime (meaning the emphatic visions that the public shares on the Net, for example those of sunsets. The landscape reinterpreted in a postcard). People shoot pictures having in mind images taken by others, that often become survivors in their visions. Images shared and participated.

The images speak and make us speak. Always. But the images uploaded to the Net, are not a synthesis, are things not acts. Acts performed by anyone, without giving them any merit. Thanks to the Net and its resources, this is the time that seems to have given at least one answer to the problem of becoming visible. At the beginning of the third millennium, this need has been solved for any representation. If for someone the goal is then to see everything, but also to have everything, for the anonymous crowd it is just to be seen (Virilio, 2005).

All this is now possible and it is even more not only as an opportunities but also as an experience.

The word experience includes thinking, feeling, as is manifested in the perception of the world before us.

The earth, our planet, thanks to technology has become a thinking thing. Our consciences are intertwined, interconnected. But we need historicizing in order to build a sense of all this thinking, remembering, otherwise it is nothing more than background noise.

Any science can not do without using the tools needed to perform research.

These instruments are the result of sedimentation of intelligence applied to building them. In other words of technology.

In front of an image, we are always facing the time (Didi-Huberman, 2000).

Looking at pictures in the Net is like looking at the frame of an open door: it is not hiding anything.

Any image, as recent it may be, finds a re-signification through time. The image becomes the object of a special obsession that binds its meaning to a past that constantly reconfigures it. This happens for every single image placed on the Net.

The construction of meaning in memory, builds up a new meaning to the viewer. It puts at stake the consciences of the beholder and of the picture felt as consciousness, as perceptive experience that represents the world as it has been seen.

Perhaps what we are presenting in the end is the disease which claims to be his own therapy: look, see, recognize!

DYNAMIC LANDSCAPES

SARA FRANCESCHELLI

I will illustrate a performative design research program, based on a structural (albeit dynamical) interpretation of the figure of landscape in theoretical biology. We are interested in the dynamical properties of landscapes to be instantiated by the behaviour of designed devices: we are working on a pragmatics of landscapes.

“Paysage magnétique”, february 2010, in the framework of the workshop “Dynamics of a Landscape”, in collaboration with the research program Dynlan. Students: Maia d’Abboville & Ferdinand Dervieux. Copyright ENSAD.

Morphodynamic narratives

ONE. CHANNEL

On a tensed membrane presenting maxima and minima, balls of different size are falling down. Sometimes they stop in local minima of the membrane. A second tensed membrane lies under the first, and they are connected by a channel.

TWO. TECTONICS

Potentially interacting agents are irregularly distributed on a plan network, at rest. They attract each other whether their distance is equal or less than a critical value. This condition can be produced, for example, by an external perturbation. Their topological disposition may thus change, and the global form of the surface be modified, folds appear.

THREE. A NETWORK OF SINGULARITIES

Imagine a network of singularities, dispersed in the three-dimensional space. Local maxima, local minima. They are interconnected. This connection is materialized not by linear links, but by surfaces. As in a dance, each equilibrium is nothing but a frozen instant of a global morphodynamics. An equilibrium can be destabilized, following certain tendencies. A local maximum can become a local minimum, while other unstable and dynamic equilibria are deploying their connection surfaces. We assist to a – periodic – revolution of the mutual equilibria.

FOUR. FLUID SCENARII

Insistent attempt of an encounter. Pressure. Resistance. Crossing a threshold. Modification of the form. Explosion. Surge. Fall. Dispersion. Extinction. Agglutination. Da capo. (Fig. 1)

Each of these morphogenetic narratives is compatible with one of the prototypes that have been produced in the framework of workshops on performative design held in ENSAD, Paris, inspired by the figure of landscape in theoretical biology. Some details on the context of the teaching and research experience in which these workshops took place are given in. [1] The idea was to provide to applied art students an introduction to the figure of landscape in theoretical biology through the presentations of some researchers in the field. A brainstorming with the researchers and with some teachers of the ENSAD - also involved in the project - followed this introduction, in order to help students in formulating a project of prototype, to be realized in the following weeks. In which sense the figure of landscape can be connected with morphogenesis and morphodynamics? And how can it inspire an experience of performative design?

The figure of landscape in theoretical biology

In every day language the term “landscape” has several acceptations. The most obvious are perhaps the ones referring to landscape as an expanse of scenery that can be seen in a single view: a desert landscape, for example, or a picture, or an artistic representation depicting this expanse of scenery. In our research, however, we are referring to another acceptation of landscape – we will not consider a material landscape or its image, but an abstract one that, nevertheless, also concerns vision: the landscape considered here emerges from contemporary science practice, it is a mental picture offering a theoretical view on morphogenesis and morphodynamics in systems composed by interacting agents evolving in an environment.

From the theory of evolution to embryology and statistical physics, the “landscape” metaphor - qualified as “adaptive”, “epigenetic”, or “energetic”, depending on the domains under consideration – presents a characteristic shape defined by peaks, pits, and cols. An example of recent interdisciplinary research in theoretical biology dealing with landscapes is given in Armando et al. [2] These figures played and play an important role in the development of biology, from population genetics and evolutionary theory to embryology and epigenetics, since they entrance on the scientific scene during the 1930s. On one side, the adaptive landscape, introduced in 1932 by Sewall Wright, one of the founders of modern synthesis, is described by this author, as a

“diagrammatic representation of the field of gene combinations in two dimensions [...]. Dotted lines represent contours with respect adaptiveness.” (from the original caption) [3]

In this representation the dynamics of mendelian populations on this surface is expected to go towards local maxima of fitness. On the other side, the epigenetic landscape introduced by Conrad Hal Waddington is qualified by Waddington himself as a mental image, a representation by a diagram of the developmental system of an embryo:

“Although the epigenetic landscape only provides a rough and ready picture of the developing embryo, and cannot be interpreted rigorously, it has certain merits for those who, like myself, find it comforting to have some mental picture, however vague, for what they are trying to think about.” [4]

From a morphological point of view, the common shape of these landscapes (hilly surfaces) could suggest an analogy with the images of potential or energy landscapes for dissipative systems in mathematical and physical literature. However, Wright himself affirmed years later the introduction of his landscapes, that he did not meant to give them this mathematical connotation. He was indeed interested in suggesting a visual metaphor and in using its rhetorical power in order to render his own theory more understandable and to promote it in the wide community of not mathematics trained biologists. If in the case of Sewall Wright’s landscapes images served manifestly to visually illustrate his already mathematized theory, I argue that the epigenetic landscape plays, with respect the theory it should represent (on embryo development), an inverse role: it is not an illustration of a theory, but in some respects an anticipation – an anticipation of its expression in mathematical terms. As a composite metaphor, involving variables at different spatio-temporal scales, it contains a call for mathematization of developmental processes. This interpretation of the figure of the epigenetic landscape, with all the potentialities it offers, lead my choice to build a teaching and research program at ENSAD on morphogenesis in an art-science perspective (see also papers by Jonas Ranft and Jiang Bin & Sara Franceschelli in this conference).

How to say mathematics with images

In Waddington’s 1957 version of the epigenetic landscape a ball, lying on the top of an undulated surface, is ready to move along one of the paths opened in front of it. This image is completed by a “hidden” part, underlying the undulated surface: a network of pegs fixed in the ground, interconnected, often in a redundant way, by guy-ropes and strings. Tension on the links (guy-ropes and strings) is finally assured by the fact that some of them are connected to the inferior side of the surface (imagined here of non-zero thickness). The form of the undulated surface is thus seen as the emergent effect of this complex set of relationships. This suggests that a change in the tension of a link (that could be provoked by a variety of factors, for example an external perturbation, a modified tension between two or more pegs, or other...) could modify the form of the undulated surface, thus creating a new path, a new possibility for the balls to be chosen. On another side, one can also imagine that some tension modifications could be balanced by other modified tensions, so as to leave unmodified the global tension game on the undulating surface. This would imply that the paths offered by the undulations of the surface to the balls routes would not change, despite the underlying local modifications. And this could be seen as the guaranty of a certain form of robustness for the dynamics of the balls. Now, what could this image represent? Waddington states it explicitly: The undulated surface represents the fertilized egg. The path followed by the ball represents the developmental history of a particular part of the egg. As far as the underlying part, the epigenetic landscape turns out to be a composite metaphor, offering an explicit and mysterious at a time interpretation of the constitution of the surface itself:

“the complex system of interaction underlying the epigenetic landscape. The pegs in the ground of the figure represent genes; the strings leading from them the chemical tendencies which the genes produce. The modeling of the epigenetic landscape [...] is controlled by the pull of these numerous guy-ropes which are ultimately anchored to the genes.” (from the original caption) [4]

This figure points out at least two aspects of Conrad Hal Waddington vision of embryology:

- the development of the embryo is canalized along defined pathways
- the undulating surface on which pathways, or channels, are defined, is moulded by the underlying network of genes interactions.

Waddington’s non reductionist position vis-à-vis single gene action is explicitly stated:

“it is not necessary, in fact, to await a full understanding of the chemistry of single genes before trying to form some theoretical picture of how gene-systems produce integrated patterns of developmental change.” [4]

Moreover, Waddington compares the genetic actions on the whole to the geological structure moulding the valleys of the landscape: beyond the field of embryo development, structural and morphological thinking is inscribed in Waddington’s images. And this is the aspect that our research stresses.

What do landscapes do?

I argue that they call for a mathematization, setting the agenda of what a good mathematization of development should take into account. They also suggest the ingredients (non-linear dynamics, sensitivity to initial conditions, networks...) that could be at work. The mathematician René Thom, father of the catastrophes theory, inspired himself from embryology, and from these images, to create his mathematical theory. Catastrophe theory is a general theory of morphogenesis, intended as the creation or the destruction of forms, without regarding nor the substrate, nor the nature of the forces that determinate it. Waddington and Thom have been involved in a long correspondence, about a possible mathematization of the epigenetic landscape in terms of catastrophe theory. The correspondence shows some misunderstandings both on the theoretical notions associated to the landscape and on the mathematical notions that could describe them. [5] Despite these misunderstandings, and even more because of the questioning they open, I argue that the image of landscape, if interpreted in a structural, albeit dynamical sense, is a call for mathematization. It inserts itself in the history of the use of dynamical systems theory in biology, use conveyed also by cybernetics (the relevance of dynamical systems theory for cybernetics was not unknown to Waddington). Thus, if we look at the images of epigenetic landscape not as referring to objects, but to processes, possibly grasped by a dynamic systems approach, what becomes interesting is their performative power, more than their representational status. If the term landscape has, in its most general acceptation, the peculiarity of designating both the thing and the image of the thing – the signified and signifier - in our research program we are interested in the dynamical properties of landscapes to be instantiated by the behavior of designed devices. In other words, we are working on a pragmatics of landscapes. The challenge for students working with us on performative design is to conceive prototypes which instantiate some of the dynamic properties of landscapes.

What is performative in performative design?

The idea is that the morphological properties of landscapes, in their dynamic evolution, defines narratives that one could try and produce through designed devices. These narratives - thus shared by images of landscape (thought as processes) and material devices - can be supposed to be interesting on the basis of their genericity. Therefore one can work on pragmatics, with the idea in mind to eventually come back to semantics, carrying out questions and insights from the observed dynamic behaviors. If we consider the morphodynamics narratives we began with, each compatible with the behavior of a designed material device, several questions emerged from observations.

As far as the first narrative, "Channel", inspired by the dynamics of canalization on a landscape, a possible question to explore is: Can the balls pass from the superior membrane to the inferior one, and how?

For the second narrative, "Tectonics", which has been realized in the framework of the workshop "Dynamics of a landscape", the questions we tried and ask to the functioning of the device were of the kind: Which are the properties of stability and of robustness of the folded surface - globally and locally? How does the device resist to external stresses?

The third narrative "A network of singularities" is associated to a device that has been realized by a group of first year students of ENSAD in 2008, in the framework of the workshop "Paysages sensibles et dynamiques" (co-directed by the ENSAD colleague and architect Yves Mahieu and myself), which has been inspired by the notion of deployment arising from the analysis of the Waddington-Thom correspondence ([6], see also [1]). Here we took the notion of singularity as the dynamic unit around which a complex deploying surface has been designed. We worked on the calibration of the parameters of the dynamics to obtain a periodic deployment of the surface itself. In order to go further and to work on a possible interactivity of the device, questions arise, such as: How could an agent evolve on this surface deployment? Will there be any interdictions? Any ruptures? Any holes? What else - who else could take part to this dance? Interactive potentialities of this device are to be explored.

Interactivity perspective has been further explored in relation with the fourth narrative, "Fluid scenarii". This is associated to a device, "Paysage magnétique" (realized by two students, Ferdinand Dervieux and Maia d'Abboville in the framework of the workshop "Dynamics of a landscape", Fig. 1), that has been conceived following the idea that, in a generic landscape, the ball, coming from the image of the epigenetic landscape, could be a modifiable element, too. The behavior of the conceived device, in response to user stimuli, raised the following questions: Are there recurrent morphologies in function of external stresses? Can we recognize recurrent histories? And try and obtain them again? Here, thanks to the exploration of the responsive dynamics of this device, under the effect of external stresses, we found pertinent the use of the notion of "scenario", coming from the study of dynamic/complex systems transition to chaos.

In the study of dynamical systems from a mathematical point of view, as soon as non-linearity is implied, and there are more than three degrees of freedom - as it is well known since Poincaré's work on the three bodies problem - predictive power of equations is not guaranteed. In order to make some predictions on the dynamics of this kind of systems, the question of establishing a good representation of the phenomena thanks to the equations is not enough: one needs to know the history of the system, its behavior under the effect of the variation of some control parameters: what does the system perform spontaneously in time, and under the effect of its parameters variations? Are there generic scenarios,

defined by generic series of bifurcations, that one can recognize? Our experience of performative design allowed us to explore this set of questions by observing the dynamic behavior of the “Paysage magnétique”, in response to the user actions.

Discussion

Without explicitly writing any equation, these performative design experiences lead us at the heart of the questioning about dynamic and complex systems behaviors, that the figure of landscape synthetically grasps. We followed the idea of not designing objects, but processes generating families of objects. From a practical point of view this has been translated in designing parameter controlled devices. We worked on mechanical, analogical devices without using the digital as a source of morphogenetic research. We worked on a qualitative basis, but theoretically there is no opposition with digital, morphogenetic research flourishing in architectural and design research, as for example in the work of Mark Burry, Hachim Menges, Michael Hensel, Aliza Andrasek... The tension analogical/digital, that we will explore in our further research, is not but a reactualization of one of the founding debates at the core of cybernetics, and still of great pertinence.

FLO)(PS : BETWEEN HABITUAL AND EXPLORATIVE GESTURES

Karmen Franinovic

The perceived affordances of an everyday object guide its user toward habitual movements and experiences. Physical actions that are not immediately associated with established body techniques often remain neglected. Can sound activate those interactions that remain latent in the physicality of an interface? This paper presents the Flo)(ps project, an ecology of interactive cups that aim to engage strangers in non-verbal communication.

Fig 1. Girls drinking lemonade and playing with Flo)(ps. Photo by Annie Tremblay. Courtesy of OBORO.

Fig 2. The Flo)(ps glasses are active only when filled with liquid. Photo by Karmen Franinovic.

Introduction

What we know how to do strongly affects what we do, what we perceive and what we are willing to do. Given a glass and a pitcher filled with water, we will most likely pour the water into the glass, although its shape suggests many other movements, such as rolling and throwing the object. The latter actions, however, are neglected because we do not associate them with glass as a functional object. Abandoning such functionality in the name of exploration and play can foster existing and new types of social interaction.

The unusual sonic objects within public setting can attract and engage the user in an explorative discovery of its potential for action. [2, 3] But what happens when an everyday object is augmented with sonic gesture? In the musicBottles project, for example, the user can play music by removing the cork from the bottle, having the impression of freeing a song from the object. [5] Using the bottle as a sound container, the user expression is limited to acting with its cork as an on-off switch. A more explorative sonic interaction with an everyday object can be found in the Audio Shaker project where sounds can be mixed by interacting with an ordinary cocktail shaker. [4] Users can speak into the object to record sounds, close and shake it to re-mix them and then literally, pour out the sound mix. The object challenges users' preconceptions about the purpose of a cocktail shaker through an unusual feedback. While the continuity of Audio Shaker's responses allows for a more explorative interaction than the discrete feedback of the musicBottles, both interfaces engage habitual actions: opening a bottle or pouring sound. But how can an everyday object guide the user toward the space of unusual and explorative gestures?

The coupling between action, sound and object seems to play a key role. The material aspects of an interface, such as its shape, weight or texture, afford an energy transfer between the body and the interface. When interaction is designed around such physical qualities and without reference to another known object, the user has to discover how to generate sounds. Such process of learning is enabled by coupling action to sonic feedback in unusual as well as in expected ways. [6] Whereas the former fosters discovery, the individual repertoires of expected couplings are defined through shared, culturally encoded movements and shaped by specific personal skills, such as knowing how to skate or to play an instrument. My argument is that this existing bodily knowledge may serve as a starting point for unusual and novel embodied experience.

Flop)(s interactive glasses

The Flo)(ps are project explores habitual and explorative sound gestures with everyday objects, and their impact on social and personal interaction. It is a set of glasses that sonically respond to habitual actions such as cheering and drinking, but are also activate when certain unusual gestures are performed. Different glasses can establish connection among each other if synchronously moved in a similar manner. Their connectedness is manifested through sonic and light responses which signal to the users that they are affecting their behavior. The goal of such performative connectedness among glasses is to make strangers communicate with each other, through an everyday object, in an embodied, dance-like way.

ACTION-SOUND COUPLINGS

The design of action-sound couplings took place through bodystorming where sonic gestures were explored using different objects and materials. Individual use of the object and the interaction between two people such as throwing the sound toward someone were probed. This helped decide how to map selected habitual and non-habitual gestures to different sounds. The habitual gestures extracted from sensor data included filling the glass with liquid, raising the glass, stirring the liquid, drinking and toasting, while the unusual gestures comprised twirling, moving the glass very slowly and shaking the glass. Habitual gestures generated sound of liquids such as pouring, while unusual movements opened up unexpected sonic spaces such as the sound of the storm. The movement of the glass continuously changed the qualities of the sound in order to give the user the feeling of an ecologically natural experience - in

the sense of cause and effect logic found in physical phenomena. [7] For example, tilting the glass would make some virtual water come out and then stop until the user inclined the glass more in order to pour out the remaining water.

EXPERIENCE DESIGN

The glasses respond to the user only when they are full, and otherwise sit quietly waiting to be filled with the liquid. Once filled, the glasses begin to pulsate luminously and emanate the sound of water drops, each in its own rhythm: faster and irregular, slow and in patterns or slow and regular. Different responses aim to communicate specific identity of each glass - one is energetic and nervous, one is slow and relax, one is determined and clear. Their behavior is intended to attract the visitors: as they approach the glass the volume of the sound increases, and once the glass is grasped the dripping fades out. The habitual actions, which are expected to be firstly performed, activate sounds of liquid. Starting from existing action-sound repertoires, the user is guided into new movement spaces. For example, twirling the glass activates the sound of the wind. The wind sound grows louder and more complex if the user continues to twirl the glass.

When the movement is synchronous, same light and sound patterns are displayed in both glasses. The aim of using the light feedback is to establish visual link when users are too far apart from each other. The connective sound responses become stronger as the users move in the domain of non-habitual movements with the glass. In this way, the users may influence each other's movements through the sonic and light response of the glass. The goal of connected behavior of The Flo)(ps is to allow the users to collectively perform and "to dance" with each other stimulated by the sonic response to their gestures. [1]

EVALUATION

Considering that the main goal of the project is to connect strangers through performative acts with everyday objects, the evaluation aimed to reveal the social potential of the system and to gain understanding into individual experience of using the Flo)(ps within public setting. The artifacts were exhibited at the Oboro center in Montreal, Canada over three-week period at the International Design Biennale, St. Etienne, France over four-week period. In the Oboro exhibition the users could drink beverages from the Flo)(ps, whereas this was not possible at St. Etienne Biennale due to the large number of approximately 85.000 visitors. In Oboro installation, each of the three glasses was associated with an area of the bar below which the speaker was located. Chairs were used to keep the visitor's interaction bounded to that designated bar area. The drinks were served in the late afternoon and evening of each weekend, at the exhibition opening, events such as Journees de la Culture and special organized visits that lasted from two to five hours.

The range of social experiences that emerge within public context in large part cannot be predicted. [3] Thus rather than focusing on a specific task which could be quantitatively measured, we preferred to qualitatively evaluate user's interaction with the system without any previous instructions. We used questionnaires and direct observation including participant observation, design-adopted video ethnography and the informal interviews. These methods were applied sequentially in order to avoid guiding user experience through questions. Firstly, the visitors interactions were video recorded; then participatory observation combined with informal interviews took place; and finally, the questionnaires were

provided after the groups of visitors finished interacting. The data collected included more than six hours of video recordings, seventeen filled questionnaires and notes from the participatory observation and interviews with participants during the installation. [1]

SOCIAL INTERACTION

The average interaction with the glasses took fifteen minutes, although many visitors spend more time within the installation while chatting with friends and drinking from the Flo)(ps. Overall, the findings about the social dynamics emerging around the objects proved to be best defined from the analysis of the video material and the insights gained through informal interviews. A number of patterns were seen to emerge including:

- **Mirroring and Synchronizing:** Participants were observed to mirror each other's movements, especially when someone discovered a new sonic behavior, as if learning from each other.
- **Non-verbal Communication:** One visitor wrote: "you don't have to talk to connect with strangers since you are already linked by the sound you are making and also the gestures" and another visitor described sound as "an extension of body language";
- **Collaborative Performance** was observed, as groups of three participants aimed to collaboratively compose sounds. This often led them to ignore the sonic and light connections as they focused on musical improvisation;
- **Simple Play** such as creating sound of clinging glasses by toasting was repeatedly performed. Participants appeared to enjoy the simplicity and predictability of the direct feedback, but this sometimes appeared to limit further exploration of interactivity;
- **Curiosity and Discussion:** Participants proposed different interpretations of the objects and explanations for their use such as glass as a seduction tool or a waiter's help;
- **Ambient Display:** During the performance with the objects, participants would stop to talk to someone while enjoying their drinks. The glasses would fade into the background until the user's attention was drawn back to their responses and play was resumed.

These observations show that the installation forged interaction between strangers, through sonic and light gestures. The light appeared to have a stronger connection effect than the sound which often appeared to be too complex to interpret. The use of light rhythmically varying in color and luminosity had an important role in establishing contact and was necessary when the overall soundscape grew louder.

Some visitors expressed desire for simpler and clearer sound responses. The clarity of interaction may be improved by reducing the number of gestures and by using simple motions, rhythmical patterns or large movements that showed to be preferred by the participants due to their clarity. However, prudence is required as reducing the temporal evolution of sonic feedback to direct responses may lead to on-off behavior that could quickly bore the user. In fact, those participants who had interacted alone desired more complex sonic behaviors. Thus, one solution to be tested is to apply simple responses when more people are using the glasses and more complex ones when a solo interaction takes place.

INDIVIDUAL INTERACTION

The subjective aspects of the experience were best described within the questionnaires and in participants reflections collected during the informal interviews. The following behaviors emerged:

- **Expressive Solo Performance:** Most visitors experienced the object as an expressive instrument. When they interacted alone, the rhythm of the performance often slowed down as they more carefully explored the sonic behavior of the object;
- **Exploring the Unusual:** Participants found it difficult to interpret unusual sounds, but were satisfied that the sound continuously responded to their gestures. One visitor wrote: “swirling it in a slightly less habitual and functional manner, it opens up an unusual sonic space. The splashing sound seems to gain in resonance. Soon after a deep howling, evocative of a storm, becomes amplified;” [1]
- **Limited by Habits:** Few participants stated that certain assumptions about what should be done with the glass affected their experience. One participant wrote: “I was more focused on solitary interaction. I guess I assumed that all that could be done with the glasses could be done alone.”. Participants enjoyed small deviations from habitual events, such as toasting with glasses of different materials (i.e. plastic glass with the sound of crystal one);
- **More Dynamics:** Because the sounds did not evolve if only habitual gestures were performed, some visitors who played for a short time period said that the sounds should evolve or change more often;
- **Introspection and Intimacy:** Many visitors who were alone in the installation used the glass as a kind of meditation tool. They were observed to stare at the drink being illuminated by the light or to slowly twirl the glass while listening to the sound of the rain or the wind. One visitor wrote: “They remind me of candles. It would be cool if they reacted to the stress in your palms.”;
- **Strangeness:** Several comments suggested that the sounds confer the sense of strangeness. Participants associated sounds to “an imaginary chemistry lab”, “stalagmite space”, “a damp basement” and “outer space”. Others, however, linked them to personal memories such as “playing in bath as a kid” or “it makes me feel like I am underwater”.
- **Fun or Function:** The presence of liquid in the glasses showed to be highly significant in affecting and constraining the way in which users interact with the Flo)(ps glasses, and the ways in which they perceive them. If the glass was activated when no liquid was in it, it was interpreted as a musical instrument, a toy or a magical device.

When performing individually, the participants were more attentive to sensuous responses of the system. They explored more deeply the transitions between habitual and unusual gestures while forming new interpretations for sonic and luminous behaviors of the glass. The distribution of the attention of the user appeared to be central to shifting between different types of interaction. Although the user interaction cannot be predicted, the spaces in-between the solitary and collective performance and between habitual and unusual gestures need to be well choreographed.

Conclusion

I have described the design and the qualitative evaluation of the Flo)(ps project that aimed to stimulate connectedness among strangers through sonic movement. The goal was to explore the space in-between the habitual and unusual sonic gestures with an everyday object. Using a familiar object such as a cocktail glass showed to facilitate the first exposure to its interactivity, but it showed to limit the exploration of its behavior due to the assumptions about their use. Such objects proved to engage users in non-verbal communication, especially if the action-sound relationships are simple. Strategies for the transition between habitual and experimental actions still remain to be explored. The integration of the speaker in the body of the glass is necessary in order to improve usability and to conduct exploration within real-world context such as a dance club or a cafe. The next steps for The Flo)(ps project will focus on more abstract sonic feedback for habitual actions in order to break the expectations of the user and facilitate unusual gestural interaction.

Strangeness may be the key to exploring the boundary between the familiar and the unknown gestures, as witnessed by this reflection of one of the Flo)(ps users: "As I become immersed in my experimentation with the drinking glasses, their familiarity gradually becomes odd to me, in the way a word can gradually acquire a strangeness if we repeat it over and over again. This turn from familiarity to estrangement allows for a rediscovery." [1] It is my hope this project raised questions and awareness that such playful and embodied reflection can be stimulated and sustained through novel sonic experiences within our everyday contexts.

ACKNOWLEDGMENTS

Many thanks to Yon Visell for software development, Martin Peach for electronics advice, Fabienne Meyer and Thomas Tobler for fabrication support. This project was supported by the European Commission project CLOSED and the Interstices Lab, Hexagram, Montreal.

MAPPING UNCERTAINTY

EUGENIA FRATZESKOU

The issue of exactitude in mapping the physical world has been debated extensively in science and has influenced the formulation of scientific paradigms. New types of site-specific digital art are developing for creatively investigating the intersection between various types of reality and their exchanges. This paper focuses on how it is possible to trace and interact with the emerging paradoxes, through innovative modes of spatial intervention.

The issue of exactitude in mapping the physical world has been debated extensively in science and has deeply influenced the development of scientific paradigms. According to Lev Manovich, a fundamental paradigm shift characterises the transition from Modernist reduction and abstraction to complexity in art and science. [1] As we pass from Modernist mathematical formalism to complexity, uncertainty and complementarity, our perception and understanding of the relationship between physical and virtual worlds are changing in the most unexpected ways. The developments in Quantum physics and scientific visualisation have revealed an emerging kind of multiple dimensionality that characterises the fuzzy boundaries between reality and virtuality. As a result, a new understanding of space and reality in general, as well as of the limitations of science, is developing. A closer investigation of what is understood as paradigm shifts, may show certain ambiguous interchanges between reduction, abstraction, complexity and complementarity, in a context where not even a single definition of complexity seems to be universally accepted. This situation is most revealing of the inevitable limitations and shortcomings that characterise our attempt to study and map reality.

The creation of algorithms is part of the development of mathematical formalism that has been based on the probabilistic relationships between predetermined abstract sets marking the transition to the 20th century rationalism, the abstract vision of Modernism, the excessive trust and over-confidence in digital technology and visualisation. Data visualisation and scientific simulation have been largely used in science and across disciplines for visualising and investigating the co-ordinates of the real world. Despite early hopes however, new technology has not eliminated indeterminacy. The workings of Virtual Reality (VR) itself are inconsistent. Based on software engineering and media theory e.g. Friedrich Kittler's writings, although programmers struggle to remedy noise – the inherent side-effect of the chip, which may include diffusion, quantum mechanical characteristics, etc. – machine reduction and constraints, an inherent degree of randomness and the increasing incompatibility between the diverse computational levels haunt digital technology even more. [2] Simulation includes processes of analysis as well as of synthesis. The algorithmic infrastructure of digital visualisation systems is characterised by precarious interplays between abstraction and complexity. New ambiguous relationships between part and whole emerge due to such interplays. The world appears to be unconnected, diffused and uncertain, as it is visualised through the algorithmic veil of digital geometry that is not only abstract but also unstable and paradoxical. [3]

Instead of seeking to achieve the unattainable, that is, to map the changing reality with exactitude and certainty, the most relevant challenge would be to map the boundaries and uncertainties of our knowledge and its applications. The use of data visualisation, scientific simulation etc., can be contradictory. On the one hand, digital visualisation is used as a means for analysing, simulating and predicting reality, evoking thus, a sense of objectivity, certainty and control, as the probabilistic space of VR is forced to

look real; as possibility becomes a kind of reality. On the other hand, it is broadly acknowledged that emergence derives from complexity; from invisible, interacting and unsettling potentiality fields. Complicated beginnings emerge as there is no ground zero, while elliptical ends occur due to a constant asymmetry that causes new fields of creative possibilities to appear. Such a condition of emergence calls for new modes of presentation, interaction and aesthetics, in relation not only to the issue of boundary but also of understanding reality per se. Instead of ignoring or introducing unpredictability and uncertainty, their hidden existence in digital visualisation systems can be creatively revealed and explored in depth. In this way, new modes of innovative practice that do not comply with the established doctrines of representation, formalism, constructivism and their opposites, can be developed.

In contemporary art, architecture and the related disciplines, the changing relationships between data flows and data matrices inspire new types of spatial research and practice. As a designed environment, built space can be perceived as a fragment of an excessive superimposition of dynamically interacting algorithmic, geometrical, topological and structural grids. A creative exploration of the data that flows into, from and within the physical structures of the built environment, challenges our common assumptions about space and our experience of it.

Instead of perceiving it as neutral and stable, space is heterogeneous and uncontrollably evolving due to its multiple layers of virtuality and reality. As Lev Manovich states, the influence of Quantum Physics and Manuel Castell's concept of informationalism is particularly evident in the development of digital and media art, while the most interesting and challenging art is created through the interactions between the various layers of space. [4] In this way, it is possible to surpass the limitations of producing a neat and settled hyperspace that is characterised by the unity and continuity of spatial augmentation. One of the most challenging possibilities arising, is to creatively reveal various interstitial spaces of emergence that derives from complexity; from the invisible and unsettling potentiality fields between the transitional states of spatial transformation and exchange. Imperceptibles and intermediates would emerge, as we unravel what is observable. The latter can be perceived as the outcome of the various intersections of interacting fields and the ruptures that emerge from the changing and heterogeneous nature of the layers of space. An oscillation between atopias, utopias and dystopias may challenge the established borderlines between a plan, a map and a building, as well as their meaning.

The opportunity to reveal and challenge the relationships between diverse kinds of reality and perception, can be realised through exploring various types of interstitial space, by creating innovative and unsettling spatial interventions. Certain emerging types of digital site-specific art enable the creative investigation of the intersections between various types of reality and their exchanges. For instance, Pablo Valbuena uses mutually interacting digital input and output processes for enabling in-situ spatial projections, injections and incisions, so that para-sites are revealed through light-based drawing. [5]

Creating inter-passages between digital and actual spaces forms part of the author's practice. The emphasis is placed on how interstitial spaces, in terms of code and maths, can be revealed in a physical space, where perception levels can be crossed. New modes of site-specific drawing are developed for tracing and interacting with the half- and by-products of algorithmic flows that remain unbuilt, their meta-dimensionality and the emerging paradoxes, through different modes of innovative spatial intervention. Instead of creating a singularity e.g. translating a digital design into a building, or developing progressions and sequences as in animation, the aim is to create inter-passages between the unsettling heterogeneous and interacting layers of architectural space. Interstitial spaces can be creatively revealed through the use of material/immaterial mediums such as light and line as well as through the

processes of drawing and diagramming, for opening up the interfaces of thought, VR and built architecture. Innovative spatial interventions can be realised through a) site-specific drawing of and onto the actual site, b) interactive spatial diagramming as realised in a site-specific semi-immersive virtual environment. When entering interstitial spaces, viewers encounter neither a mere place, nor an absolute or utopian space, but a kind of inter-passage between real conditions, VR and thought, where an unprecedented kind of spatial experience emerges. Inter-spatiality enables a new philosophical understanding, experience and perception of space, inspiring new types of spatial research and practice in art, architecture and the related fields.

FRANKENSTEIN2; OR, THE MONSTER OF MAIN STREAM

Annabel Frearson

Frankenstein2... is a new novel and associated works created using all and only the words from Mary Shelley's *Frankenstein; or, The Modern Prometheus* (1831).

Extract from Frankenstein2... as performed by Alex Walker.

Frankenstein2; or, The Monster of Main Stream is an ongoing project which involves rewriting Mary Shelley's 1831 novel, *Frankenstein; or, The Modern Prometheus*, using all and only the words from the original to create a new, contemporary story. During the course of its production, extracts of *Frankenstein2...* have materialised in a variety of contexts and media, examples of which I will be presenting at ISEA2011.

The following is a piece, produced for a recent group exhibition in London (UK) on pornography. It was displayed as a large scale photographic print and performed as a rehearsed reading by an actor with a Scottish accent.

Bear in mind that the following words all derive from Mary Shelley's *Frankenstein...*

"This is your captain speaking." I am on a flight to Rotterdam. Business class. Oh yes. Duty Free breakfast: bring it on! By the time we take off I am feeling fully accomplished. Here I am, eye to eye with a wondrous herd of congenial snatches as the cabin crew sallies down the isle for the safety routine. I willingly consent to being restrained in the bondage of my seat by one of these bright blue angels of the air. I admire her immaculate apparel and chemical proficiency, lingering over the sound of claspings metals as one side is glided in to the other with a satisfying 'chink'. Her name is Brandy – or could it be Caroline, or perhaps Dawn? – and she is Austrian apparently, not from Holland. Either way, her accent is diabolically alluring and full of the plaited rustic charm of hay meadows and snow-clad peaks as it flows into my ears like a trickling mountain-stream. How annoying when we are interrupted by Bernard's choicest cheese and cheerfulness. Quelling my embittered discontent with hard spirits I find the Southern Comfort comfortless but it nevertheless has the unexpected advantage of rendering me so absolutely, assuredly, audibly, barbarously, completely, deeply, dismally, dreadfully, eminently,

leaves the cloudless sky to penetrate its watery grave. And then I awake, still in the airport departure hall, with a pool of stiff cold seamen slowly descending southwards.

THE VJACKET: ENABLING THE VJ AS PERFORMER WITH RHYTHMIC WEARABLE INTERFACES

Tyler Freeman & Andreas Zingerle

The VJacket is a wearable controller for live video performance. It is worn by the performer or visual artist to control video effects and transitions, trigger clips or scrub frames with the output of the integrated sensor system. The sensors detect body movements like bending, touching or hitting, and can send OpenSoundControl or MIDI messages wirelessly to the various VJ programs, bringing the rhythmic movement of dance to computer interaction.

Sensor layout for the first prototype VJacket, 2010. It includes a LED on one wrist and light sensor on the other so you can cross wrists to trigger video effects. Image copyright A. Zingerle.

Introduction to VJing

A visuals jockey, or VJ, is the visual analog to the disk jockey, or DJ. As the DJ selects, combines and mixes music, the VJ uses tools to dynamically change the visual appearance of a space, often in alliance with the music and the crowd. Performers who are more affiliated with the art world than the electronic music scene may label themselves visualists or live cinema artists rather than VJs. VJing can be seen as an advancing wheel that provides a good platform for experimentation in material, forms, content or presentation formats and displays. [1] Although several festivals dedicate themselves to the VJing culture, clubs and nightlife remain its primary platform; in the club setting, VJs use video, film projections, lights and even smell to accompany a DJ's music set and to interact with their audience. [2]

Often the VJ uses short clips from disparate sources like archival films, photography, and computer generated animations that can be looped, remixed, combined, and arranged in countless ways for unlimited visual possibilities. Like the DJ, the VJ operates live and manipulates different media formats according to the content mapping, the visual expression or temporal and spatial montage. [3]

Several different software packages are available that can handle a wide variety of visual material. Often VJs use MIDI controllers to more easily trigger their clips, presets or effect layers. These generally-used

setups bond the VJ to the computer, restricting him mostly to a seated position behind one or more screens.

Enabling the VJ as Performer

VJing is a rhythmic manipulation of moving video and animation. A mouse and keyboard are not ideal rhythmic controllers because they are very rigid and unforgiving. It's common for a VJ to experience difficulty scrubbing a video rhythmically with a mouse because the mouse is too precise in position and too slow in response for gestures of rhythm, which are innately imprecise in position but very precise in tempo and response. Knobs, sliders and touchpads are more responsive than a mouse, but still require tiny movements for grand rhythmic gestures, and require precise position and attention (most knobs can only be turned by two fingers at once: a precise movement).

A more natural controller for such tempo-centric manipulation would mimic the movements of dancing, since dancing is the ultimate form of rhythmic expression. We see this concept in several new experimental VJ interfaces, including the maraca-like interface 'Rhythmism,' [4] and the 'WiiJ Video' interface, which uses the Nintendo Wii remote to control video through sweeping, rhythmic hand gestures.

We sought to extend the gestural concept, past just the hands to all parts of the body, to enable a VJ to control video simply by dancing. We embedded sensors into clothing to ensure minimal encumbrance from the interface. The VJacket allows for wide, imprecise movements with a precise rhythmic response. The VJ will not have to fumble for knobs and buttons or have to look at the screen to be sure he's clicking on the right thing – he will be freed to control the video using his body movements alone.

Because the VJacket is wireless, the VJ is free to interact with the audience and musicians on stage or even walking through the crowd – something which most hermit-like VJs do not usually experience, since they are often relegated to the back corner of the club behind the video inputs and lighting controls. With a wireless system, a VJ becomes not just an engineer behind the curtain, but an actual live performer – one whose movements are directly connected to the video projections. The audience will be able to see the VJ's gestures in connection with the video, and thus will become more interested in the performance itself.

Reeves et al. explain the importance of “expressive latitude” in a performance: the stylistic gestures a performer makes “that are not directly sensed by the instrument.” [5] Wearing the VJacket, the performer transforms these superfluous gestures into *direct manipulations* of the instrument – indeed reducing the expressive latitude, yet simultaneously merging that expression into the movements of the video performance. The bend of the arm, the slap on the stomach, and the wave of the hand are no longer purely showmanship but are given meaning in the visual context provided by the on-screen projections, synthesizing the performance of the body with the performance of the technology. “Such gestures are an essential element of deliberately performing interactions for others to see and appreciate, expressing skill and control and introducing an aesthetic component to the use of technology.” [2]

It is our ultimate goal to connect the VJ with the audience since doing so will create a more legitimate space for VJing within the performance community, and we hope to encourage more people to try VJing themselves. With video and consumer production becoming more ubiquitous, projectors becoming

cheaper and smaller – even integrated into our cell phones and cameras – soon every rock band, DJ and karaoke bar will have its own VJ. If they don't, someone with a pocket projector and mobile VJ setup will guerrilla VJ anyway. This is the future we envision, and we are trying to shape it with the VJacket.

Free the people

In recent years, several research projects have focused on the controllability of live performance, such as the multitouch surfaces 'reactTable' by Sergi Joda [6] and the 'Vplay' by Stuart Taylor [7]. However, other projects spotlight the performative quality of the devices by freeing the artist from his 'behind the screen' position and allowing unfettered physical movement on a stage or within the audience. Representative examples make use of neural interfaces like the 'Nervixx' by Tokuhisa, [8] or camera-based motion tracking like the 'Kinect + Visual Synth' project by VJ Fader.

We combined ideas from both percussion-based devices, such as the maraca-based 'Rhythmism,' [4] which transforms a simple percussion instrument into a VJ performance system, and more precise expressive instruments, such as the 'Djammer,' a handheld device that can be used for 'air-scratching' – giving the DJ the possibility to leave his turntables and move around in the nightclub [2] – to give the VJ a wide range of control possibilities: traditional scratching and fading combined with percussive elements for triggering effects or clips.

The Dutch performance artist Eboman created the 'SenSorSuit,' a suit that he uses for staged body performances, mixing live video and a network of sensors spread over his body. The SenSorSuit is full of bulky sensors and other equipment which must be taped onto the body. In contrast, we tried to make the VJacket as unobtrusive as possible, enabling the performer to just slip it on and switch it on with very little preparation time, making spontaneous performance more feasible and more comfortable. Unlike the SenSorSuit, which is a complete performance instrument, the VJacket is meant to be used in conjunction with other interfaces: it can provide basic functions that the VJ uses most often (e.g. global effects, clip loading, mixing and scratching) and keep them easily accessible, leaving the more complicated, lesser-used functions to other controllers, such as a piano keyboard, sequencer, or even the bane of live performance: the mouse/keyboard on the laptop.

Hardware Considerations

The VJacket uses a Bluetooth Arduino microcontroller board to wirelessly relay sensor data to the computer. The same way the printing press enabled the masses to experience art, the Arduino and other DIY open-source movements have enabled the masses to make their own cybernetic art and personalized technology – creating “products for a market of one person... You don't need personal fabrication in the home to buy what you can buy because you can buy it. You need it for what makes you unique, just like personalization,” as Neil Gershenfeld said in his 2006 TED Talk. We wanted to see where other people could take the VJacket idea, so we made the hardware and software open source and wrote tutorials on how to make your own VJacket – from building the circuits to mounting the sensors on clothing to using the software to control any aspect – and posted them to various DIY communities, as well as gave workshops to urban youths to empower them as creative entrepreneurs in their communities. [9]

To encourage this extreme personalization, we made VJacket hardware modular, with the capability to choose exactly which kinds of sensors you use. The original version had bend sensors in the elbows to control visuals by bending your arms, a linear (ribbon) potentiometer in the lapel to offer finer finger control, and photoresistors and piezo hit sensors for more percussive movements, but the circuits and software were designed as to allow any combination of sensors.

For example, in a later iteration of a VJacket designed for step dancer Geoffrey Frimpong, we used only percussive piezo sensors, so he could slap different parts of his jacket during the dance for a dominantly rhythmic, staccato audiovisual performance. Kevin Brito's dance style is more smooth and flowing, so he preferred the bend sensors and slide sensors during his performance. With such customizations, each sensor in a person's VJacket is an extension of that person's style: just as an expensive suit is tailored to follow the contours of an individual's body, the VJacket's sensors are placed to capture and accentuate the performer's natural style, creating a highly personalized instrument.

Slayden et al. found during user-testing with experienced DJs that "the interface had to be operated in a manner where one could develop good proprioceptive sense for and development of muscle memory, much like any musical instrument." [2] With the VJacket, the body becomes the instrument, bridging the proprioceptive gap and shortening the learning curve. We found during user testing that this learning curve is shortened even more when the user feedback is clear and expressive. Kids who tried on the VJacket picked up on the interface quickly; we noticed that when the sounds were off, the players had a harder time discerning which movements triggered a visual effect. With the instant and obvious feedback of sound combined with visuals, however, they quickly mastered the VJacket.

Software Considerations

Once you have the sensor data from the hardware, you need a way to control your performance software with it. There are many projects available that convert Arduino sensor information into messages that control various software programs, including Maxuino, Funnel, NETLab Toolkit, among others. However, they are mostly libraries that require programming experience, expensive development tools (e.g. Max 5 for Maxuino and Adobe Flash for NETLab Toolkit), and a good deal of development and testing time to use in a project. Consequently, many beginning users have a steep learning curve to overcome before they can start creating.

In order to make Arduino projects easier and faster to realize, we designed the Arduino2OSC software to accept and process multiple types of sensor input, using live sensor readouts to adjust the behavior on-the-fly. The basics are there: scaling input and output values, adding cutoff thresholds, as well as filters to smooth errant sensor data and envelope triggers to automate gestures. Once you have configured all the sensor inputs to produce the desired data, you can route the output as Open Sound Control or MIDI messages, two standards which are supported almost universally by VJ and audio software, such as "Arkaos Grand VJ, Max/MSP/Jitter, Reaktor, Abelton Live, Propellerheads Reason, Supercollider, Kyma, Processing, OpenFrameworks, etc. Using OSC, you can even send the messages over the LAN for networked performances." [9]

Another important aspect of the software is to be able to adjust the sensor values on the fly, while preparing for or even during a performance. Sensor data can change slightly from performance to performance (variables include the strength of the battery, bend sensors slowly becoming permanently bent, ambient light in a venue that affects light sensors), or the behavior could change (the act could

suddenly call for a “bleep” sound when there was a “bloop,” a cut when there was a fade, etc.), so the performer needs a way to adjust for unforeseen changes without opening up the development environment and changing code. We built the interface to be completely customizable while it’s running, and to have customizable presets that you can load for different performance sections.

Outlook

The VJacket was designed to be a completely mobile, wearable instrument that empowers performers and expands the performing space beyond traditional music venues, galleries and museums, thus merging the context for VJing from a performance space into an audience space. No longer is the VJ relegated to the back of the room or on stage; he can also be a participatory audience member projecting his own performance as a highly individualized interpretation of the music – an extension of dance enabled by fashion. For this reason, we are developing a new version of the Arduino2OSC software, called Sensorizer, which will be available on mobile platforms (Android) as well as standard desktop platforms. Sensorizer will connect the VJacket with a mobile phone or tablet wirelessly, and use the same OSC/MIDI bridge to turn the phone into a completely mobile performance instrument: either projecting visuals via a pocket projector, or creating sounds and sequencing music. Since Sensorizer is based on the well-defined OSC protocol, other mobile developers can write audiovisual performance apps to create new uses for the VJacket and contribute to a growing resource for “guerrilla VJs.”

Developers are already beginning to write games and performance software using OSC to control all aspects of the functionality. Games like ‘Miserable Pile of Secrets’ and ‘Savestate’ [10] make possible a new avenue of interface exploration by connecting unrelated systems, or codebending: “video games can play other video games, and become generative art. Oscillators can drive web browsers. Poetry can write music.” [10] Indeed, the VJacket can also be used as an input to these systems, enabling the wearer to write generative poetry by hitting the jacket to change the word choices, or play Tetris by bending his arms. We wait excitedly to see what other people will choose to control with their own VJackets, and hope that one day, personalized fashion technology and mobile performance computing will permeate our society in a community-driven collaboration on stage, in the streets, and at home.

PARCIVAL GOES DIGITAL: NEW MEDIA AS PART OF A GESAMTKUNSTWERK

Gesa Friederichs-Buttner & Johanna Dangel

We describe the results of an evaluation concerning the spectator's reception of and experience with digital media within the interdisciplinary performance *Parcival XX–XI* of the dance Company urbanReflects and the University of Bremen. According to the qualitative interviews conducted, the audience experienced participation as 'disruption'. Four reasons can be registered: language, rhythm, limited exploration and shift of the spectator role.

Parcival XX–XI. © urbanReflects

Once upon a time...

there was an Arthurian hero called Parcival who was searching for something called the 'Holy Grail'. But what has this story of an old cup to do with us? The Company urbanReflects in cooperation with the University of Bremen associatively bases the new transdisciplinary dance performance *Parcival XX–XI* (2011) on the medieval legend of the search for a better world by showing quests for the redeeming Grail in the 20th century and by portraying their own version(s) of utopia.

Striving towards a new means of dramatic narration, *Parcival XX–XI* incorporates contemporary dance and digital media into a non-linear narrative with social implications. Not to bear up against but to converge with more traditional media such as dance, digital media shall be altered to an equal protagonist within the frame of theater. Designing digital media as an interactive experience allows not only the dancers to cooperate in the creation of *Parcival XX–XI* but also the audience. This paper describes results

of an evaluation concerning the spectator's reception of and experience with digital media. One major finding of the evaluation is that the audience experienced participation as 'disruption.' We have analysed the following four reasons for it: language, rhythm, limited exploration and shift of the spectator role.

Parcival XX-XI

WHAT IS IT ABOUT?

The narrative of Wolfram von Eschenbachs *Parcival* provides the frame for our interactive search for a better world. Analogous to the knight *Parcival*, we are on a quest for what is called utopia. Over time, humankind has discarded many ideas formerly held to promise a new world – the egalitarian ones of communism as well as the elitist ones of fascism. Interpreting capitalism as yet another 'wrong grail', the production tries to delineate current visions of utopia. It becomes a hatchery of ideas for a 21st century quest for a better world by questioning the concept of the Grail. The performance is built as a non-linear collage of atmospheric tableaux and structured into three acts: the first act 'celebrates' the breakdown of capitalism, the second act is a retrospective on totalitarian systems, and the third act envisions our very personal utopias.

WHY THE AUDIENCE SHALL PLAY ALONG?

Central to the production's interactive quest for a better future is the use of digital media. Talking about political systems and our personal visions of new human communities, audience participation is of principal interest in *Parcival XX-XI*. Parallel to our main subject, the individual in society, we thus design interactive experiences, in which the audience can witness the limits and rules of a system in a very basic way.

Digital media carries out a double role in *Parcival XX-XI*: On the one hand it is incorporated dramaturgically and aesthetically in form of interactive and / or live video sequences and on the other hand it is used as a 'tool' to allow interaction. In the latter case, Nintendo Wiimote controllers were used for various reasons. (cf. [1]) With the help of this tool, passive spectators are invited to merge into active performers to collaborate in designing the experience of the play for themselves and the other spectators. As technology-based interfaces always come with certain restrictions, also do the Nintendo Wiimote controllers. In this paper, however, the focus is not set on discussing these practical boundaries but rather on its major dramaturgical impact to *Parcival XX-XI*.

Designing Interaction

While designing *Parcival XX-XI* and its participatory moments, the two following questions were our constant tutor: First, how to design such opportunities in order to make the audience's action and its effect for *Parcival XX-XI* understandable for all 'players', and second, how to communicate the fact that the audience shall participate in the play and when. Talking about the first, a differentiation into three major tendencies of understanding can be summarized: understanding on a technical level, where one learns how to command via Nintendo Wiimote controllers, on a consequential level, where one understands the causal relations between command and consequential performance, and on a dramaturgical

level. Thus, designing participation appears to be a rather complex task which comes with various demands. (cf. [1]) As for making the use of the 'tool' understandable to the audience, we designed a pre-performance which is described in the next paragraph.

LEARNING TO SWIM

In reference to J. Murray who in [2] describes that "in a participatory medium, immersion implies learning to swim, to do the things that the new environment makes possible", this paragraph explains how the audience of *Parcival XX–XI* was taught a lesson.

With the help of the pre-performance, everyone was given the chance to learn how to handle the provided interface, in our case Nintendo Wiimote controllers. These events included a 'Wii fairy', a jingle, a dancer on a diagonal wall, projections, and the audience. Every five minutes, the audience would be requested by a jingle, saying "it's time for intervention!" Miming, the Wii fairy would now show the audience how to use the controllers and sort out difficulties. Ultimately, the audience was taught two ways to use their Nintendo Wiimote controllers during the performance of *Parcival XX–XI*.

The first gesture (mote being moved down) would introduce a new clothing item to the diagonal wall. The performer would then adjust her body accordingly. The second gesture (mote steadily in front of the body) would remove all items formerly applied. Repeatedly practiced in the pre-performance, these two gestures would reappear in the main performance, only with different implications. The two scenarios of *Parcival XX–XI*, in which the audience is asked for intervention, are described in the next paragraph. Further discussions about to what extent the audience reached not only the technical but also the consequential and dramaturgical level of understanding follow in chapter 'Qualitative Research'.

TO SWIM

The first scenario includes four audience members, each charged with dressing one dancer and (therefore) undressing another. The catch: Only three clothing items are available for the four dancers – always leaving one dancer naked. Participants can use their Nintendo Wiimote controllers to either steal an item or securing their own item, sometimes resulting in inactivity of one or the other participant. The second scenario includes three audience members charged with controlling an avatar. These avatars fight against the dancers. Participants can use their Nintendo Wiimote controllers to either let their avatar attack or defend themselves. Whilst no text is used during *Parcival XX–XI*, the audience interaction operates with words. It is introduced by the jingle "it's time for intervention!" and the starting point of the interaction is marked by the projection of "3, 2, 1, go!". During the participatory scenarios, the words "Steal/Keep/You are already dressed!" (1st scenario), and "Defend/Attack" (2nd scenario) come along with the projections to deepen the understanding of the interaction.

Substantial to the dramaturgical aim of the participatory scenarios is the aspect of interaction within a closed and prescribed system. As we deal with social systems in *Parcival XX–XI*, such as communism or fascism, we wanted to design an experience for the audience, which makes them feel as a social subject. Our scenarios are thus created as an analogy to society – both constitute a closed system in which citizens are allowed only a limited amount of freedom of action, since they are given only a limited amount of options for action: 'dress/undress' and 'attack/defend'.

Qualitative Research

30 short guided interviews have been conducted with ten females and 20 males between 24 and 63 years old. Most interviews were held in German and are here translated by the authors. Interviewees were chosen by chance. For statistic purposes, name, sex, age and occupation were also collected. Each interview took between five and 20 minutes and implied the same three short questions:

1. Which aspects especially caught your eye?
2. How did you perceive the use of digital media?
3. How would you rate the use of Nintendo Wiimote controllers?

TO SINK

Evaluating these first 30 interviews, one decisive term recurs again and again: disruption. Regardless of their professional background, many recipients describe that they experienced the two participatory scenarios not as part of the performance but as disruption in form of a "a break-entertainment" (interviewee 1: int 1). According to the audience, these two sequences do not seem serious, more like an "audition" (int 2), or like „physical education" (int 3) – "a gimmick." [3] One woman even stated that – contrary to what the jingle presupposes – she does not experience the interaction as a real intervention but as "being degraded to a robot" (int 4). It thus seems, according to Benford et al., that the "performance's continuity is at risk," [4] during the participatory moments for several reasons. As paper length is constrained, we cast only a short glance on the following four: language, rhythm, limited exploration and shift of the spectator–role. Contrary, there are a few interviews of which we assume that disrupting the flow of a performance can also be seen as a promising design strategy, as here: "It was different to the rest, with the jingle, text etc., and this is exactly why I remember those moments best" (int 5). However, in this paper we will not provide an in–depth discussion about it but indicate that this topic leaves space for future work.

LANGUAGE

"(...) out of the sudden there is text and the jingle. It is confusing. It appears to be more separated from the rest of the performance than it was planned, right?" (int 6)

Various interviewees remark that first, the jingle „it's time for intervention!" and second, the written text of "3, 2, 1, go!", "Steal/Keep/You are already dressed!" and "Defend/Attack!" has set the participatory scenarios aesthetically apart from the rest of the performance. According to the audience, by using language, an emphasis is produced which does not find its analogy on the content side. Using text elements in our piece without language was an attempt to make the interaction clear, quick, and easily understandable for the audience.

RHYTHM

"These participatory moments are interesting, too, but not as smoothly integrated into the rest of the performance as it could be." (int 7)

Many people judged the participatory scenarios negatively as not fitting into the rhythm of the performance. The interviewees thus communicate an important element of contemporary dance: timing. From a dramaturgical point of view, the first participatory scenario is scheduled to an appropriate point in time. Before talking about the totalitarian system in the second act of *Parcival XX–XI*, we offer the following experience to the audience: The political system we live in does not happen to us but is chosen by either confirmation or non-rebellion. But choreographically, the first participatory scenario is scheduled to an inappropriate moment in time as it follows after a quite long scene without music and projections, focusing on the materiality of the styrofoam cuboids. At this point, the audience expects something very dynamic and energetic to follow. Instead, the jingle as an introduction for the first participatory scenario intensifies the stagnation to a break. Further, members of the audience have to step on stage, take their Nintendo Wiimote controllers and get in position. This all takes a while in which we often 'lost the audience'. To overcome this problem, we are considering rearranging the participatory scenarios in order to find an appropriate timing for *Parcival XX–XI*.

LIMITED EXPLORATION

"I was disappointed about the fact that only two gestures would cause any action!" (int 8)

The two gestures are often described as too simple, not opening any kind of freedom of action. Interestingly, nobody reflected upon the fact that we wanted to produce exactly this feeling of restricted action in a set system to further encourage individual solutions. In none of the performances of *Parcival XX–XI*, a spectator sought for solutions beyond the prescribed system to overcome the constraints: For example, for the second scenario one could have denied to fight, as a test person did in the general rehearsal or as interviewee 9 says, "we all could have acted more impulsively by e.g. falling down to the floor, as the dancers did". But they didn't. As the participants follow our rules, there is no other solution than 'playing' against each other.

Interviewee 8 and many others seem to not come across the technical and consequential level of understanding: Even though participating in the play, they can not produce further meaning for the context of *Parcival XX–XI*. They appear to be frustrated and disappointed about the limited freedom of exploration offered by the controller itself. In order to release the audience from this rather sidetracking technical aspect of how to handle the controller, we are considering changing the technology from Nintendo Wii-controllers toward a more self-explanatory option (such as camera-based tracking solutions, motion capture suits or Microsoft Kinect). However, all suggested options come with various other challenges which are, in fact, of a rather practical nature. (cf. [1])

SHIFT OF THE SPECTATOR-ROLE

"It is very boring to watch people in their winter coats, doing the same action over and over again!" (int 10)

Although the declared aim of the authors of *Parcival XX–XI* was to not create a traditional audience situation of 'leaning back in the seats', the audience described the participatory scenarios as a disturbance to the (seemingly!) previously established traditional way of watching. According to the spectators, on the one hand, they were pulled out of their coziness by the possibility to go on stage and 'play' with the Nintendo Wiimote controllers, and on the other hand, they were supposed to watch other spectators

(non-professionals) to act on stage which resulted in different reaction such as e.g. schadenfreude [cf. 5] or boredom (int 10). Similarly, Benford et al. [4] suggest that "beginnings must be designed to introduce the narrative, brief participants (...). It should be designed to be an integrated part of the experience." For *Parcival XX–XI*, we might have failed in taking the chance of the pre-performance to not only brief the audience how to handle the controllers etc. but also to introduce the main subjects of the play. We only teach the mechanism of the interaction as such and do not communicate relevant hints to the audience by means of dramaturgical impact for the experience of the play itself.

Benford et al. [4] further define traversals between physical and virtual worlds and temporal transitions between episodes as moments in which the flow of the play is on risk. These points clearly bring us to the major issue of our participatory performance as we invite members of the audience to not only progress from spectator to active participant and finally performer, (cf. [1, 6]) but we also expect them to fall back into their seats and lean back again after "they have done what we expected them to do" (int 11). One can say, we prepared the audience for the shift from a passive spectator to an active performer in the pre-performance but we 'forgot' to design the back-shift from a performer to a spectator. [7]

By the use of participation, we cause different categories of audience at the same time: passive spectators and active performers. This results in the fact that there are various opportunities to miss parts of the performance as one is moving between the passive physical world and the active virtual world. As *Parcival XX–XI* does not provide a linear narrative but works with fragmented atmospheric tableaux which are then free for interpretation to the audience, one could think that the above mentioned aspects are of no consequences (and we partly thought so). But one major problem here is that most people expect to be served a story with a beginning and an end. And as they do not get 'the explanation', they feel baffled. All other challenges, such as 'participating', seems to be the icing on the cake.

To be continued

Summarizing, we can say, that part of the audience does not experience our interactive quest as 'real' but as 'fake' by calling it a disruption of the 'real play'. Reflecting on why they felt disrupted in the flow of the performance, they name reasons such as the use of text in a fully textless performance, the wrong timing, the limited freedom of exploration with the Nintendo Wiimote controllers, and the shift of the spectator role in an otherwise traditional piece. Still, there is a small group of people that felt encouraged to participate and got caught by exactly the disruption as it appears contrariwise to what one would expect of the 'common flow of a performance'. We might need to ask ourselves how to establish a rather smooth frame of expectation to find the right moments to break with it again. In this context, and what comes for us with surprise, our advertisement campaign seemingly promised the audience a 'proper' story and more 'real' interaction. We thus have to look into the need of helping the audience to trust themselves in their reception – to strengthen them in being an emancipated [8] and postdramatic spectator.

SIMILARITY IN MEDIA CONTENT: DIGITAL ART PERSPECTIVES

Christian Frisson, Stéphane Dupont, Xavier Siebert & Thierry Dutoit

This essay examines how media content navigation by similarity can foster new practices in digital arts, blurring the boundaries between composing/performing, curating/authoring, creating/interpreting. With MediaCycle, a framework for browsing media databases by similarity, we created several prototypes: a website for browsing dancers' identities through video recordings, a collaborative dancefloor for music creation.

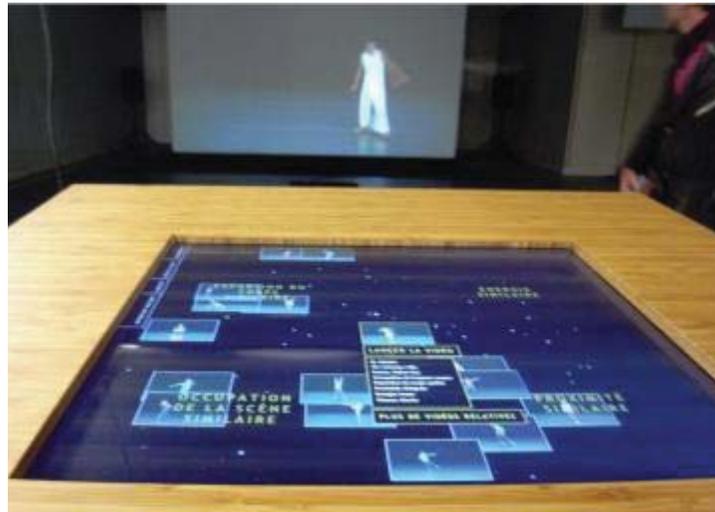

Fig 1. The DANCERS! Relational Browser seen on a multitouch booth.

Fig 2. LoopJam, a collaborative dancefloor for music creation

Introduction

Art and science cycle in loops: digital artists have been appropriating themselves technological advances in scientific fields such as telecommunication, signal processing and information visualization; while engineers and scientists are often inspired by concepts imagined by science fiction authors or fueled by artists trying to push the limits of these technologies when applied in their new media artworks. Beyond storage and transmission, one current limitation in technologies regarding media content is how to maintain an overall understanding of the information provided by each new media recording against the profusion and proliferation of newly-created and user-generated content. In his book *The Language of New Media*, [1] Lev Manovich stresses the importance of the "representation" of media objects in a database, how these are organized together as a mirror to the knowledge that these provide. When hypermedia links attempted to connect media objects one another into the world wide web through metadata and labels, the intervention of humans to annotate the massive data produced continuously is becoming more and more difficult. Recent progress in automated content-based analysis of media recordings opens new perspectives for structuring and navigating media databases, for instance by organizing the media objects by similarity.

Similarity in media content

THE CONCEPT OF SIMILARITY THROUGH (DIGITAL) ARTS

Besides the catchphrase "Similarities and differences..." used as a leitmotiv to begin the title of some essays dissecting specific art genres or styles, not much literature is centered around the concept of "similarity" in (digital) arts. Instead, an understanding of this concept can be grasped by focusing on specific uses of this term and peripheral vocabularies.

Literally, "similarity" names one of the Gestalt Laws in cognitive psychology: the human visual perception tends to discriminate outsider elements from groups in a visual collection. It has high implications in human-computer interaction and objector graphic design, such as how people can remember the content of a scene by gaining a structured knowledge of it, and how people can be attracted by objects or visuals that remind them of features of other objects they might have liked previously.

More specifically, humans have ever been fascinated by the complexity of natural phenomena showing repeating patterns: lightning bolts, clouds, tree-shaped vegetables, viscous flows. This concept of "self-similarity" has been inspiring fractal art, and is salient in paintings from Escher and compositions from Bach, as examined by Hofstadter. [2]

Each of both definitions, similarity as Gestalt law and self-similarity, underline one major aspect of similarity in media content: similarity can be used to characterize and compare several elements of a database (*inter-media*), and focus on the structure and contents of one single element (*intra-media*).

Several aspects of similarity can be used to describe the nature of artworks. First the relation of art to people: who originated it versus who keeps it alive in people's memories (the issues of authoring, composition, interpretation, performance, appropriation, inspiration, creativity, emulation, reproduction, recomposition, curation, restoration, preservation); second the relation of art works between them-

selves: what the work represents and how it place itself in a context of other works (identity, authenticity, singularity, resemblance). These concepts emerge in movie remakes (for instance re-performed or "sueded" movies in Michel Gondry's *Be Kind Rewind*), montages (Orson Welles' *F is for Fake*), collages (works of Jennifer and Kevin McCoy, Vicky Bennett aka People Like Us), cover bands and song covers (from re-interpretation to resampling with John Oswald's *Plunderphonics*).

How can organization by similarity of media content serve digital arts? Two tracks can be elicited from the aforementioned definitions and connotations: the first would consider the analysis, comparison, classification of existing art pieces; the second would focus on the generation of new art pieces based on content organization and navigation.

COMPUTATIONAL SIMILARITY

Computational similarity analysis consists in providing a machine interpretation of the salient characteristics of media objects, by applying feature extraction algorithms that downsize the data contained within the media into threads of specific information, and comparing the distribution of these features over a database using adapted distance metrics. Features can be content-based, that is extracted directly from the digital representation of the media object; or semantic-based, provided by manual annotation that labels specific elements of a scene. The book chapter from [3] provides a recent and detailed overview on the state-of-the-art of interactive representation of media databases, focusing on image browsing applications. It concludes mainly that most applications still miss a proper user-friendly interaction. Examples of higher-level content-based interpretation are identification of cover songs and style and genre detection for paintings.

Artistic works focusing on media similarity

Several end-user applications using content-based similarity have flourished recently, particularly recommender systems such as LastFM (<http://www.last.fm>), however artistic installations or works are more seldom.

Most notably, George Legrady's Pockets Full of Memories (2001-2007) [4] (see <http://www.georgelegrady.com>) make use of semantic-based similarity: both installation and formerly accessible online as a website, it uses the Kohonen self-organizing map algorithm to organize on a screen snapshots of everyday objects scanned by visitors in the installation, based on the textual description typed by visitors, thus proposing an emergent ordering since each individual induces her/his own perception of the object entered in the database that might differ from the visual similarities.

Martin Wattenberg's The Shape Of Song (2001) (see <http://www.bewitched.com/song.html>) proposes abstract visualizations in arc diagrams of the musical structure of hundreds of songs. Starting from MIDI transcripts of the musical pieces (sequences of notes defined by pitch, onset and duration), summaries are computed using the maximal matching pair algorithm and other rules to reduce the complexity of this algorithm. These summaries are visualized using overlaid semi-circular arcs whose thickness corresponds to the duration of the repeated musical passages, therefore incidentally underlining their relevance. Several non-interactive printouts of these arc diagrams have been exhibited at the Generator.x 2005 art event in Oslo, Norway.

THE MEDIACYCLE FRAMEWORK AND ITS ARTISTIC INSTALLATIONS

MediaCycle (<http://www.mediacycle.org>) is a software framework for organizing media content by similarity. Since 2008, it has been developed towards a modular architecture, supporting several media types (so far: audio, image, video, text), various media-specific algorithms for content-based low-level feature extraction, plugins for clustering (particularly the K-Means algorithm) and positioning media elements in a 2D space. Designed deliberately cross platform using open-source libraries, it was initially targeted for major computer operating systems (Apple OSX, Linux such as Ubuntu and Microsoft Windows), and more recently for mobile platforms (Apple iOS and Google Android). It provides exemplar single-media standalone applications for desktops and laptops, and server/client applications for mobile devices and servers in the cloud. OpenSoundControl (OSC) networked communication support has also been added (see [5]) so as to control the navigation in media content using off-the-shelf devices such as jog wheels and 3D cameras.

The DANCERS! Relational Navigator

Choreographer Bud Blumenthal's DANCERS! project traveled in Belgium and France in 2009 and scheduled shootings to audition dancers by recording them with top and front cameras while they were asked to improvise dance moves on music played back without choreography. The DANCERS! installation is composed of a multitouch booth where the public can select dancers videos to be displayed on a video projector at the original body scale, with surround sound. Dancers videos are selected using the DANCERS! Relational Browser that is also available online (<http://www.dancersproject.com/interactive/>) and is powered by the MediaCycle framework. Videos were automatically analyzed so as to provide a content-based 2D representation of dancers groups sorted by features such as: position (mean, standard, max), speed, ratio of the dancer bounding box and contraction index, space occupation and trajectory (small/large, compact/sparse, proscenium/rear as preferred zone). This installation provides an interactive and alternative way of browsing through dancers videos beyond retrieval through standard metadata such as artists names. This work has been described in more detail in Tardieu et. al. [6]

LoopJam, a collaborative dance floor for music creation

In 2011, we proposed LoopJam (see <http://www.numediart.org/demos/loopjam>), an interactive installation that features a sound map with audio loops organized by similarity of timbre using MediaCycle and a Microsoft Kinect depth-sensing camera so as to map the visitors' positions to cursors on the map hovering sounds with audio feedback, loops being synchronized in terms of tempo by the sound engine. A few people from the audience can thus carefully select sounds and collaboratively create an "improvised music composition". Organization by similarity proves itself to be useful since audio loops from similar instruments tend to be grouped together, hence small movements of visitors would provide a slight variation in terms of content in the sound rendering. This installation revisits the artist to audience relation and interaction since the DJ or curator of the installation responsible with choosing the sound library to be browsed within the installation can select her/his trademark sounds conveying a personalized musical identity.

Conclusions and perspectives

This paper provided a brief overview of artistic works making use of content- or semantic-based organization by similarity of media databases. Two main disciplines are seen as beneficial from requiring media content similarity: media preservation and documentation, and (realtime) media recomposition.

The described works use one single media type for the content-based analysis. Combining features from multiple media should enhance the robustness of the representation, for instance using both the video and soundtrack in the case of film documentation so as to analyze the relation between image and sound, in parallel to expert interpretation models, [7] using interactive summaries. Similarly, when classifying music albums, the visual artworks from the album, the textual description, and the lyrics might add be relevant as well to sort and organize a collection.

Regarding media recomposition, alternative and engaging interaction methods might be investigated to browse media collections in realtime (particularly for DJs and VJs), such as query by sketching to retrieve visual elements from a database while drawing, or query by whistling or beatboxing to create musical content. These practises will certainly take advantage from advances in scientific fields such as multimedia information retrieval.

Acknowledgments

The authors have been supported in a great extent by the numediart long-term research program centered on Digital Media Arts (<http://www.numediart.org>), funded by Région Wallonne, Belgium (grant 716631). The authors wish to thank other past, present and indirect contributors to the MediaCycle framework, particularly Damien Tardieu, Thierry Ravet and Julien Leroy.

TECHNO VIKING - A CASE STUDY FROM THE WEB 2.0

Matthias Fritsch

For the last years Media Artist Matthias Fritsch was researching the Internet career of his widely known Internet Meme Techno Viking. In 2011 around 40 million clicks in various platforms and more than 3000 direct video responses can be counted. Technoviking is a entertaining and bizarre example of todays web-culture that represents the many form of user's approached to appropriate and recycle material at the web.

The Techno Viking Archive by Matthias Fritsch

THE CONTEXT

The Techno Viking project is an example for the reordering, reediting and remaking of an „original“ video in the internet. The original video is in analogy to genes called a meme. As such the original and its first clones, start to circulate within social networks, where the original mutates, competes with other originals and inherits. Becoming multiplied in this way, the original video becomes successful by reproducing itself, through various recycling techniques.

In this way the Techno Viking project questions the creation's origin of such an internet hype. The popular result is not the beginning, but the the original + n, after being altered and filtered several times through a chain of actions and reactions.

The potential of public attention such clips raise, brings also attention to the role of such major companies as Google. Google as the owner of YouTube provides the basic technological structure not only to enable and control, but also to profit from such creations. If the creation is based on “free” social information networks, the product is commercialized through a monopole company. In this way the Techno Viking is a perfect example to illustrate such new ways of production and distribution within user generated networks.

THE TECHNO VIKING

The Techno Viking is a tall, muscular, charismatic, intimidating German man in his 30ies, that danced in front of the camera at the Fuckparade in Berlin in 2000. The Fuckparade emerged as a reaction to the music restriction (e.g. the exclusion of other techno styles as Gabber, Speedcore, Hardcore Techno or Punk music) of the Berlin Love Parade and its increasing commercialization, as well as a public demonstration against the shut down of the famous techno club "Bunker," (which serves as a home for a private art collection today.)

The Techno Viking became famous firstly through the "Kneecam" video. A girl with heavy blue dyed hair is dancing to the rough techno beats, while a rather unruly looking guy, crashes unfriendly into her. That accident is causing the Techno Viking to demonstrate his physical power. He snatches the guy's arms and pushes him back from where he came dancing from. Pointing straight at another man and dominating him with his fiercely glance the Techno Viking produces an aura of fear, which brings the man to leave the situation. Only that incident enables the Techno Viking finally enough space to start dancing freely. His dance moves are wild and expressively but perfect in form. Soon he seems like the king of the street, having even fans, serving as “pop servants,” supplying him with water bottles.

At You Tube the fascination with the Techno Viking is expressed in several statements. One of the most famous lines started to reappear with the countless remakes of the “original” footage itself: “The Techno Viking doesn't dance to the music, but the music dances to the Techno Viking.”

After the most popular definition of Techno Viking [published by Mister Neutral on the Urban Dictionary](#) that 3041 people liked and 55 hated in November 2011 [1].

THE TECHNO VIKING ARCHIVE

The original 4 min video „Kneecam No.1“ was discovered in 2007 by the YouTube community and posted by users in various other platforms. After being linked and discussed in different web sides and internet forums, the footage got uploaded on www.break.com, a big american media portal. On this web side with a clear focus on a male audience – the video had it's peak on September 28th, 2007. Almost two million viewers were looking at it in only one day. Within the following 6 months more than 10 Million people were watching the video under it's new name "Techno Viking." In 2011 the clips overall attention counts around 40 million clicks in various platforms and more than 3000 video responses that directly connect to the original clip.

I was following those developments with great interest and researched the internet history of the video. In this way I documented its trajectory from its original production until it became a popular internet video multiplied by countless memes. The archive of the Techno Viking contains of emails, blog and

forum discussions, merchandising products and a selection of some hundreds of categorized image and video responses. To give an inside view on the career of the video and to show recycling strategies at Web 2.0 the archive is presented in form of installations and lectures. The archive contains around 8 GB of data and can be shared on request for further research and recycling ([contact](#)).

USER EXAMPLES

Following a selection of the most interesting and popular video responses:

Shortly after the main hype moderated clips were created to provide information about the new meme. A mixture of statistics, quotes and jokes make it easy to consume the semi documentations as the one from „Rocket Boom“ [Know Your Meme - Technoviking](#)[2].

Another moderated clip from the internet television channel „Revision3“ introduces a video response to the Techno Viking with subtitles as a new cult video itself: [Technoviking on Revision3](#) [3]. The clip refers to the [captured version of Techno Viking](#) [4] from YouTube user „rawcore“ that reached more than 5 million viewers on YouTube, [www.break.com](#) and other platforms.

But the most interesting genre of recycling memes is the re-enactment of the clip’s dramaturgy by being recreated in private and public space all over the world. A remix of more than 50 re-enactment Videos is published under the name “[We TechnoViking](#)” [5].

The peoples fascination with Techno Viking’s dancing skills create group choreographies as the [PSU Techno Viking](#) [6] or the one from the [AE Thesis Lab](#) [7] where a group of students is exercising the dancing technique.

The Techno Viking character even finds his way into the 3D worlds like [here](#) [8], where the Techno Viking like character „Mattias“ from the shooter „Mercenaries“ was animated to the exact dance moves of the meme or a [virtual re-enactment in “World of Warcraft”](#) [9].

The combination of one meme with another can raise the attention within the fan community and creates an overlapping mass to other internet hypes. Here it is throughout the use of Vernon Koekemoer and Chuck Norris in a „Streetfighter“ lookalike clip “[Technovikiung vs. Vernon Koecemoer](#)” [10] ...or the collages with „[Little Indian Boy](#)“[11] or [the main character of the cult movie „300“](#) [12].

The users by far biggest recycling strategy is the simple change of the soundtrack without doing much with the videolayers. There the Techno Viking clip was combined with all kinds of music genres like [metal](#) [13], [folk music](#) [14], [80ies classics](#) [15] etc.

AFTER TECHNO VIKING

From my experience with the TechnoViking phenomenon and by using the user's most popular recycling strategy I developed the Work „[Music from the Masses.](#)“ [16] Following a five year schedule I started to publish silent movies in the internet along with an open call for composers, musicians, sound designers and everybody else to create soundtracks accompanying the silent clips. The submitted contributions are published in the web in combination with the video as music clips. The work is an open edition and

will not have a calculated end. It will be furthermore possible to always add new compositions and variations. This generic model of recycling and resembling is producing a situation that can be called "Youtube-Reality." It is a reality where the setting of an original identity is in constant and uncontrollable aesthetic modification.

MOBILE TAGGING AS TOOLS FOR AUGMENTED REALITY

MARTHA GABRIEL

The objective of this paper is to describe the potentialities of Mobile Tagging (2D barcodes like QRcodes) as a tool for increasing and spreading the effects of Mixed Realities in Art. In this sense, we will start introducing the main concepts and some examples of Mixed Realities followed by the concepts and examples of Mobile Tagging, showing that they are connected and benefit each other.

INTRODUCTION

The objective of this paper is to describe the potentialities of Mobile Tagging as a tool for increasing and spreading the effects of Mixed Realities, including in the field of Arts. In this sense, we will start introducing the main concepts and some examples of Mixed Realities followed by the concepts and examples of Mobile Tagging, showing that they are connected and benefit each other.

Mixed Reality (or MR) refers to the fusion of the physical and virtual worlds to produce new environments and visualizations where physical and digital objects co-exist and interact in real time. On the other hand, mobile tagging is the process of reading a 2D barcode using a mobile device camera. Allowing the encryption of URLs in the barcodes, the mobile tagging can add a digital and/or online layer to any physical object, providing so several levels of mixed realities related to that object.

The uses of these levels of mixed realities have applications in several areas going from medicine and engineering to arts. This paper/presentation will use some artworks as examples to illustrate the functionality of the mobile tagging for creating mixed reality.

MIXED REALITY

According to the Virtuality Continuum concept (MILGRAM, 1994), the mixed reality is anywhere between the Virtual Environment and the Real Environment, comprising stages of reality, augmented reality, augmented virtuality and virtuality.

Examples of Virtual Reality are the immersive caves, where the interactor dives into the virtual environment. Some examples of mixed realities applications are:

- MINI Cabrio – car advertisement (Youtube, 2009-2).
- SPOILER - game (Youtube, 2009-1).
- BMW - engine maintenance (Youtube, 2009).
- Arcane Technologies - educational and military applications (Arcane, 2009).

Several kinds of devices and technologies can be used as tools for mixed realities, such as glasses, gloves, monitors, computers, cameras and mobile devices (PDAs and cell phones). Due the pervasive nature of the mobile devices, their potentiality for increasing the dissemination of mixed realities is enormous and can be leveraged by mobile tagging as described next.

MOBILE TAGGING

Mobile tags are 2D-barcodes that can be scanned by mobile devices in order to decode the information kept in the barcode.

There are many types of 2D-barcode (tag) and it is possible to encrypt many kinds of data into them. However, regarding mobile tagging, the most common encrypted information is URLs. The process of mobile tagging consists of scanning the tag with a mobile device camera using a mobile tag reader, which decodes the tag, opening the decrypted information on the device screen.

The most used patterns of 2D-barcodes for Mobile Tagging are QR Code (Quick Response Code) and Datamatrix. While conventional bar codes are capable of storing a maximum of approximately 20 digits, a QR Code, for example, is capable of handling up to thousand characters and all types of data, such as numeric and alphabetic characters, Kanji, Kana, Hiragana, symbols, binary, and control codes (Denso-Wave, 2009).

According to (Denso-Wave, 2009), the capacity of storage of a QR code is:

QR Code Maximum Data capacity

Numeric only - 7,089 characters

Alphanumeric - 4,296 characters

Binary (8 bits) - 2,953 bytes

Kanji, full-width Kana - 1,817 characters

Nowadays, although mobile tags are still a novelty for most of the countries, they are starting to spread as the 3G mobile technology get available around the world. The QR codes use is very common already in Japan and Datamatrix is more used in Europe, especially in UK. Most of the new models of mobile devices come already with the mobile tags (QR code and Datamatrix) reader. Older versions of devices can install a QR code reader, such as i-nigma (www.i-nigma.com), becoming so able to scan them.

A very interesting use of mobile tagging as mixed reality is the Semapedia.org (www.semapedia.org) that stimulates the use of in physical places that are present in the Wikipedia, mapping them. In this sense, each place is provided with a new layer of dynamic information coming from the digital online world, increasing so their use.

MOBILE TAGGING IN ART

There are several interesting examples of exploring mobile tags in Art. We will present three artworks using QR codes that range from traditional arts to electronic interactive arts. The first example is the work STILL by Frabrice de Nola (2011) that uses 2D and liner barcodes to build the image and links.

We can mention as one of the first interactive digital artwork the SENSITIVE ROSE (Gabriel, 2008) artwork, which builds an interactive compass rose formed by QRcodes that navigates into people's desires (figure 1). The work is a big projection (3 meters x 3 meters) and all the interactions happen through this projection by scanning the dynamic QRcodes for participating. The work was launched in November of 2008 and has received already more than 800 interactions (May.2009).

Figure 1 – Screenshot of the artwork Sensitive Rose (GABRIEL, 2008)

Another interesting artwork that uses QRcodes is the "Suite 4 Mobile Tags" (Beiguelman, 2009) which proposes an exercise of random and anonymous collective musical composition. By pointing a phone w/ QR-reader to a display, participants play a ringtone. The result is a sudden and temporary suite that plays with hi and low tech, the portability, the confusion between public and private, music and noise.

CONCLUSION

Since the mobile tags are simple tags that can be placed in virtually any physical object or person, added to the fact that the cell phones with camera have become a very inexpensive and pervasive device, the mobile tagging process can be said as one of the easiest and simplest way of creating mixed realities.

The use of mobile tagging can range from expanding the information on packages, bus stop routes, museum objects, to art.

Mobile Tags work like physical links to the web, allowing so that virtually anything can be part of an expanded mixed reality environment.

THE ELECTRONIC REPRESENTATION OF INFORMATION: NEW RELATIONSHIPS BETWEEN THE VIRTUAL ARCHIVE AND ITS (POSSIBLE) REFERENT

Gabriela Galati

Screenshot: <http://www.googleartproject.com/museums/met>

The present work focuses on the new relationship generated by electronic information between the virtual archive (the Web in a broad sense, certain specialized archives in particular) and its referent (material reality in general, museums, inter-art practices, and artworks in particular).

What Nam June Paik conceived as a shift from the telecommunications network to a “multilevel digital communication network” is now taking place at a highly accelerated pace with vast unexpected consequences and possibilities for the artistic field. Moreover, it has also a close relationship to what Manuel Castells [1] defined as the “space of flows” or “real virtuality”.

“The space of flows” is the abstraction of time and space and their dynamic interactions within digital age society. Castells developed this idea to “re-conceptualize new forms of spatial arrangements under the new technological paradigm”; a new type of space that allows distant synchronous, real-time interaction.

“The space of flows” can be experienced right now, a “multilevel electronic communication network” in which anyone can access from home not just of a website, but also the 3D photographic representation of a certain place, the street view of her/his house, of a friend’s house, of a possible place to rent, or of a museum. This access is also making the distance between remote places seem inexistent in a certain way.

This concept opens several questions, for example: how is this representation presented? How is this possibility of accessing a physically distant place in all its details, without actually being physically there, affecting the ways in which this space is perceived?

In this regard, the electronic elaboration of the representation of information suggests following new paths, not only to deal with massive amounts of data, but also to better penetrate the domain of knowledge that every person should possess [2].

Moreover, the forms this representation of information takes are closely related to the ways in which its perception is structured and shaped. As Manovich [3] puts it "by organizing computer data in different ways, the interface provides different visions of the world". Therefore, the relationship between information, its representation and the referent (or in other words, the relation between reality and the conceptual construction of reality) has to be re-thought.

As many theorists advanced, this representation does not need to be-in-the-place-of a 'physically existent' entity, and that is why the referent is only 'possible'. Postman (1985) defines *virtual* as being so in practice though not strictly or in name; and *real* as actually existing, and advances that

"We don't see reality as it is but as our languages are. Our languages are our media. Our media are metaphors. Our metaphors create the content of our culture." "There is no separation between "reality" and symbolic representation. In a way, all reality is virtually perceived." [4]

Virtual or real, this digitalization is changing the status of the digitalized works, at the same time that influences our perception of them. In the same way language and metaphors build our 'reality' or structure our perception of the world, the Net as a text influences our perception of material reality, and the ambiguous nature of language has to be taken into account in this respect.

Thus reality, as experienced, has always been virtual because it is always perceived through symbols that frame practice with some meaning that escapes their strict semantic definition.

"A system that generates real virtuality is a system where reality itself (people's material/symbolic existence) is entirely captured, fully immersed in a virtual image setting [...] in which appearances are not just on the screen through which experience is communicated, but they become the experience." [5]

In this sense, a virtual presence is not less real than a material one, so where does the difference reside?

Following Levi-Strauss' [6] statement that the inadequacy between the signifier and the signified is the cause of every mythic and aesthetic invention that were aimed to cover this flaw, or this unfitness; it is possible to think about the inadequacy between the virtual archive and its (possible) referent in these terms. It is necessary to try to understand what is happening with this non-fit, or overspill, and accordingly, what is happening in the gap, in the "inadequacy" between the virtual archive and the physical museum. This overspill can be considered the intrinsic ambiguity of symbolic production. Moreover, the very well known impossibility to "translate" symbolic productions is what generates the change of the ontological status of digitized work.

In his article "The Archive Without Museums," Hal Foster [7] advances the hypothesis that photographic reproduction allowed a new "dialectics of seeing," represented by the positions of Walter Benjamin: namely, that photographic reproduction strips art of context and aura, and therefore its cult value and exhibition value are lost forever. In contrast, André Malraux claimed that the museum guarantees art as such, and photographic reproduction offers the means to put together "the bits and pieces" into the meta-tradition of "style".

If the museum guarantees the status of art and photographic reproduction permits stylistic affinities, what might a digital reordering encourage?

It is possible then that electronic information and digitalization establish new dialectics in which a museum's legitimating function is replaced by the virtual archive and/or museum/gallery websites.

It could be also said that some artworks are being produced solely to exist for the virtual archive? Moreover, has the time come when on-line documentation of exhibitions that never happened are created and presented?

At the same time, as Bolter and Grusin [8] advanced about the process of *remediation*, the influence goes both directions: from the virtual to the material, in the ways artworks are documented, affecting the processes of legitimization and probably also of production; and from the material to the virtual, when the virtual is anchored to reality in the imitation, or realistic representation of it (specially three-dimensional space).

Without falling into *modernists* positions about 'the intrinsic' possibilities of each medium, could we find a way in which the new archive can deal with art without imitating physical reality in the display? By taking the most profit of the hyperlink logic, and thus of the "overspill" and of ambiguity, can we create a non-linear, more experimental and open archive in which each user could ideally build her/his own path through it? It has been discussed if this 'freedom' of choice provided by the hyperlink logic and the virtual database is only an illusion or an utopist idealization of the medium. Even if not unlimited, this possibility exists and the medium undoubtedly offers a considerable degree of "personalization" in the paths to follow through a certain database or archive.

The shift Foster talks about is from the perception of the world as an image, to the codification of the world, and these images included, that result into pure information.

"[...] the humanism of the world-become-picture may reverse into the inhumanism of the world-become-information. For in the virtuality of the archive [...] what is real is not what appears at any moment, but what is conserved in memory [...]" [9]

In the same way the object is digitized in the archive, the medium loses its original materiality to be converted into a pure image. By being absorbed and re-generated in the virtual database, its status changes to the one of an "image-text", or of an "info-pixel".

This is the reason why the virtual archive no longer needs a physical referent. It doesn't mean that it has been removed from all physical support, only that the support of the information (memory and database), which constitutes the object's new "materiality", does not coincide with the support that presents it to be seen and apprehended (a screen). Therefore, even if the referential relation is not completely annulated, it becomes weaker and fragmental [10]. The iconic sign, in Peirce's terms, still maintains its relationship of resemblance with the object, but the medium has been converted into an image-text, and info-pixel [11]; its materiality has been 'translated' into information, into a code.

This new database is generating a dematerialization of memory and its record. However, this dematerialization is not the same proposed by the Conceptual Art of the '60, this is a somehow 'new' dematerialization, which does not imply an annihilation of the object, but just a change in its ontological status.

PARTICIPATING IN PARTICIPATION: POLITICS AND CITIZEN POWER

SEETA PEÑA GANGADHARAN

This paper applies a seminal critique of participatory politics written in the 1960s in relation to modern day experiences of citizen participation. Arnstein's writing on "participating in participation" unmasks the superficiality of online participatory projects and practices.

Participating in participation: Politics and citizen power

In the United States, the past decade has been marked by an optimistic discourse about the technologies of political participation in American government. But what power have these tools created? Drawing from earlier criticisms of participatory democracy, this paper provides evidence that citizens are doing little more than participating in participation. Until innovative participatory designs happen alongside commensurate changes among political powerholders, online participation will represent more of democracy's failures than its achievement.

A new wave of optimism

In 2009, the Obama Administration arrived to Washington, D.C., amid a wave of optimism about tools for online participation. Throughout the 2008 election, the Obama campaign developed MyBarackObama.com, a social networking platform designed to engage interested voters and provide them with tools for enlisting volunteers and generating support (Kreiss 2010). In the months before taking office, President Obama and his transition team launched a *Citizen Briefing Book*, a website that invited ordinary citizens to register their hopes and proposals for the Obama Administration and rank individual entries. Shortly after taking office, President Obama declared: "My Administration is committed to creating an unprecedented level of openness in Government." [1]

Illusory involvement

The zeal with which the Obama Administration has embraced online participation is an invitation to reflect on when and whether participatory designs equate with citizen empowerment. As early as the 1960s, observers questioned the gap between participation and influence, suggesting that citizens and communities would remain disempowered if powerholders simply celebrated participation as having happened. Among the most persuasive of these was Sherry Arnstein, a health policy expert involved in community development projects around the country.

In 1969, Arnstein synthesized her experiences into a short critical essay. *A Ladder of Citizen Participation* looks at the palliative effects of participatory projects. According to Arnstein, a significant problem with designs for participation is that they are more concerned with offering participation than taking citizens' concerns seriously. She described that most citizens are invited into policy debates for their appearances rather than for their ideas or to move along debate and influence outcomes. Participants in these scenarios are manipulated by "powerholders... [who] "'educate' or 'cure' the participants" (Arnstein 2003, p. 246) of their problems. As a result, "What citizens achieve in all this activity is that they have 'participated in participation.' And what powerholders achieve is the evidence that they have gone through the required motion of involving 'those people'" (247).

By contrast, Arnstein said that the most laudable form of participation occurs when “have-not citizens obtain the majority of decision-making seats, or full managerial power” (Arnstein, 2003, 247). In other words, successful participation is measured by the extent to which outcomes reflect the concerns, arguments, or proposals of citizens. Arnstein's critique focuses on the substance of citizen participation and the ability for citizen input to move public policy. From her vantage, citizens require a direct means of transforming political outcomes. Failure has scarred “every other means of trying to end the powerlessness” (Arnstein 2003/1969, 246).

When viewed in relation to the routines and demands of American society, Arnstein's push for direct democracy is far from pragmatic. As Young (2006, 2000) argued, the complexity of modern society deters the kind of decision making that Arnstein envisioned. The type of direct democracy implied by Arnstein's critique entails coordination and cooperation of a degree that large, diverse countries like the United States would find nearly impossible. Modern democratic societies demand a system of political representation so that citizen *ideas* and *arguments* have power within political discourse and influence political outcomes. Nevertheless, modifying Arnstein's call for direct democracy does not diminish the persuasiveness of her main argument: participation which is staged for performance, for ticking off a box that indicates participation has happened, does nothing to change structures of power in the political landscape.

Participation's promises and failures

The problem of "participating in participation" unmaskes the superficiality of much of the promise of on-line participation in electronic government. One example of the illusory participation are the "reboot" efforts of the Federal Communications Commission (FCC). The FCC is the premier regulator of media, communication, and information in the U.S. It creates policies related to the management, ownership, and operation of wireless and wireline communication systems.

When Chairman Julius Genachowski was appointed to the head of the FCC, he pledged to fight for consumers and transform the agency into an “21st century agency for the information age” (Genachowski 2009, 3). He focused participatory reforms on creating new online tools to welcome citizens to the virtual front door of the agency. Soon after his appointment, the agency set upon a path to reform of the electronic means for public participation. From live-streamed, captioned video of its public meetings to a redesigned entire website, to staffers' blogs about their work to a YouTube channel and Facebook page, the FCC broadened its online presence. The agency also created mobile apps that users could install in order to test home broadband speeds began tweeting announcements of its most controversial policy proceedings. Improving public access was paramount in agency that had "communications" in its middle name, according FCC managing director Steven VanRoekel (Howard 2010).

The comprehensiveness with which the FCC has gone about implementation of new forms of online participation is impressive on paper. Within two years, the agency has cultivated a set of digital tools to push and receive information to ordinary individuals and communities. It drew accolades from technology-focused blogs and news services, like *O'Reilly's Radar* and *Ars Technica*. On its own blog, the agency boasted of its innovative efforts, stating that the FCC was “[p]utting citizen skin in the game to make FCC.gov work better for users, and holding us accountable to continual improvement.” [2]

Apart from accolades, however, the FCC's record on serving citizens and consumers reflects very little of its talk about empowerment of the non-expert, lay participant in communication policymaking. The

most controversial decisions that have come before the agency since 2009, when Chairman Genachowski came to power, are an ode to conventional, “inside-the-Beltway” policymaking than transformation of FCC culture. The FCC's *Open Internet Order* (2010) concerned the extent to which telecommunications carriers can discriminate in how it manages data traffic over the internet. The decision handed down by the agency excused mobile carriers from anti-discrimination measures, paving the way for price changes in mobile internet access.

The proceeding saw more than 100,000 commenters, many of whom included citizens and their representatives, such as media reform groups, public interest organizations, and community associations. As Arnstein would have predicted, these commenters were recognized not for the arguments they registered with the agency but for the fact of having happened. The final report and order made little attempt to extricate the complexity of the opinions and arguments raised by ordinary opinions. Neither did it seek to answer explicitly to a discourse of concern over industry-friendly internet regulation.

An announcement by Meredith Atwell Baker, one of the commissioners who had voted for lenient internet rules, suggests that participatory reform was a weak proxy for citizen power. Four months, Baker left the FCC to become the chief government relations person for NBC-Comcast, a major supporter of lenient data traffic management rules. Before it had merged with NBC, Comcast led a legal battle to weaken the FCC's ability to institute anti-discrimination rules for internet providers. Baker's move evidences the extent to which government and corporate powers mutually support one. The nexus between state and market deters the ideas of ordinary people and their hopes for how democratic society ought to be governed from having a fair chance of being heard and influencing political outcomes.

We participate, they profit

In the original 1969 publication, Arnstein accompanied her critique with an image of a poster taken from the 1968 student uprisings in Paris. Translated into English, the poster read, “I participate, you participate, he participates, they participate, we participate... they profit.” In an era where digital tools for participation abound, government and corporate powers are still profiting from the citizens' involvement in decision making. It legitimates their activities, shows that participation has happened as a matter of procedure, and masks the need to engage with the proposals or demands contained within citizen expressions. Until state and market actors transform how they interact with one another and either intentionally or unintentionally collude to minimize the power of citizen voices, American politics will fail to live up to basic democratic ideals.

'WOODEN WORLDS' - AESTHETICAL AND TECHNICAL ASPECTS OF A MULTIMEDIA PERFORMANCE USING REAL-TIME INTERACTION

Javier Alejandro Garavaglia & Claudia Robles Angel

Wooden Worlds is an audiovisual, interactive performance by Claudia Robles Angel and Javier A. Garavaglia. The piece, of variable length, is a complex multimedia performance in which viola, video, photography, soundscapes, live-electronics and live processing of pre-recorded sounds interact with each other in real time, all of which intersect in art, science and technology. The paper describes the technical and aesthetical aspects of the work.

Figure 1. Examples of close-up images from tree cortices in 'Wooden Worlds', 2010, Claudia Robles Angel, photographic media, Copyright Claudia Robles Angel.

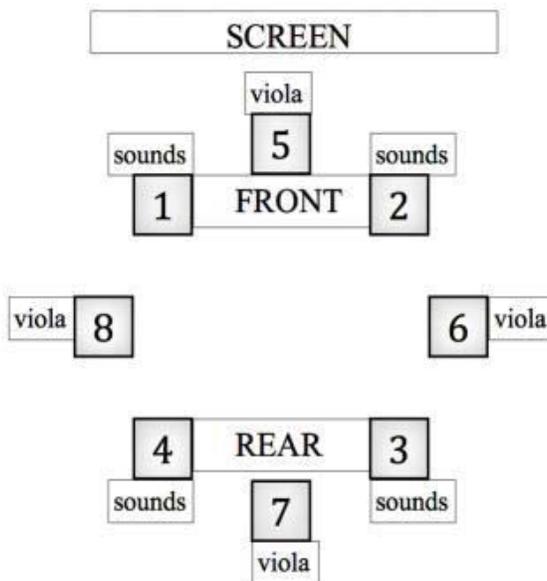

Figure 2. Octophonic sound distribution for 'Wooden Worlds'.

INTRODUCTION—AESTHETICAL ASPECTS

This paper describes the intention, aesthetical principles and technical aspects of 'Wooden Worlds', an interactive audiovisual performance by Claudia Robles Angel and Javier A. Garavaglia. The piece is a multimedia performance developed from several different sound and visual layers, all of which interact with each other in real-time. Together they create an atmospheric constellation. The attention of the audience is challenged by the piece's audiovisual elements, which in most of the cases are not recognizable at first sight. The role of the viola live on stage acts as an element of synergy between the diverse audiovisual elements, with musical composed and improvised passages. The performance requires two computers on stage running both the software package MAX/MSP/Jitter for real-time interaction.

The piece works with a world of sound and image, which is directly or indirectly connected to wood, particularly, in the way wood appears in nature, namely, in the form of trees or of tree cortices. Nevertheless, the idea is not only to show wood in its naked reality, but also to use images and objects of particular forms and characteristics, which, whilst made of wood, cannot immediately be recognised. One of the techniques utilised herewith is that of the 'close-up,' which consists of the shooting of surfaces at an extreme proximity, resulting in pictures showing those surfaces in a meticulously detailed manner. The resulting images, normally called 'close-up photography' or 'macro photography,' are usually shot by zooming or, most likely, by the usage of macro lens. In 'Wooden Worlds', this technique is utilised to show extremely close details of wooden surfaces, which, in many cases, are not recognisable as such at first sight. The intention is to produce a 'haptic' image, in which the observed object can be de-contextualised, allowing a free and open interpretation by members of the audience, who can have the feeling of 'touching' the images with their eyes. The word 'haptic' has its root in the Greek word HAPTOS (ἅπτω), which means to touch or to fasten. This type of visual conception is a fundamental aesthetical position of Claudia Robles Angel, one of the authors herewith, who seeks to transport the tactile sensation to the photographic image, approaching the object as much as possible, thus inviting to use the eyes to feel and not only to see. This usage of the word 'haptic' in visual arts (image and moving image) has its roots in Deleuze: [1]

"Where there is close vision, space is not visual, or rather the eye itself has a 'haptic', non-optical function: no line separates earth from sky, which are of the same substance; there is neither horizon nor background nor perspective nor limit nor outline or form nor center; there is no intermediary distance, or all distance is intermediary."

Following this interpretation by Deleuze, the term 'haptic' is not used in 'Wooden Worlds' in the same sense as in 'haptic interaction', which is the type of interaction produced by touching devices, as defined by Hermann and Hunt. [3] The usage of the term in this performance is implied aesthetically, with no reference whether to the interaction itself, nor to the interfaces used, as no interaction in this piece occurs by the act of touching devices or interfaces. By making possible to 'perceive the imperceptible' through 'haptic images', the audience is immersed in a virtual space of images and surround sound, in which the material 'wood' is constantly alluded to.

The sound components in 'Wooden Worlds' have two sources: (a) pre-recorded concrete sounds and (b) a live viola on the stage, mixing fully composed passages with improvisation. The pre-recorded sounds were obtained during nightly recordings of the rainforest in South America. The richness of this nightly

natural 'soundscape' was paramount to the general sound conception of the piece, as it helps the listener to become part of the immersive virtual environment of the performance. The concept of 'soundscape' is herewith referred to as defined by Truax: [4]

"A soundscape is an environment of sound (or sonic environment) with emphasis on the way it is perceived and understood by the individual, or by a society. It thus depends on the relationship between the individual and any such environment. The term may refer to actual environments, or to abstract constructions such as musical compositions and tape montages, particularly when considered as an artificial environment."

This feeling/sensation of a natural sound-dome inspired the acoustical space in 'Wooden Worlds,' which, while still following the generic description of the term by Truax [4] (quoted above), creates an immersive environment during the performance by transforming those sounds in real time instead of making 'a musical composition' or a 'tape montage' as in Truax's definition. [4] The soundscape idea in 'Wooden Worlds' is technically aided by the octophonic sound, which surrounds the audience in the complete darkness of the concert venue creating a unique atmosphere between natural and virtual environments.

The form of 'Wooden Worlds' was conceived as an arch, with a climax at its golden mean. The usage of the golden mean creates the impression of a quasi-biological cycle, which begins and ends in complete darkness with the same type of audio material (insect sounds), but which evolves towards a climax, in which all forces interact, fading gradually out to complete darkness in the last third of the piece.

1-INTERACTION ASPECTS

The interaction of the piece was programmed in three dimensions: (a) live-electronics, (b) video interaction with the viola, and (c) interaction via a MIDI controller. The two laptops must connect (both with a different fixed IP address) with each other via Ethernet using the MAX object 'udpsend.' The first computer acts as the master, generating SMPTE Time-code, which is then transmitted to the second computer for synchronisation purposes. The master is in charge of several DSP functions for the viola's live-electronics. The second computer contains pre-recorded rainforest sounds and a library with all of the images; it interacts via a MIDI controller with (a) the pre-recorded sounds (through DSP processes programmed in MAX) and (b) the real time manipulation of the images (via 'Jitter'). Both computers display the SMPTE time from the master computer, to allow for an accurate performance throughout the entire piece.

Full automation of live-electronics processes, as explained in Garavaglia, [2] had to be used up to some extent herewith, mainly because of the extreme complexity of the performance. Full automation is partially used in the video interaction too, mostly in those passages in which both the pre-recorded sounds and the visual part need manipulation via the MIDI controller. It proved extremely difficult to manage the totality of these processes without some degree of automation. However, and given the partially improvised character of some sections, it was decided not to fully automatise the totality of the performance; instead, only those passages requiring a considerable amount of manipulation of the interactivity were automatically programmed.

Pitch and amplitude from the viola were the only parameters selected for the interaction with video. To read them, the first computer uses simultaneously two algorithms: the first performs pitch recognition

of the sounds of the viola, while the other measures their amplitude. The actual values of these parameters proved to be rather inconvenient for the mapping processes needed on the second computer in order to manipulate processes for the video sections of the piece. Hence, pitch values were multiplied by factor 10 while amplitude values were multiplied by factor 10000 before being sent to the second computer and mapped. These big figures allowed for a smooth interpolation of the diverse video parameters, without any noticeable rough changes in the video effects occurring. In this way, the viola's amplitude values were scaled from 500 (a number that proved to be rather efficient in avoiding unnecessary soft amplitude data) to a maximum of 10000. For rotation effects, these figures were mapped to 0.1 – 50.0 in the second computer for the Theta parameter (the rotation angle, measured in radians) of the 'jit.rota' object in 'Jitter'. The frequencies were mapped from 1300 (130Hz) and 50000 (5000 Hz) to 1.0 and 0.0 respectively for the zoom parameter (horizontal and vertical). Another type of interaction viola/video is the mapping and scaling of the amplitude values between 0.45 and 0.1 in order to change the temperature colour in 'Jitter'.

With regard to the live-electronics processes, they are divided in two sets: those in the master computer for the viola and those in the second computer for the pre-recorded sounds. The viola's live-electronics include the following DSP functions: ring modulation of two sources via two *Comb* filters, delays, reverb, convolution, granular synthesis, live-recorder/player and a 'spatialisator'. Sounds coming from the output of the ring modulator, the delay unit, the convolutor and the sample-player are sent in a circular or localised automatically programmed surround sound (4.1) using the 'spatialisator'. Another set of live-electronics was programmed for the second computer, which works mainly processing insect sounds from the rainforest. This second set includes: spectral extraction, comb filters, pitch shifting, chorus (for pitch or voices transformations) and granular synthesis. This second computer also includes spatialisation in 4.1 with circular movement (increasing or decreasing the speed between changes of loudspeaker during the performance at the will of the performer, with the intention of creating at certain moments an intense feeling of rotation) as well as localised distribution of sound.

2-VISUAL ASPECTS

As explained earlier, the principal technique utilised for the visual conception is that of the close-up, with several of the pictures shot using extreme zooming. The main type of image is that of the cortex of several and different trees, which were collected in the last ten years from many different types of vegetations, mostly Europe and the rainforest in South America. Other pictures stem from complete and isolated trees in nature, shot mostly in diverse regions of Europe.

The main intention of using close-up images of tree-cortices is to resemble surface areas, which seem to be borderless, as, due to the closeness of the shots, there is a complete absence of perspective. Hence, these surfaces become eternal territories in which they lose their attributes, transforming themselves from object to landscape. Through these images, 'Wooden Worlds' invites audiences to immerse themselves in a visual territory created by wooden textures mixed with different types of trees with diverse structures. Figure 1 shows two of the many close-up images used in 'Wooden Worlds'.

As all images used in the piece are included in some kind of interaction, they were all stored in a library in the respective MAX patch; most of them are selected randomly during the performance, with the exception of a few, which were pre-selected. At some moments, these surfaces emerge without any visual effect applied; at some other, however, effects such as, for example, colour and heat changes (programmed in 'Jitter') are introduced.

As an example, in the first six minutes, the performance begins in complete darkness and only with nightly sounds of insects, suggesting a typical new moon night in the rainforest; very gradually, the ambient light is increased by little grains populating the screen using the 'jit.noise' object, which creates a matrix full of random values in 'Jitter'. After a while these grains are transformed into the 'haptic image' of the tree cortex shown in Fig. 1 (left), creating an abstract landscape made of wood.

Besides these images, there is one video post-produced with the software 'After Effects' from two images: a wood cortex and a tree. It begins with an extremely detailed close-up of the cortex, slowly zooming out and thus, revealing the entire structure, which resembles a woman stretching the arms as if crucified. The video was produced to interact with the viola by modifying the playing speed via the pitch data from the viola, in order to create a tension through the extension of its duration. Controlling the speed with the viola frequencies produces herewith the effect of 'zooming-out' the image according to the music.

Other images were faded with the resulted rotated image with 'Jitter's jit.xfade' object to create a feedback continuously changed by the Theta parameter and by zooming (horizontally and vertically). This feedback effect creates a visual and chaotic multiplicity that is reinforced by the rotation parameter, which can be slow or fast, according to the music played by the viola. Another type of interaction viola/video is the mapping and scaling of the amplitude values between 0.45 and 0.1 in order to change the temperature colour in 'Jitter'.

3–SOUND AND MUSICAL ASPECTS

The sound and musical aspects of 'Wooden Worlds' include two main sources: pre-recorded concrete sounds and a live viola. For the latter, some sections were fully composed whilst other sections were left for improvisation. The pre-recorded sounds, based mainly on sounds produced by insects, were obtained in several nightly recordings in a tropical part in South America, in the town of Girardot (Colombia) and at the Amazon rainforest (Colombian side). As usual in tropical areas, there are plenty of insect sounds during the night, most of which are produced on, inside or close to wood. Temperatures in Girardot are normally around thirty degrees Celsius (average). The constant heat, together with a rather high degree of air humidity (in some parts of the Amazonas, air humidity is around 94%) are ideal climate conditions for a concert of insects' sounds and of other types of lives.

The viola (which is mostly made of wood) has a pivotal function across the entire piece as it interacts with other audiovisual materials of the performance: on the one hand, it interacts with the pre-recorded rainforest sounds and with sounds recorded live during the performance through typical DSP functions in real time programmed in MAX/MSP; on the other hand, it also interacts with the video part, as explained earlier. Sound interaction is included with the intention of either imitating the pre-recorded environmental sounds (mainly based on sounds made by insects) or to be combined with them. Therefore, the music composed for this type of interaction is that of short instrument actions (many of which are of undetermined pitch), that are supported mainly by sounds such as bow scratching the strings, harmonics or sounds obtained by knocking the instrument, to mention just a few. Most of these are of improvisatory nature, reacting live to the insect-sounds.

As the second type of interaction required a much more careful planning, the music for it was fully and carefully composed; here the viola must take control of different video parameters, some of which require a fixed duration and therefore, accuracy by playing. The parameters read from the viola for video–

interaction are pitch and amplitude. A clear example is the 'Elegy', which starts in the score of the piece at 00:12:15:00 (SMPTE time). The image here is the post-produced video introducing the image resembling the form of a crucified woman. The 'Elegy' was composed with this image in mind, with the video starting with a 'haptic image' (a close-up of a tree cortex), which moves slowly forward until the full image of the 'woman-tree' is displayed. This slow revelation was explained in section 2 above.

In the last section of the performance, the amplitude and pitch of the viola control other video parameters, namely a feedback of the original image combined with a zoom (via the viola's pitches), which is added to a rotation effect (controlled by the viola's amplitudes), creating a repetition and multiplication illusion of the image within the screen with a tense and chaotic visual result. During this section music, sound and image are improvised by both performers within a fixed and planned length.

With regard to the audio output of the piece, each computer is connected via Firewire to an audio interface, with a quadrophonic output each. This division allows for a clear and separated space for each of the sound sources (the pre-recorded natural sounds with their DSP processing and those from the viola, with its own DSP live-electronics). The octophonic settings are described in figure 2.

The piece was world premiered during the Kölner Musiknacht 2010 in Cologne, Germany (Kunst Station Sankt Peter, 25.9.10).

SOUNDWWWALKS

Bernhard Garnicig

Computer networks and cities both are social spaces that have emerged as material spaces where lives are lead and work gets done. While extensive studies on the Soundscape have been undertaken in the past, the sonic properties of network spaces have been left unconsidered and thought to be without sonic properties. The panel is an investigation towards an Acoustic Ecology of Networks and the WWW as interface and material for live performance.

Soundwwwalks are an emerging genre of live browser-based performances using <EMBED> improvisation, plugin sound-collage and multitab mixing, shamelessly blending the traditions of pro-surfing, Soundwalk composition and laptop music.

The performances take the audience on a sonic Detour through the World Wide Web. A Soundwwwalk considers the act of surfing the World Wide Web as form of sonic action.

The artists either perform their Soundwwwalks themselves on stage or transmit their notation, sometimes in real time, to a local interpreter operating the browser.

All performances follow the Soundwwwalk One-Line-Manifesto: "All sound sources must be played in a browser, must not be self-produced and must be publicly accessible."

The above description was part of the invitation I've sent to selected artists in the past, along with details about the date and other circumstances of the performance. So far Constant Dullaart, Joel Holmberg, Peter Moosgaard, Julian Palacz, Jamie Allen, Will Schrimshaw and Ceci Moss have performed the format at various events throughout Europe. [1]

Soundwwwalks were the beginning of an investigation towards the possibility of browser based sound performances. As an artist interested in internet art, sound collage, soundscape theory and improv performances, I started to understand that the World Wide Web has become the largest possible library of sonic artefacts and recordings, considering any sound and video file uploaded to the web any given day as material for sonic ideas and actions. I wanted to explore a way of working with this resource the same way I've used turntables for improv sound collage performances with Albert Allgaier in the past, or I've seen other artists using various objects, tools and instruments. But I wasn't interested in just sampling, ripping, downloading and then mashing with those materials as sound files in standard digital sound workstation environments, detached from their original ressource, as mere material outside the context of its source medium. I've found it to be much more interesting to work with the specific qualities, characteristics and phenomena related to the world wide web as a sound source, the network as intermediate space with quasi-acoustic properties and the desktop browser as the interface.

We developed different approaches to Soundwwwalk performances, especially because the invited artists often couldn't physically be at the site of the performance. While the performer would usually come on stage and perform the Soundwwwalk using a standard computer connected to the PA system and a projector, this can also be done through real time communication from anywhere else. A local performer will then execute instructions sent by the "composer" in real time. These come in the form of

hyperlinks and instructions regarding for example volume settings or particular timing requirements. What follows is an excerpt of a performance composed by Constant Dullaart, transmitted via text chat and interpreted by Bernhard Garnicnig live on stage at a Soundwalk performance at the interactive Media Art Laboratory Brussels in November 2010. The sound resources on the World Wide Web are ephemeral, much like the sounds exist in our habitat and environment. Briefly appearing signals and notes, their existence on the archive-in-motion is fluctuative for various reasons: YouTube takedowns enforced by copyright owners, users correcting their represented identities and editing their archives, servers failing, connections dropping, geographical access restrictions etc. Like a train passing and chatting couples passing by on the sidewalk, they appear and disappear. The Acoustic Ecology and the Soundscape Project have studied exactly the specific phenomena, histories and properties of sound found in our habitats. Yet so far, this type of research has not been expanded into the field that is now also a de-facto space where our lives are led, work gets done and social structures emerge: Although the spatial metaphors have been used for networks since a while (think about the volume of a MySpace, the length of a YouTube or the diameter of a CyWorld). The space of computer networks has been regarded as being a space without acoustic properties and sonic phenomena.

Since the 1970s, the World Soundscape Project used the practice of Soundwalk [3] and the term Soundscape [4] as analytical tools for their research of the sonic environment of the human habitat. These terms and methods since then have become independent and widely used artistic practices, Janet Cardiff & George Bures Miller Soundwalk projects [5] and Luc Ferraris Soundscape compositions ("Presque Rien ou le lever du Jour au Bord de la Mer" [6] being popular examples. Through a process of reverse engineering, the Soundwalk project is an initial effort towards establishing an analytical

framework for an Acoustic Ecology of Networks, starting with an artistic practice. The experiences and discussions this yields will contribute to a more elaborate jargon and finer differentiations to the field of network acoustics and the browser as potential platform for sonic expression.

OMNISCIENCE, SURVEILLANCE, DISCIPLINE: THE TRIUMPH OF THE VIRTUAL PANOPTICON

GREG GARVEY

Virtual worlds like Second Life and games privilege a single point-of-view and permit a change of identity thought to be desirable, liberating and fun. Users/players agree to Terms of Service (TOS) – a new feudal regime of ‘soft’ surveillance. Foucault’s analysis of Bentham’s Panopticon applies equally to typical Terms of Service. The mummified Jeremy Bentham, locked in perpetuity in a box, remains omnipresent and omniscient.

The eyes of the Lord are in every place. _Proverbs 15:3

POV

Artists, authors, filmmakers, game design and creators of virtual worlds have at their command a variety of devices to represent the point-of-view (POV) of the observer, character, playable character or avatar. In the long history of visual representation in western, non-western art along with the rise of modernism, contemporary arts but also in technical disciplines geometric perspective is but one of many different approaches. Although it actually distorts depictions of objects it retains the authority of truth. Technical drawing techniques such as isometric projections (or God’s Eye view) and even surrealism have explored alternative modes of representation of perspective.

The Privileged Gaze

Virtual worlds such as Second Life privilege a single point-of-view, i.e. the user. When logged into Second Life a user sees the virtual world from a default viewpoint, which is from slightly above and behind the user's avatar (the user's alter ego ‘in-world’). This point-of-view is as if the user were viewing his or her avatar using a (monocular) camera floating a few feet behind it. The user can also choose to see this virtual world from “inside the head” of one’s avatar as if seeing through the eye(s) of the avatar. In effect the user can easily shift from a first person, to third person (their avatar is seen as an other). Using the technique called Mouse Look users can even move that camera completely independent of his/her avatar and become an incorporeal all seeing-eye freed from the bondage of a body.

Scopophilia

This privileging of a single point-of-view matches Mulvey’s notion of scopophilia “a primordial desire for pleasure in seeing.” There is a sense of discovery, freedom and liberation as a result of un-tethering one’s point-of-view from the location of one’s avatar. In Second Life user’s avatars can also fly—long a dream of human kind. Flying affords a bird’s eye perspective on the virtual world. In addition teleportation permits avatars to instantly move (within technical limitations – laggy rezzing) from one location (another sim or simulation) on the grid in Second Life. For Second Life “newbies” this experience is liberating and even ecstatic.

We all live in a Gray Submarine

Jaron Lanier suggests that we tend to think of the brain as a computer and our point-of-view as seen through our eyes as a simple camera:

“The head is a spy submarine sent on a mission to perform a multitude of little experiments to learn more about its environment. These micro-experiments are often carried out by constant, subtle changes of the position of the head. By continually moving our head around in order to scan the scene, we simulate the effect of having far better eyes than we actually do, and in a far wider variety of placements. ...If you immobilize your head in a vise, you will see far less well. If you also stop the motion of your eyeballs, you will soon cease to see at all. The world seems to vanish into gray.”

Escape

Second Life also tempts the user with the lure of transformation and perfection. In Second Life the user's avatar is that body electric that triumphs over the human condition and promises a consumer's paradise of fulfillment. A promotional video on the Second Life web site answers the question of “What is Second Life?” with:

A place to be...

Be different

Be yourself

Free yourself

Free your Mind

Change your Mind

Our Second Selves

In her book *Life on the Screen* Sherry Turkle (1995) documents the hopes, fears, expectations of some of early denizens of the then emerging social phenomena of the Internet. She argues that these technologies bring “postmodernism down to earth,” “refuses modernist resolutions and requires an openness to multiple viewpoints.” In an article for *Wired* magazine she spoke of the virtual: “The anonymity of MUDs gives people the chance to express multiple and often unexplored aspects of the self, to play with their identity and to try out new ones.”

But easily changing point-of-view has ramifications. The practice of using multiple avatars requires a transformation of identity and personality. When a user 'enacts' the identity of a particular avatar, their 'real' personality is masked by the assumed personality. In real life such change can lead to psychological distress. In virtual worlds and games a change in identity or point-of-view is thought to be desirable, liberating and fun.

Two Heads are Better Than One

I have argued that virtual worlds like Second Life may induce a feeling of dissociation in users/players. Users may experience “derealization” (where objects appear unreal) and “depersonalization” (where people read avatar’s appear unreal or robotic) as defined by the Diagnostic and Statistical Manual of Mental Disorders (DSM-IV). If dissociation is experienced in real life it can be very debilitating and disruptive of normal life.

Reality Testing Is Intact

The clinical diagnosis of either of depersonalization or derealization indicates that “reality testing is intact” which applies to Second Life Residents and gamers. By changing gender, bodily features, proportions and clothing a Second Life resident “enacts” a different personality. With a different personality, especially in the case of gender comes a different perspective on the experience of being “in world.” It is possible residents of Second Life or gamers experience something akin to Dissociative Identity Disorder (DID) which according to the DMS refers to the “presence of two or more distinct identities or personality states” that “recurrently take control” of the user’s behavior. Could the user/player experience some form of cognitive dissonance if there is a struggle to integrate the different personality attributes and gender differences?

Various studies show that avatar selection can have a profound impact on behavior and self-perception both ‘in world’ and in the real life. VR researcher Nick Yee found that research subjects who adopted a taller avatar would out-negotiate those who selected shorter avatars. Commenting on Yee’s work, Jim Blascovich and Jeremy Bailenson conclude, “changes in avatar height changed their (study participants) behavior,” and that the “critical finding is that participants’ self-perceptions changed their behavior.”

Separation of Church and State

Extropia DaSilva considers the question how to manage the separation between one’s real self and a digital person:

“To what extent is a digital person separate from the person who is role-playing them? Many consider it impossible to create and sustain a personality that is substantially different from the RL persona. Others argue that current virtual reality is too crude to enable deep immersion into an alternate identity. As on-line worlds grow in sophistication, it should enable increasingly complex explorations of alternate identities.”

Liberation Theology

The prophets of the singularity see only the upside of multiple selves. With his proposal for the Law of Accelerating Returns Ray Kurzweil has prophesized the advent of the Singularity. We will be able to upload our minds to the cloud based on what Randal Koene terms “advancing substrate independent minds” (ASIM): “Mind uploading is the process of transfer, a process by which that which constitutes a specific mind is transferred from one substrate (e.g. the biological brain) to another (e.g. a silicon brain).” Will we retain our unique minds with different perspectives?

The Problem Concerning Technology

In the Winter 1993 issue of Whole Earth Review, Vinor Vinge raises many of the key issues surrounding the significance and impact of the Singularity:

“The notion of ego and self-awareness has been the bedrock of the hardheaded rationalism of the last few centuries.”

“What happens when pieces of ego can be copied and merged, when the size of a self-awareness can grow or shrink to fit the nature of the problems under consideration?”

Know Thy Selves

Extropia DaSilva provides a compelling vision of the coming future of multiple viewpoints:

“By the time mind uploading is generally available, perhaps people will have forgotten a time when a singular self was “normal.” They will be used to multiple viewpoints, their brains processing information coming not only from their local surroundings, but also from the remote sensors and cyberspaces they are simultaneously linked to.”

Exodus

In Exodus to the Virtual World, Edward Castronova sees “a hurricane coming” - the fun revolution, which he calls ‘practical virtual reality.’ Castronova points to basic economic theory of time allocation. All things being equal e.g. cost people “will pursue as long as possible activities that please them.” Castronova argues that the domain of synthetic worlds and the domain of the real world are in competition. “Time and attention are migrating from the real world into the virtual world. The exodus will strengthen, I believe. Improvements in technology will make virtual worlds into veritable dreamlands. They will be more fun, for more people. Simple economic theory predicts that in this competition, the real world is going to lose.”

Code is Law

While MMORPGs, virtual worlds and electronic games seek to provide a fun experience, all require that the users/players agree to Terms of Service (TOS). TERMS OF SERVICE according to Castronova fall into two categories: “One set of rules are proscriptions the designers hope players will follow more or less based on their own incentives. ...designers hope that a role-playing community will evolve that will enforce in-character behavior through its own norms.” The other class of rules “are ones that cannot be placed in code but about which the designers are dead serious..... The designers will execute any character that violates such rules, banning the associated account. E.g. harassment of other players on ethnic grounds.”

Lawrence Lessig famously wrote that “Code is law” and what is coded serves to ensure discipline and compliance. Castronova points out that “The cost of law enforcement, and of governance in general, is high now, higher than it has ever been in human history.” “To sustain good government, we either have to pay for people to do it, or figure out ...to automate it. ...The result of automated law in virtual worlds often feels like anarchy. You don’t ever see government—no police, no civil service workers, no mayors, only the occasional “game-master,” who has to come adjudicate problematic disputes. While gover-

nance is not apparent, governing is going on—in the code.” “We already have cameras that capture traffic violations and send tickets. Eventually the traffic light could speak directly to my car and simply prevent it from moving forward when the light is red.” Automated Real-world law is cheap! “Cheapness is a very powerful feature.”

The New Softcore Feudal Order

Rather than liberating TOS is a regime of ‘soft’ surveillance. Most include provisions that content created by users cannot infringe on the intellectual property rights of a third party; users agree to indemnify the owner of the virtual world from liability; all content created by users becomes the property of the virtual world owner and the owner retains the right to cancel a user’s account anytime for any reason. According to Greg Lastowka submission to the TOC is equivalent to a new feudal order: “Like peasants tilling fields around a medieval castle, users will lend their copyright labor and creativity in ways that will build the value of the virtual world platform, often paying for the privilege of doing so.” The end user licenses and terms of use regulate behavior.

Keeping Score

To enforce TOC and to make us feel part of something epic means tracking gamers and gameplay in order to provide feedback and recognition. This sense of the collective, being part of something larger is laudable, perhaps as McGonigal claims truly inspires awe, reverence and even humility. But we are reminded here of Blascovich and Bailenson’s rather innocuous sounding observation detailing the wonders of tracking systems: “The take-home message here is that people’s behaviors in virtual reality (Halo is indeed a virtual world-mine) are tracked, and therefore can be stored, analyzed, and used—for good, bad, or whatever the person collecting the information wants.”

The Ocean of Noise

On August 2, 2002 at the DARPATech 2002 Conference in Anaheim, California, Admiral John Poindexter (of the Iran-Contra scandal) rolled out the Total Information Awareness Program, sponsored by the Defense Advanced Research Projects Administration (DARPA). The vision for TIA was vast in scope and comprehensive and continues to this day under different through separate and parallel governmental, corporate and private initiatives.

“The most serious asymmetric threat facing the United States is terrorism, a threat characterized by collections of people loosely organized in shadowy networks that are difficult to identify and define and whose goals are the destruction of our way of life. The intelligence collection targets are thousands of people whose identities and whereabouts we do not always know. It is somewhat analogous to the anti-submarine warfare problem of finding submarines in an ocean of noise - we must find the terrorists in a world of noise, understand what they are planning, and develop options for preventing their attacks.”

In order for TIA to work effectively it must collect in its data mining operation the profiles of non-threats in order to distinguish the threats from the non-treats. Today we now know that the National Security Agency beginning in 2001, with the cooperation of the major domestic telecommunication providers intercepted Americans’ phone calls and Internet communications in violation of privacy safeguards established by Congress and the U.S. Constitution.

LOCATION BASED SERVICES

Today in the United States Apple and Google have launched their own data mining and tracking submersibles into the consumer info ocean of noise. With the spread of location-based advertising, marketing, or other applications both Apple and Google have been tracking the location of smart-phone and computer users. Apple surreptitiously logged the locations of cell phone towers and wifi hotspots adjacent iPhone and iPad users. CNET reported that while Google's Street View cars shot images for Google Earth, the vehicles also "collected the locations of millions of laptops, cell phones, and other Wi-Fi devices around the world."

Mr. Know it all

Google ex-CEO Eric Schmidt declared: "We know where you are. We know where you've been. We can more or less know what you're thinking about." In many ways Eric Schmidt echoes Psalm 139 of the Christian Bible:

LORD, when you look at me you know all about me.

You know when I sit down.

And you know when I get up.

You understand what I am thinking about? (even when you are) far away.

The Police

With the 1983 hit "Every Breath you Take" by the Police, Sting takes us from the sacred to the profanity of stalking. Like the omniscience of God, Sting is letting the object of his affection know that "I'll be watching you."

An ounce of prevention is worth a pound of cure

During an interview in December of 2009 Google Chairman Eric Schmidt served users of the internet notice: "If you have something that you don't want anyone to know maybe you shouldn't be doing it in the first place." This statement perfectly captures late eighteenth century English Philosopher Jeremy Bentham's idea of The Inspection Principle outlined in his proposal for the Panopticon – his "plan for a penitentiary inspection-house." The architecture is the physical realization of the Inspection Principle made possible by "the centrality of the inspector's situation, combined with the well-known and most effectual contrivances for seeing without being seen" made possible by a strategic placement of windows and partitions.

While it would be ideal to have each and every prisoners under "inspection" all the time Bentham acknowledges that is impossible (given limitations of staffing), so "the next thing to be wished for is, that, at every instant, seeing reason to believe as much, and not being able to satisfy himself to the contrary, he should conceive himself to be so." Fear of detection ensures prevention is the essence of Bentham's inspection principle. This operational principle of the Panopticon induces "a new mode of obtaining

power of mind over mind, in a quantity hitherto without example." In his analysis of Bentham's Panopticon Foucault describes the inspection principle this way "to induce in the inmate (user) a state of conscious and permanent visibility that assures the automatic functioning of power."

Here, there and everywhere

Now a trope of popular culture (the reality TV show Big Brother, Cheaters, MTV) the most visible manifestation of the virtual panopticon is ubiquity of security cameras. The London Evening Standard reported in an article entitled George Orwell, Big Brother is watching your house that as of 2007:

"Use of spy cameras in modern-day Britain is now a chilling mirror image of Orwell's fictional world, created in the post-war Forties in a fourth-floor flat overlooking Canonbury Square in Islington, North London. On the wall outside his former residence - flat number 27B - where Orwell lived until his death in 1950, an historical plaque commemorates the anti-authoritarian author. And within 200 yards of the flat, there are 32 CCTV cameras, scanning every move."

Dummy cameras provide the omnipresent threat of omniscience that ensures the internalization of compliance.

Smile We Are All On Candid Camera

Facebook adds over 100 million names each day, which rivals any database that the government might build. Google is not far behind. David Petrou an engineer at Google says that Google facial recognition software can identify the face of someone with a minimum of 17 online photos. With 50 or more Google can determine the person's name in most cases. Consumers willingly opt in this facial recognition software without concern. However, last year, a facial recognition system picked out more than 1,000 cases that resulted in State Police investigations, officials say. And some of those people are guilty of nothing more than looking like someone else.

It All in Your Head

The Brain Electrical Oscillations Signature test, or BEOS, was developed by Champadi Raman Mukundan, was used to win a criminal conviction. Using the scanning system, the accused murderer said nothing. But incriminating regions of the accused's brain where memories are stored lit up when the crime was recounted, ...The judge endorsed [the prosecutors's] assertion that the scans were proof of "experiential knowledge" of having committed the murder, rather than just having heard about it. The implication of such invasive techniques is also on uncertain ethical and legal ground.

Theory of the Future: The PANOPTICON

Invasive scanning techniques and brain implants were once the province of dystopian science fiction. Big Brother was a nightmare scenario of a fictional world that seems improbable in liberal open societies. The natural desire to see, to watch, to record, to remember is being harnessed through social media. The job of surveillance is being done by the consumer and it is fun. Users accept Terms of Service without reading and thereby agree to a regime of enforcement and compliance. Discipline is enforced because users know they might be watched and might suffer the ultimate penalty: denial of service.

The mummified Jeremy Bentham remains omnipresent at University College London. His frozen gaze suggests omniscience. He leaves us with this warning:

"...whether the liberal spirit and energy of a free citizen would not be exchanged for the mechanical discipline of a soldier, or the austerity of a monk? - and whether the result of this high-wrought contrivance might not be constructing a set of machines under the similitude of men?"

CURATORIAL CULTURES – CONSIDERING DYNAMIC CURATORIAL PRACTICE

Karen Gaskill

This paper will look at how responsive methods and approaches are called for when curating media-art-works, and how they shift the curatorial role to that of an active practitioner.

It will discuss exhibition strategies employed by the author, and how dynamic curatorial approaches can be integrated into mainstream curatorial roles, and how these can subsequently evolve thinking on the presentation and display of contemporary art.

“What”, I want to ask, “would it mean to think of art practice as the search for collaborators rather than as the search for an audience?” [1]

The practice of curating is live and temporal. It has shifted dramatically from its anonymous backstage origin within dusty museums to a role at the forefront of modern art, and is responsible for conjuring both a synergy and a dynamic that operates across a multitude of levels. Curation is a rapidly growing practice and discourse that is fundamentally shifting the ways in which we view and receive art.

This paper considers the curatorial role as that of an active practitioner, positioning it at a point of perspective. An excerpt from a recent PhD, this text presents a synopsis of a much longer articulation of the currency of the curatorial role in presenting and contextualising socially-engaged art practices.

Joan Gibbons, in her introductory narrative to the curatorial section of Hothaus Papers, reveals how the etymology of the word curate (as in 'curate' as a noun) goes back to the Latin word for care, 'cura', and through the religious art of the middle ages evolved into 'curatus', in reference to the care of the soul. [2] This is a particularly evocative description of the actions of the contemporary curator, as one that cares for our cultural products and their critical significance. Contemporary curators are summarised with a range of descriptive words such as caretaker, facilitator, mediator, catalyst, context provider, collaborator and negotiator. These have come to rise through the continuing prominence of the curator within exhibitions.

Traditionally the curatorial role was to collect, archive and preserve works of art, and was seen as separate from its variable display. Ramirez situates the curator as an internationally recognised expert of the artworld establishment, I quote: "in this elite context, curators have traditionally functioned as arbiters of taste and quality. The authority of this arbiter role derived from an absolute - ultimately ideological - set of criteria grounded in the restrictive parameters of the canon on western Modernism/Post Modernism." O'Neill, in Rugg and Sedgewick, [3] discusses the ascendancy of curatorial criticism since the 1960s, describing the critical shift away from the object of art, to a critique of the space of exhibition. More relevantly, he references the ascendancy of the curatorial gesture in the 1990s and how this 'began to establish curating as a potential nexus for discussion, critique and debate'. The rise of the curator can therefore be tracked through critical requirement. The role has adapted according to paradigm shifts, movements, cultural perspectives, and through the requirements of the work it chooses to curate.

The activity of the curator draws analogy to the Cabinets of Curiosity in sixteenth and seventeenth century Europe. The Cabinet of Curiosity, in its collection and display of often foreign and unseen objects, presented a tightly coordinated and rich tapestry of contexts and histories. Suggested as an early precursor to moving image culture (the notion of an audience roaming through a narrated space) the cabinet provided a specific audience with a metaphorical lens through which to view and understand alternative genealogies.

Such groupings of objects began the notion of storytelling and narrative within displays, and the provision of context and representation. Tony Bennett [4] writes of such museological cultures, 'the space of representation constituted in the relations between the disciplinary knowledges deployed within the exhibitionary complex thus permitted the construction of a temporally organised order of things and peoples'. Thus this aspect of the contemporary curator's role is not new, but through the lack of documentation of our curatorial history, many connections are still to be made.

The focus of the curatorial role has evolved from being that of a "behind-the-scenes aesthetic arbiter to a centralised position on a broader stage, with a creative, political and active part to play in the produc-

tion, mediation and dissemination of art itself.” [5] The practice of collection within museums and galleries still remains the same, with a continual need for the assimilation of art collections and their preservation and display. This ‘time storage’ as it has been labelled, is still massively important in cataloguing and preserving works. A perfect example is media art, where the necessity to archive digital and often ephemeral works is completely reliant on the survival of particular software and hardware. Therefore, to preserve the work, the associative technology must also be collected and conserved by the museum or gallery. The practice of archiving contemporary artworks has broadened relatively with the expansion of practices, and the responsibility of ensuring the future presentation of many works is thus massively reliant on the preservation of increasingly obsolete technical platforms.

Curatorial practice has come to embody one of the most dynamic forms of cultural agency available today. The challenges represented by this role and its ability to affect a series of interdependent areas inaccessible through other, more restricted, modes of cultural practices requires a fluid and multidimensional approach. [6] In the shift from the curator as master planner, Obrist [7] articulates how exhibitions have shifted from a historical approach of order and stability, to a place of flux and instability: the unpredictable. In thinking about the curator’s role at the helm of such uncertainty, it becomes much clearer how the position has evolved and its contemporary requirements shaped. This is also made clearer by the consideration of the types of work curated in contemporary exhibitions in relation to those being curated a century ago. The span of practices is growing rapidly, with new understandings and forms of hybrid practices being established all the time.

Therefore the position in which the contemporary curator sits is one of emergence and flux. I argue that the curator should be continually responsive to the type of work they are curating, if necessary changing their approach and looking sideways are what tactics of display best represent the work in question. The relationship between media art practices and traditional galleries is a recently formed one, with a history of littered with contextual and presentational misunderstandings. The main issue being that historically curation and its contextual knowledge has been developed and orientated around that of the art object. There has been no presentational challenge in displaying the works of painters and sculptors, obviously this is done with great knowledge and experience, but rather the challenge occurs when works come into being that are process-based as opposed to object-based.

As a contextualiser, the curator is often perceived as an “expert on art’s mediation by the sites of its display”; the area of curatorial expertise sits markedly between the “private sphere of the production of art, on the one hand, and the public sphere of consumption, on the other.” [8] However with this expertise comes a responsibility to the artist and their work in parallel to the audience. With experts drawing on their past knowledge of curation has meant that with the proliferation of more dynamic practices coming to the forefront of contemporary art, that this experience is not always relevant. It is difficult to curate work that is process-led with an approach that deals with art objects. So the question for many was how does one go about curating a process that involves audience members to make it manifest and in many cases realise the work. This issue was obvious in many of the early gallery shows, especially those which were not dedicated to media or participative practices entirely, or were solo shows, but were a selected mix of mediums. For me it felt that media works in many such shows were being curated on their physical presentation mediums as opposed to their relational attributes.

At this early point, the display monitor or computer was perceived as the work, it was a physical object, thus it was placed alongside other objects in the show accordingly. I use this as a broad example to iterate a point, and to reveal the difference between the curation of an object for display, where the curator takes into account the space required for viewing and exhibition sightlines, etc, to the curation of a

process. In this, where the physical presentation method is often purely a method of display, and where the essence of the work is revealed by the interaction of a user, viewer, participant, or otherwise, the curator needs to respond and work with the requirements of the piece, effectively curating the social, dialogical and reciprocal characteristics of a work.

The curator's relationship with site and space is ever evolving. Again I cite media arts as a prime example of how such practices have existed away from the formal agendas and white walls of the traditional gallery space. Such practices have always sought alternative spaces, primarily for the space requirements and that the significance of the gallery space is not entirely relevant to the dialogues they present. There have come to be more 'off-site' (non-gallery based) projects in recent years as exhibitions shift away from the white cube's signified emptiness [9] and critically acknowledge the role of site as part of the exhibition's context. I quote Brian O'Doherty [10] here, in order to contextualise Nick Kaye's description above, in his description of an ideal gallery, extracted from his book, *Inside the White Cube*. 'The ideal gallery subtracts from the artwork all cues that interfere with the fact that it is "art". The work is isolated from everything that would detract from its own evaluation of itself. This gives the space a presence possessed by other spaces where conventions are preserved through the repetition of a closed system of values'.

This merging of two critical directions; the white cube space of the object and the site-specific context of spatial works, has seen a new dialogue regarding the aesthetics of the relationship between artwork, place and audience develop. Exhibition spaces now exist 'off the map', and in the world, citing real life as their critical horizon and conceptualising the relationships and processes that occur within this context. (See fig.1).

I consider curation as being about establishing and contextualising a site of exchange: a space where artwork, site and audience converge. The 'exhibition space' exists where these conditions are met, and with Media Practices in particular focuses on the process of this convergence itself. This coming together of social, spatial and critical contexts generates a political space that exists within a wider cultural sphere.

There is no one set example of how media art practices function within a confined space, each performs differently, exerting different pressures on the conditional aspects that both determine and limit their relational capacities. Most works that function well in such spaces are often produced or commissioned to work within such parameters, and therefore are perhaps more site-specific in the traditional sense as they are intrinsically embedded within the site of production. However, such locations differ from their traditional predecessors in that the curatorial process also takes into account the relationship between site and artwork, and therefore is much more reliant on the audience to acknowledge and legitimise the connections made between the two.

This raw space provides a blank canvas for both the curator and artist that can be worked with accordingly to capture the characteristic of what the exhibition seeks overall to explore. Away from the agendas set by gallery spaces and the critical expectations of gallery audiences, alternative spaces reveal a space of potential, a space where anything can happen. This is very much a live space working with the conditions of subjectivity and presence, and dependent on an engagement across all elements. It is in this 'conditional' space that socially engaged and media practices projects sit, where contexts are formed and experience is lived. As an example, Allan Kaprow's *Happenings* are critically positioned by the artist, realised by the audience, influenced by the site, and politicised by the multiple perspectives

and opinions of the participants. This condition of immediacy where a conflux of ideas, perspectives, conditions and experience meet mimics in Kaprow's eyes the grit and texture of everyday life.

Such conditions of immediacy are also opened up through interactive media works and emphasised or furthered by the opportunities afforded by the chosen exhibition site. As suggested, alternative exhibition spaces remove the audience's 'authenticity', permitting them to function in a more natural role. These circumstances allow a public authoring of the exhibition itself, with the public's interaction with artwork and site both contextualising and realising the exhibition as a space of engagement. (See fig.2).

I want to touch on some examples of curatorial strategies that I have been implementing, and how these experiences have informed my knowledge as a curator. From 2005-2009 I directed and curated a small arts organisation called Interval. Based in Manchester, UK, it aimed to support artists using technology in their work through regular exhibition opportunities and networking events. Through Interval I attempted to approach the exhibitions I planned and curated from the perspective of curating the process of the selected artworks. This involved much more consideration of the appropriateness of space and site, and instead of thinking how the physical attributes of the show would be presented, I considered how the social space of each work would function, how they would work in relation to one another, and the potential for dialogue and exchange.

This curation of spaces for interaction and exchange very much shifted my perspective on the potential of exhibitions, and even working in gallery contexts with participative or socially-engaged artworks of all kinds, has reiterated the engagement that the curator needs to make with the 'exhibition space'.

So to conclude; 'Curator' is a term in the constant state of 'becoming' writes O'Neill, [11] 'as long as "curating in practice" is continuously willing a flexible "common discourse" into being'. It can therefore be said that curating is no longer about being somebody else, e.g. curator as negotiator or facilitator, it is about being a 'curator' as understood in discourse. The actions of curating mean different things to different curators, who again work in different contexts and situations, locations and sites. It is very much a cultural commentation role, experimental and discursive, necessarily responsive to socio-political and artistic shifts in a fluid culture. Our evolving curatorial dialogue seeks to embody movement and continuation in its descriptive qualities, and make visible and transparent the links and networks between meanings.

Curating is 'becoming discourse' where curators are willing themselves to be the key subject and producer of this discourse." I consider how Niklas Luhmann's writings on art as a social system, and in particular his articulation of a reflective practice, could be applied to curatorial practice. I suggest that this would compare the action of 'exhibition making' or curatorial practice as being the equivalent of making an artwork. Luhmann understands art as an autopoietic system that is self-referential and recursive. [12] I view curation as a similar thing. Curation enables the space of exhibition to open up new possibilities for dialogue and exchange, with these new perspectives feeding back into the way in which the exhibition is perceived and reflected upon. The 'artwork' or 'practice' of the curator is the exhibition and all of its associated processes, thus again coming back to Luhmann's notion of practice as not being solely concerned with agency but rather the work's understanding of itself and how this reveals possibility for an exhibition to raise questions about itself and its environment.

This becomes relevant when thinking about the broader social, cultural and political remit of curation and its practice. In its responsibility for the collaborative creation of context - that includes the artist/s; the artwork; the concept of the work and its representation; the facilitation of an exhibition's content;

orienting the body of work, and finally the space of engagement with an audience - curatorial practice is very much the actions of a bricoleur. In reflecting the messiness and complexity of everyday contexts and building a knowledge formulated by experiences and relationships, the curator is a responsive practitioner; a collaborator in art's social relations.

CYBISM AND DECODING THE LETTER: BUILDING AFRO-FUTURIST STYLED GAME LAYERS ON TOP OF THE WORLD

Nettrice Gaskins

The realm of street art is now a thriving knowledge culture that merges specialized forms of representation: alphabets, drawings, paintings, films/videos, choreographic notations based on programming languages, hardware, software, etc. This paper examines these guideposts that provide a basis for user-generated, performative, virtual and physical site-specific content that cross multiple disciplines and dimensions on emergent game platforms.

“Every new technology disrupts the previous rhythms of consciousness.” – Joseph Nechvatal [1]

To walk into the *Art in the Streets* exhibition at Geffen Contemporary in Los Angeles’ Little Tokyo neighborhood is to enter the realm of pure unadulterated street art. It is also to experience what is now a thriving knowledge culture that merges specialized forms of representation: alphabets, graffiti, films/videos, choreographic notations based on symbolic, linguistic and scientific formulations, programming languages, hardware (robotics, handheld devices), software, and so on. [2] This work emerged from a culture that has grown through the through the creation and application of forms that reflect the imaginings of urban futurism-inspired, hip-hop-styled texts that are rich in imagery and metaphor. These artists use the urban environment as their canvas that provides a basic framework to contextualize and evaluate street art production. This article expands upon art and media-related discourse of a kind of ontology, or metaphysics of presence to describe what takes place with the body, itself, not just the body that is embedded in public spaces but also how bodies are coded by society. A code is a rule for converting a piece of information (letter, word, phrase, or gesture) into another form or representation (one sign into another sign), not necessarily of the same type. This article aims to present a deeper, multi-layered translation of afro-futuristic, “wildstyle” graffiti and performance decoded through embodied new media, virtual 3D and augmented reality environments.

Modern graffiti and street art pioneers, many whose works are featured in *Art in the Streets* and elsewhere have provided artistic guideposts fueled by the increasing ubiquity of digital media that offer opportunities for its users to deviate from canonical practices of art and represent a complex syntheses of scientific and technological extensions of the body embedded in material and virtual spaces. RAMMEL-LZEE was an artist and theorist who lived for twenty years in a Tribeca studio loft he nicknamed the *Battle Station*. [Fig. 1] Museum curators transported his studio to the Geffen Contemporary for public viewing. *Battle Station* contains rarely seen video, sculpture, images and sound. It is part of what the artist

called “gothic futurism,” his urban, afro-futurist manifesto that embeds history, science (quantum physics), philosophy, science fiction, mathematics and technology. [3] The centerpiece of this production is “Gasholeer,” an upright, freestanding urban warrior figure covered in armor worn by RAMMELLZEE during live performances. “Gasholeer” represents this graffiti artist in his futuristic, urban realm – merging urban bricolage and detritus, mass media and street culture. The artist, embodied as an avatar, is surrounded by customized instruments and systems called “letter racers,” “monster models,” and “garbage gods” – objects designed to decode information into specialized forms of representation and invite visitors to become immersed in material and metaphysical space endlessly open to transformation and change. [4]

Modern graffiti comes from anywhere and takes whatever is needed from the environment. This practice relies on sign relations that consist of specialized art forms (tags, burners, etc.) that also describe aspects of presence, objects of reference and mental representations of spatial perception. RAMMELLZEE’s artworks consist of formulations on the juncture between black and Western sign systems (afro-futurism). [5] He realized that concepts are tools – technologies that could be crafted outside of the canon to make palpable specialized forms of knowledge that push the means of artistic production into the hands of outsider artists. His “panzerized” art forms, as cultural texts, are a basis for a symbolic and semiotic structure that relies on social interstices that mark or inscribe upon the body specific signs generated by society. RAMMELLZEE was part of a movement to create a space in which to untangle lines that cut across the past, present and future to establish an empirical framework. This framework is semiotic insofar as its structure depends on the process of perception and experience. Such development has largely been unexplored in scholarly discourse and is open for interrogation and debate. In her analysis Andrea Mubi Brighenti asserts that the common denominator that runs through graffiti, as an interstitial practice, is the materiality of the practice itself. [6] This article proposes a new form of analysis and interpretation based on the creation of new and alternative media content.

RAMMELLZEE appropriated and decoded letters of the Greek alphabet to create distinctly new art objects, transforming classic signature visual motifs into mechanical (letter racer) systems. Second Life (SL), an online, virtual 3D world, offers tools to re-appropriate and re-mix similar artistic constructions. As part of a Second Life art exhibition sponsored by the IBM Center for Social Media, I simulated portions of *Battle Station* and, through the use of in-world tools, constructed objects that were textured and assembled to simulate modern graffiti semiotics. [Fig. 2] Built into the SL software is a three-dimensional modeling tool based around simple geometric shapes that allows artists to build virtual objects. There is also a procedural scripting language, Linden Scripting Language, which can be used to add interactivity to objects. Users/avatars navigated this wildstyle-inspired, perceptually immersive 3D graffiti by virtually walking on, through, or around the objects, some of which were scripted to provide information such as links to external web sites and note cards with text that could be stored in an inventory. Extruding two-dimensional graffiti and incorporating interactive elements reveals new ways to decode specialized forms of representation that break set rules and establish new practices that extend viewer/user participation.

Imagine how much richer and multi-layered the experience of being in *Battle Station* could have been – exploring wildstyle graffiti and street art forms – using augmented reality (AR) tools on mobile devices. Visitors would have experienced a different *Art in the Streets* exhibition (at MOCA LA) if, while using their iPhones or Android smartphones to capture images, they had access to AR content that translated RAMMELLZEE’s complex vernacular. This multi-layered scenario is what makes virtual 3D and augmented reality environments promising for contemporary art. Graffiti artists, as part of a production process, encode, or take information from subcultural experiences, living in urban spaces and converting

this psychogeography into specialized symbols (graffiti tags, dance poses). Virtual 3D and AR tools can decode these symbols, as part of a generative and reverse artistic process, converting various symbols into information understandable by others. Emerging technologies create layers of information that explore the far-reaching implications of evolving epistemology and empiricism based on the body as a site for communication, represented in material and virtual domains and by highly stylized structures and code.

Along with the development of perceptually immersive, virtual 3D worlds like Second Life, augmented reality (AR) is becoming more accessible and new uses continue to emerge as tools for creating and customizing applications become easier to use. The layering of information over 3D space produces new ways to experience the world, as blended reality, that is fueling the broader migration of computing from the desktop to the mobile device, bringing with it opportunities for broader viewer/user dynamic engagement with social, digital, and mobile media. Contemporary artists are being encouraged to view their mobile phones, cameras, iPods and tablet computers as tools for production and display. These tools can be used to simulate real world issues and explore complex concepts in ways that are more 'user led' and increasingly participatory and collaborative. Graffiti psychogeography reveals creative practices that twist, interlock, converge and diverge media texts in a type of rhizomaniac, capitalistic and cultural schizophrenia. [7] Wildstyle, which in graffiti describes a complicated piece constructed with interlocking letters, also characterizes the development of experimental art forms, computer-controlled assemblages, and augmented, virtual reality tools. [8]

Evan Roth's *Graffiti Analysis* is one of several virtual graffiti applications that utilize motion and marker tracking, computer vision technology and programming to record and analyze graffiti art. The artists' gestures are captured, processed and used to generate projections and overlays that appear on the surfaces of structures in physical spaces. [Fig. 3] Here, complex graffiti vernacular is represented in the language of information analysis, offering a system for greater understanding of a highly coded form of creative expression. [9] This development is further explicated by "cybism," a term that describes a "system dynamics with a hybrid blending (cybridization) of the computational supplied virtual with the analog." [10] As defined and coined by artist-theorist Joseph Nechvatal, cybism is a "new sensibility emerging in art respecting the integration of certain aspects of science, technology and consciousness – a consciousness struggling to attend to the prevailing current spirit of our age." [11] Nechvatal claims that cybism can be used to characterize our understanding of where cultural space is developing today. His notion blends the virtual and augmented with the analog to be used as a theoretical basis for newly imagined realities that merge in cybism.

This development merely scratches the surface of what is possible with new and alternative media technologies and further expands the scope of experimental critical media theory. Performance and motion capture, blended reality, and wildstyle abstraction reflects an evolving knowledge culture (graffiti, breakdancing, b-boying) that employs verbal, written, artistic, or performative representations of media in the body. Doze Green's paintings translate complex metaphysical concepts that resonate with urban futurism, such as the "possible manipulation of energy and matter to create a timeless space." [12] Bodies in motion effortlessly translate into symbolic, linguistic and spatial formulations. The performative language of graffiti – windup, tilt, float and freeze – generates dance poses and letters that are manipulated into recognizable forms. Graffiti is represented in the language of information analysis. "King of Style" Kase 2 enabled a whole generation of artists to break from traditional forms into a more modern complex lettering system based on computer technology. Artists and writers who copied and amended each other's designs devised a variety of methods. Freelance hacker Josh Nimoy designed a Kase 2-inspired brush style for Graffiti Research Lab's L.A.S.E.R. tag system.

Futura (formerly Futura 2000) was one of the first graffiti artists to translate the wildstyle aesthetic into other art forms as a synthetic purification and intensification of certain ideas and visual elements. In the nineties he gravitated to the World Wide Web to create an archive of original work and to communicate with users on multi-dimensional levels. Cultural catalysts and practitioners have charted the development of modern graffiti, from the subway system to new media systems. Futura writes, “To keep in step with the fast pace of communication and information sharing ... what had started out as playing in subway tunnels had progressed into midnight forays deep in the interiors of the system.” [13] Futura is describing the emergence of a “cybistic zeitgeist” that seeks to capture specific aspects of graffiti and street art in order to formulate new inscriptions and representations (layers) that can be built upon and worked with to expand creative expression and innovation, through the use of game and mobile technologies. The acquisition of this work is epistemically advantageous and can facilitate a broader understanding that extends to electronic art and emerging, experimental game technologies.

The Modern Museum of Art (MoMA) interviewed artist Lee Quinones who discusses the development of the graffiti artist’s signature (tag). [14] Quinones demonstrates on paper RAMMELLZEE’s complex process of abstracting letterforms and transforming them into systems that have influenced contemporary graffiti artists such as SEEN, TWIST, AMAZE, KETONE, JONONE and KATSU who have had their tags captured and saved as Graffiti Markup Language (GML) files, a digital standard used by *Graffiti Analysis* and other applications. *Tagged in Motion* synchronizes gestural movement with an augmented layer of laser graffiti tags. This augmented reality performance combines graffiti art and its virtual 3D representation. Equipped with a handheld augmented reality tool, artist DAIM sprays graffiti into empty space. Three motion-capture cameras record his position and the movements he executes with a virtual spray can. The resulting data is shown to him in real time through a pair of video glasses – as free-floating three-dimensional graffiti in space. [15] *TagDis* is an iPhone app that lets its users design graffiti and street art using Augmented Reality technology. [16] Players see their tags – and those of other players – in the real world. This development will continue to converge on emergent game platforms, some of which will continue to expand the potentiality of new media to solve real problems, map specialized art forms and bring together disparate communities that share an interest in these systems, whether found in code, museums, or on the street.

A case study for real world problem solving is the *Graffiti Grapher* application created by Rensselaer Polytechnic Institute (RPI). [17] Ethno-mathematician Ron Eglash and his computing team developed this web-based applet that uses graffiti artifacts and artistic practices as a means to engage learners in STEM (science, technology, engineering and math) concepts. *Culturally Situated Game-Based Learning* is an innovative planning project (launching in fall 2011) that merges successful and proven models of game-based learning with culturally situated digital media strategies to help bridge the gap in STEM learning among under-represented minority students and non-traditional learners. This will be achieved using *Graffiti Grapher* and other existing “culturally situated design tools” and applying them to existing virtual 3D and augmented reality toolkits created at the Georgia Institute of Technology’s Experimental Game Lab and by the Gvu Center’s Augmented Environments Lab (AEL). [18]

Experimental, emergent game-related technologies are the next layer of development and require careful investigation. This presentation reveals resonances of a thriving knowledge culture on emerging, experimental game technologies. It is a multi-faceted attempt to position this production in a broader cultural, historical and theoretical purviews of which audiences that are familiar with certain aspects are already cognizant. This move ultimately aspires to inscribe, or even imagine a potential place for urban, street art in the next phase of conceptual and technological innovation to inform a more meaningful

critical theory of epistemic culture that is responsive to empiricism and constituted by models of recognition and reflection.

BRINGING THE IMAGINARY BACK INTO PLAY

ALISON GAZZARD

The term 'ludic' can be linked to many aspects of play and games, but what does it mean to be playful? Using examples of various augmented reality game, this paper will examine the role of mimicry in play as a way of understanding the ubiquity of ludic interfaces in light of our real world explorations. It will also highlight the importance of exploration and discovery in how we perceive, perform and create spaces of playful interaction.

"If there is one significant contribution of digital technology to gaming, it is to have reconciled competition and make-believe..." (Ryan 2007)

The term 'ludic' can be linked to many aspects of play and games, but what does it mean to be playful and where and how does this play occur? It can be seen that instead of being fixed experiences, digital games instead act as platforms for various experiences. Mobile phones, in particular the rise of what are commonly described as 'smartphones', have allowed for an increase in 'app' culture. Games are available for free through the various app stores (such as the Android market place or Apple's 'App Store') or for reasonably small amounts of money. Although handheld gaming has been around for decades, most notably through the various incarnations of Nintendo's Gameboy system, the ease of downloads and increasing integration of games with mobile phone devices has allowed these games to reach greater audiences without the need for separate, dedicated hardware.

In terms of hardware, smartphones also contain other inbuilt systems such as gps receivers, digital compasses, gyrometers, cameras, data connections and so on, once again allowing the game experience to change in different ways. Writing about non-digital games in the 1950s Roger Caillois distinguishes between 'ludus' or what is often seen as purely ruled play and the act of exploration, discovery and the pleasure of 'paidia', the notion of "...wild, free-from improvisational play..." It is not to say that these categories remain as fixed, binary oppositions, but instead work as a sliding scale of playfulness across a range of game playing experiences. Alongside his categories of "ludus" and "paidia", Caillois (1958) distinguishes between "agon, alea, mimicry and ilinx", equating to competition, chance, make-believe and vertigo. Although it is possible to understand these categories in light of non-digital games, what happens when real and the virtual start to combine, as in the case of augmented reality gaming? The growth and development of augmented reality (AR) applications through both videogames and smartphones now allows for the player's real world landscape, whether that be indoors or outdoors, to be transformed at the touch of a button. AR technology combines the world viewed through the camera screen with a layer of fictional objects allowing this technology to enhance and create different acts of play.

As it stands, augmented reality currently offers two main modes of delivery, either through markers, or through using location. The game *ARBasketball* released on the iPhone is one such example of using a marker-based system. Although it is played on a portable phone device, the user is required to print out a marker from the creators website before they can start playing. The marker then transforms into a basketball hoop once positioned in front of the camera (with the *ARBasketball* application running). Here, both the paper marker and the resultant image on screen link together as props to create the fictional and imaginary world, the notion of "mimicry" as discussed by Caillois. Wherever the real life

marker based prop is moved to, so to is the fictional basketball hoop, bridging the gap between the two realities and creating a portable game experience.

As Kendall Walton (1990) notes, "Props are generators of fictional truths, things which, by virtue of their nature or existence, make propositions fictional". In discussing the scenario of children playing a game of make-believe where tree stumps in the forest turn into imaginary bears, Walton discusses the underlying agreement of all players that stumps are part of the imaginary fictional world. In this instance we can see the applications of augmented reality acting as a toolbox of props that can be used to create different play experiences. Instead of having to imagine the world of stumps as bears, it is now possible for the technology to turn this into a displayed (virtual) reality. Although props can be present in other digital games, augmented reality is allowing for a layering of a prop, transforming a real world space into an extended playground of possibilities. The recently released *Ball Invasion* iPad2 game is an example of this. The game relies on the difference in patterns within the real world space to layer an augmented gamespace over the top. In calibrating the application, players are then able to play various shooting games, bouncing virtual balls at different targets within different depth layers. The balls also interact with the surrounding real world landscape, animated to seemingly bounce off the walls of the real world space when the virtual targets are not hit. The world created is pure mimicry, an imaginary world created through the combination of technologies. In doing so this standard game of chance is combined with a space of imagination, a combination of categories seen to be 'forbidden' by Caillois, stating "simulation and chance are no more susceptible to mixing" (p. 73). This is true of any digital game, where the simulation is created by the technology as a platform for a different kind of playful experience as once imagined by Caillois. The same can be said of 'ilinx' or vertigo, and its forbidden relationship with competition and rules. The portable nature of the mobile phone combined with the locative aspects of augmented reality can see player's moving through periods of vertigo, spinning round playfully trying to find new fictional spaces to explore.

Applications such as *Layar* (an augmented reality browser) allow for the creation of these playful experiences, often recreating our childhood memories of fictional worlds, imaginary places and ideas surrounding new possibilities of play. Instead of relying on markers, *Layar* allows different augmented reality games to be played through using location-based data and the digital compass for direction. An example of this is the *Layar* titled *ScavengAR Hunt*. Much the same as a normal treasure hunt, players have to find the objects displayed on screen as they explore the area around them. Objects are marked such as octopuses and swords, creating a world full of props for our imaginations. These props can be used as the starting point for new play experiences as the portable playground of the mobile screen extends the world around them. Although the props may remain the same, the location of play changes, creating new meanings and experiences. The game functions in much the same way as the real world experience but can be updated with every re-load of the application refreshing what objects are shown and where they may be found. The turbulence or 'ilinx' combined with the mimicry of play return to these games with these various layers. Player's can now stand up, spin around and furiously attempt to shot the virtual spaceships appearing on screen, found all around the player. However, this play can be competitive, both between players and by individual players competing with themselves, allowing for the categories of ilinx and competitive ruled play to emerge through the possibilities of the platform.

This is the key distinction of playful digital media; it is now possible for players to use these applications as platforms. Players can create their own play experiences through extended layers of their own imaginary and much of this play comes through the initial exploration of each application's use. Augmented reality, in particular, allows for an exploration of both the real and virtual world spaces to see what they can offer on each play. AR creates the possibility of two layers of fiction intertwined with the real world,

that of the virtual depicted fiction and the extra fiction created by the player's own imagination. Together these allow for various types of play experiences to evolve out of the props on offer within the interface and the simplistic nature of many of their designs allow for different types of game and play scenario to emerge. As has been briefly outlined above, the platform(s) of play are now accessed through the mobile interface, the "space of possibility" (Salen and Zimmerman 2004) continues to be opened up to players as they seek to bring the imaginary back into play.

LOCATING THE LOCAL/MAPPING THE NETWORK

ALISON GAZZARD

The project seeks to understand the changing landscape of local areas through location-based applications. The changing nature of the map is captured at different points in time as a way of analysing the ephemeral landscape of data depicting the opinions, locations and imagery left as digital memories or tokens by those within the area. The narrative of place is re-examined in light of this user-generated content.

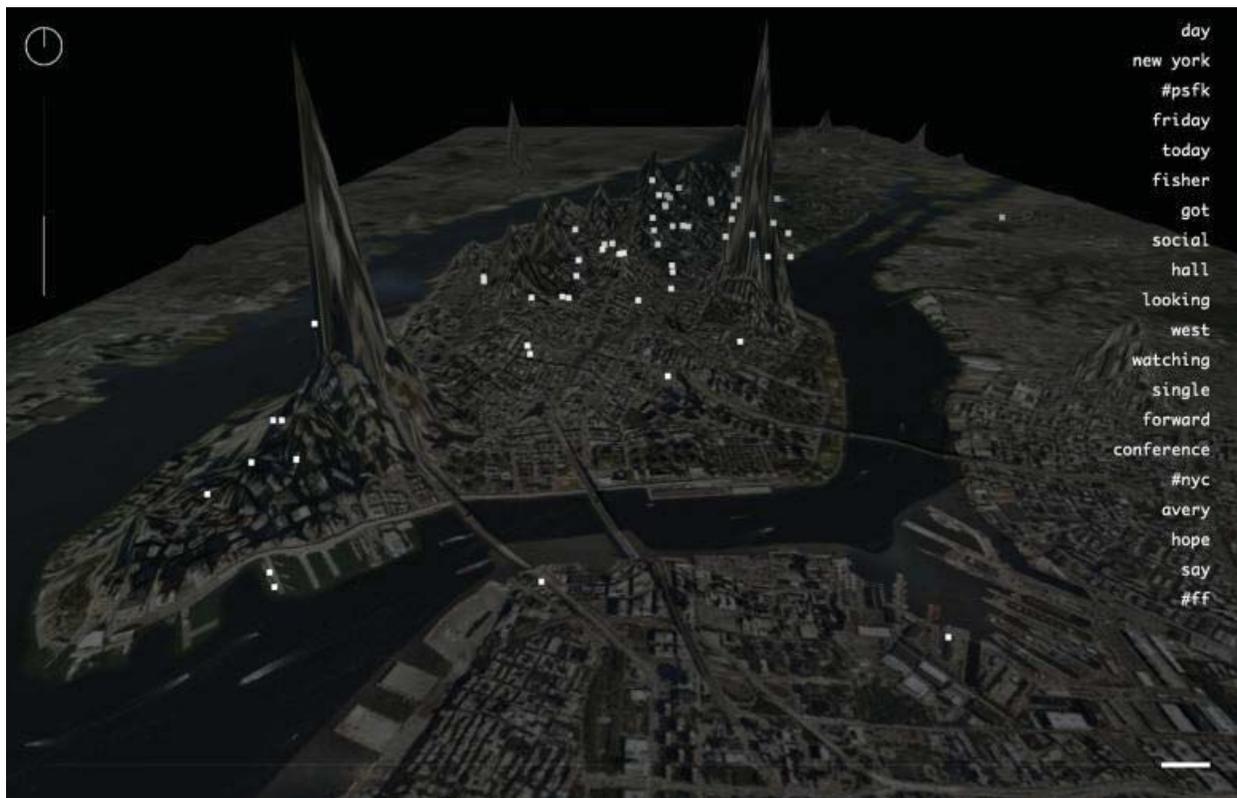

Figure 1. Invisible Cities data captured 13th May 2011. Copyright 2010-11 Christian Marc Schmidt & Liangjie Xia.

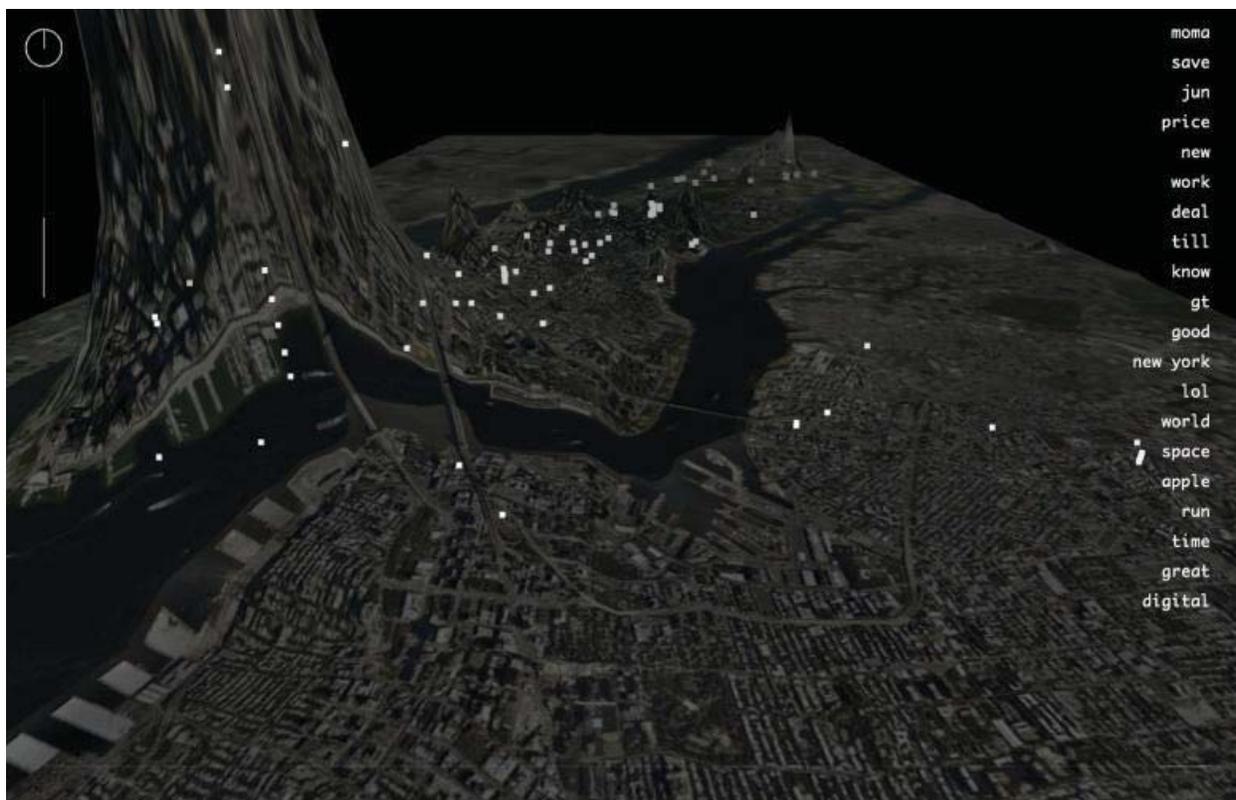

Figure 2. Invisible Cities data captured 1st June 2011. Copyright 2010-11 Christian Marc Schmidt & Liangjie Xia.

"Cities are comprised of complex social networks. In addition to the physical architecture these networks define our experience of the urban environment." _Schmidt & Xia 2011

As many have written, to walk the streets of the city or town is now to walk the streets whilst being connected. The ubiquity of the mobile phone, and the increasing use of smartphones in particular are seemingly 'always on', connecting to data networks often combined with GPS and allowing for locations to be tracked and defined. But what happens to this location data and how are users shaping various landscapes through the use of geo-located information such as tweets, check-ins and embedded photography?

Eric Gordon writes of "network locality" defined as "the experience of interacting with located data within the perceived infinity of global access" (Gordon 2009, p. 22). It is through these networks that we, as users, are frequently able to locate ourselves, our actions, our places and our thoughts through a variety of media applications and technologies. The smartphone, alongside the ease and open access nature of digital mapping systems such as Google Maps and Open Street Maps, has seen an increase in how and when people now choose to locate their activities. Photographs can be geo-located, capturing places frozen in time. We can check-in to virtual equivalents of shops, work buildings, or our own homes with applications such as *FourSquare* and *Gowalla*. Each of these instances is only possible through an

underlying network of global connections. However, it is through this 'global access' that we are now also changing the mapped narrative of many local areas.

The map is more than a means of seeking directions, but allows for a visualisation of data in various formats. Each time people log in to *Foursquare*, *Gowalla* or *Facebook Places* they are locating themselves on a map, they are providing a representation as to the area they are in. Although users cannot see the extended map of data whilst using the application, various mash-ups have been created integrating different APIs with Google Maps as a way of visualising each check-in location in relation to one another. This project will focus on mapped data collected from areas local to the GPS co-ordinates of each data collection. *FourSquare* places, ephemeral geo-located tweets and geotagged photographs will be visualised against a background of a local map. Each area will be defined in terms of a community or town, and will be viewed as an isolated snapshot, depicted as a miniature mapped landscape in amongst the surrounding area.

The project seeks to understand the changing landscape of each local area by analysing what John Pickles (2004) defines as "socio-spatial identities" that he sees to be the basis of many contemporary maps as "digital mapping has begun to influence many more domains of social life" (p. 10). Whereas many location-based applications seek to define the user's position in amongst a global network, this project examines the changing narratives of the local area through numerous check-ins, tweets and images. The changing nature of the map is captured at different points in time as a way of analysing the ephemeral landscape of data depicting the opinions, locations and imagery left as digital memories or tokens by those within the area. The narrative of place takes precedence over the identity of the user as places and spaces are re-examined in light of this user-generated content. It is through looking at these maps that we can start to see how local areas are being shaped by this data.

One such project providing a representation of geo-located Twitter feeds and Twitter trending topics is Christian Marc Schmidt and Liangjie Xia's (2010) project titled *Invisible Cities*[1]. As stated on their website, "Invisible Cities maps information from one realm – online social networks – to another: an immersive, three-dimensional space. In doing so, the piece creates a parallel experience to the physical urban environment" (Schmidt 2010). On loading *Invisible Cities*, the user is presented with a three-dimensional mapping of New York. The underlying map is familiar to those having ever viewed the data from Google Maps or Google Earth, and landmarks such as the Hudson River are viewable as well as the various sections of the city including lower Manhattan and Central Park. Each real-time piece of geo-located data from *Twitter* and *Flickr* changes how the city is represented and viewed. Imaginary spiked hills are constructed, distorting the mapped view of the city, creating a new imaginary space of digital data. As the density of location data changes, so do areas around the city. One day the city may be viewed as in Figure 1, the next day the city is shaped as in Figure 2. This view of the city is now re-arranged through the new layer of location information. As de Souza e Silva states, the city has become a "hybrid space", a "mobile space, created by the constant movement of users who carry portable devices continuously connected to the Internet and to other users" (de Souza e Silva 2006, p. 263). As de Souza e Silva notes, hybrid spaces are not purely augmented spaces, and this is especially true of *Invisible Cities*. There are various layers and combinations of actions taking place in order to create the piece. There is the layer of data provided by users geo-locating the information in the New York area. There is the two-dimensional mapped layer showing areas familiar to both locals and those having viewed New York on various maps and satellite views. Then there is the layer of the map and the data combined to form the resultant viewpoint, manipulating the local view in real time to provide yet another perspective. An augmentation would see these spaces as separate, leaving the map in tact and adding an extra layer of data on top. However, in this instance the map becomes a hybrid of user and place shaping the city and creating

rhythms of movement over a period of time. The user cannot see these distortions as they themselves walk the city streets, but it is through their actions that others can view the landscape in a different way. Here the narrative of the city exists in peaks and flows through the changing visualisation. As Christian Marc Schmidt and Liangjie Xia (2011) note in discussing *Invisible Cities*, the work depicts a "new kind of geography in which the urban landscape is reframed through narrative (a sequence of events in space and time)." Maps are no longer static and fixed. The growing trend of geo-location constantly seeks to change the map creating temporal-spatial narratives that change depending on the moment they are viewed. It is these narratives of place that I wish to explore further through mash-ups such as *Fourwhere*.

In examining my local area I can access *Foursquare* check-ins of nearby shops, takeaways and conveniences as well as view the tweets of strangers around me. These views differ to my own relationship with the area, the shops that I visit frequently in person, the people I may or may not see. A five minute walk from my home there is a parade of shops. They exist in a line, one next to the other. However, the view on *Fourwhere* is quite different. *Fourwhere* is a mash-up of *Foursquare* data plotted on Google Maps. You can search any area and find foursquare locations that are mapped around that immediate area. As with any Google Map you can zoom in and out to make the search area broad or narrow, but the application generally works more effectively on a local level. When zooming into the street by street level of my local area I am able to locate the shops. Not every shop is added on Foursquare therefore only shows a snapshot of what local people and businesses decide are relevant to the area. Much like *Invisible Cities*, *Fourwhere* provides a layer into the geo-located world of users in the local vicinity. The density of shops in the local area have not been replicated within *Foursquare*. Instead, only a handful of shops are displayed when trying to check-in on the application. Most notable are the supermarkets and takeaways that appear, potentially hoping for users to get 'specials' (such as discounts for the mayor, etc). Smaller stores such as the optometrists and travel agent are not found as check-ins (as of the 19th May 2011). This may be due to the fact that these two stores take up the same amount of street space as one full sized store, and/or are less frequented by users of the application.

This is where the user becomes noticeable within the mapping of data. It is only through companies or individuals adding themselves to the *Foursquare* database that they then appear as check-ins. If local users/businesses do not feel the need to create these places they are then left off the mapped database. In terms of viewing the spatiality of the *Fourwhere* map, these places no longer exist within the layer of my locality. Certain places take preference within this new map of my area. The map can be added to and grow over time as more check-ins are established but it acts as a separate representation, a local area frequented by those connecting online. This layer of check-ins can change the identity of the area when viewed against other representations of the local area. Place names can be misspelt, such as one local bakery being named a 'balery' (as shown in Figure 3). This adds a layer of almost fiction to the area. The misspelling changes the place into something new that only exists within the layer of the geo-located machine data. I can access the 'balery' online but in real life it will be known by its correct name. It is through the creation of the user's own places that there are multiple 'homes' in my local area. Places are created and called 'home', yet this is a place name that only means something to the creator. They are not my home (although I can virtually visit and check-in to it) and one of the homes is not the same as the other home created by another user. The geo-located network allows for multiple identities and in doing so the layer also allows for multiple entries creating numerous overlappings of different (or sometimes even the same) real life places. It is through this ability to create places that we can also see the opposite trend occurring in local areas. Although places have networked access and data streams, it does not mean that it will be inundated with Foursquare check-ins and geo-located twitter feeds.

As de Souza e Silva (2006) writes, it is "not possible to define a worldwide cell phone culture, because cell phone use differs substantially from place to place depending on cultural and socioeconomic factors." Therefore, some places end up existing free from this layer of digital locative urban commentary. On a recent trip to the Sierra Nevada mountains in Spain I found limited foursquare check-ins. I stayed in the town of Bérchules with access to a free wi-fi network in the apartment and generally good access to a mobile phone data connection. However, the people of Bérchules (even though they are connected, and some have smartphone access) choose not to check-in to their daily activities. Location is based around adding hotels and bars that tourists may want to visit on their travels. Location is also very much often limited to whole places rather than separating those places into various shops, cafes, etc. When logging in to *Foursquare*, the town itself was a place and existed as one mapped area (until I decided to add the place I was staying in). In many ways the layer of check-ins within this vicinity switches to a purely tourist view of the area and everyday usage fades away. Yi Fu Tuan's notion of "place" becomes "space" as the familiarity of these locations is not always known in detail to passers-by. Tuan notes that "when space feels thoroughly familiar to us, it has become place" (1977 p. 73). Therefore, tourists may not frequent the local shops on a daily basis, and the locals that do, do not see the need to leave a digital trace of their everyday occurrences. People passing through may often leave their own mark such as the restaurants or hotels they have been to in amongst the places they visit, but these now exist as mementos of an experience, rather than a constantly viewed place linked to everyday life within that space. There is no need for every building to be 'placed' and instead the whole village becomes placed in amongst the wider area, not succumbing to the finer detail of dozens of check-ins within the local vicinity.

Unlike the hustle and bustle of a large city such as New York, this absence of geo-located data reveals a slower pace of life, as the rhythms of the city are found within the quotidian streets and not through mash-ups of location-based data. The layer of location within the local area does not change as frequently, producing a different type of spatial-temporal narrative played out in a new way. As this project has shown, geo-location is more than locating objects, tweets and places. It is a way of creating various layers of information about an area. Mash-ups, maps and applications all reveal piece of a place, sometimes joining to show the ever-changing nature of how that place is experienced. Yet for those only able to experience the digitally mapped representation, this data offers a window into a partial place, revealed only to/by those choosing to leave their mark and create another layer to be viewed by others accessing the network.

MATERIAL MATTERS: MACHINE AGENCY AND PERFORMATIVITY

Petra Gemeinboeck & Rob Saunders

This paper explores new forms of entanglement between human and nonhuman agents. In considering the performative potential of intelligent machine agents, we are interested in shifting the focus from representational issues to questions of agency and materiality. The investigation revolves around the authors' robotic installation "Zwischenräume".

Fig.1. Zwischenräume, robotic installation, robococo (Petra Gemeinboeck & Rob Saunders) © robococo

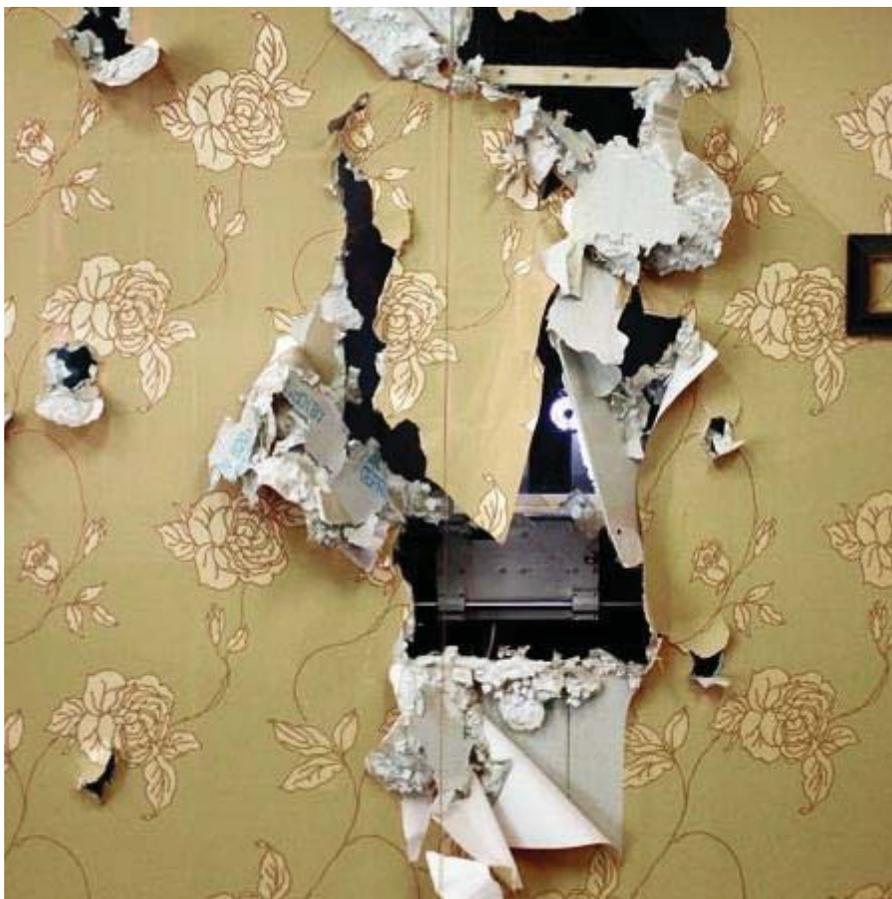

Fig. 2. Zwischenräume, robococo: two weeks into the exhibition © robococo

In early Artificial Intelligence approaches, robots sensed their environment, built complete internal models using the sensed data, constructed plans based on those models, and acted to execute their plans. Even though they acted in the world, the world they ‘conceived’ and acted upon was a separate, disembodied reality. Contemporary approaches, in contrast, aim for intelligence that emerges from interacting with the world, thus emphasizing situatedness and embodiment (Brooks 1991, Harvey 2000). The agencies performed by these ‘intelligent’ machines evolve based on the dynamics of their material context. It is only when robotic agents are coupled with an environment, that, according to Beers, their potential to act is realized through the agent’s behaviour in that environment (1995). This is a starting point for considering ecologies that entangle human and nonhuman agents through embodied experience of a shared environment. From a posthuman point of view, embodiment is always contextual and specific; agency is materially enacted and distributed across bodies, rather than located within (see Hayles 1999, Barad 2003, Bennett 2010). Without disregarding their differences, both human and nonhuman agents adapt and know not by observing from the outside, but because they act as part of the world (Barad 2003).

This paper explores new forms of entanglement between agents, human and nonhuman, and probes into their performative potential. Our investigation seeks to set up a conversation between disciplines by looking at the potential of machine agency through the lens of materialist performativity. The notion of the performative here refers to the productive and, at the same time, destabilizing enactment of agency as agents engage with their environment. In considering the performative potential of intelligent

machine agents, we are interested in shifting the focus from representational issues to questions of agency and materiality. First, we will discuss embodiment and agency as they are applied in the Dynamical Systems approach to robotics and conceptualized in feminist materialism. The investigation of how, together, these two can open up a third lens through which to look at the performative potential of machine agency will revolve around the authors' interdisciplinary robotic practice and their work *Zwischenräume*: a machine-augmented performance environment, which embeds a group of autonomous robots into the architectural fabric of our environment.

The Dynamical Systems view of agency is based on the observation that “animals are endowed with nervous systems whose dynamics are such that, when coupled with the dynamics of their bodies and environments, these animals can engage in the patterns of behavior necessary for their survival” (Beer & Gallagher 1992). Artificial Intelligence inspired by this view degrades intelligence “in favour of the concept of adaptive behaviour” (Harvey 2000). The lived phenomenal experience of knowing-how outplays the information processing of knowing-that. “Treating an agent —creature, human or robot —as a dynamical system coupled with its environment through sensors and motors, inputs and outputs, leads to a metaphor of agents being perturbed in their dynamics through this coupling”. This contrasts the traditional AI approach, according to which agents are “computing appropriate outputs from their inputs” (Harvey 2000). The metaphor resonates with Varela's co-evolution between a system and its environment or another system: both evolve through mutual perturbations, setting off a trajectory of mutual adaptations to compensate for the external perturbances. The two structurally coupled systems “have an interlocked history of structural transformations, selecting each other's trajectories” (Varela, 1979).

As a general formalism the Dynamical Systems' perspective can be applied to computational systems as well as non-cognitive and non-computational physical systems. Its potential to straddle the Cartesian boundaries between mind, body, and the environment (Clark 1998) opens up a path into thinking across human and nonhuman agential capacities.

Looked at from a posthumanist point of view, embodiment “always is contextual, enmeshed within the specifics of place, time, physiology and culture, which together compose enactment” (Hayles 1999). It aligns with Varela's biologist view, where experience comes from having a body that always is embedded in an extensive biological, psychological and cultural context (Varela et al: 1991). Agency is a product of this process of enactment, or ‘enaction’, rather than a ‘virtue’ that can be possessed or programmed. In Karen Barad's performative account, agency is “a matter of intra-acting; it is an enactment, not something that someone or some thing has” (2003). The becoming of agencies and bodies (matter) is mutually entangled—agency is enacted through the dynamic encounter of bodies, while, at the same time, bodies are produced and transformed in this “congealing of agency” (Barad 2003). Similar to the Dynamical Systems view, these material enactments may involve humans or nonhumans, however the materialist feminist perspective challenges not only Cartesian objectivity but unsettles a range of ontological boundaries, deeply ingrained in the Cartesian tradition of modern epistemology, such as human–nonhuman, culture–nature and social–scientific.

“The separation of epistemology from ontology is a reverberation of a metaphysics that assumes an inherent difference between human and nonhuman, subject and object, mind and body, matter and discourse. Onto-epistem-ology – the study of practices of knowing in being – is probably a better way to think about the kind of understandings that are needed to come to terms with how specific intra-actions matter” (Barad 2003).

Our installation work *Zwischenräume* (Interstitial Spaces) is concerned with the intimate complicities that connect us with the machinic ecologies we create. It develops an unusual concoction of walls, curious robotic agents and surveillance technology to explore the performative potential of the unfolding material pluralogue. The charged terrain of the wall becomes the site for this unusual material encounter, playing out the co-dependant agential relationship between humans, machines and their environment. The installation couples curious robotic agents with our built environment by embedding robots into the architectural skin, sandwiched between the existing wall and a temporary wall that resembles it. Each machine agent is equipped with a motorised hammer, a surveillance camera, and a microphone to interact with its environment and network with the other machines. The hammer is not only used by the robots to pierce holes for the camera eye to see what's going on outside but also for communicating amongst the collective. The walls' and the machines' anatomy intertwine, turning the wall into the machine's brittle skin, and the machine into the wall's kinetic organs. The wall-body is the milieu through which the machines intervene and develop and express their desires through knocking, chipping, and punching holes, and adapting.

The machine-augmented environment embodies the agents in the terrain they survey; they are programmed to be curious and are thus intrinsically motivated to explore and transform their environment. The means of marking and exploring have been adopted from two military references, that of urban combat and visual intelligence. Movements, colours and faces are processed to create an adaptive model of the surrounds that allows the robotic agents to expect learned behaviours and proactively intervene. To these curious machines, learning and adapting are not goal driven but evolve based on what they discover and interpret as 'interesting'. The intrinsic desire to learn about the world directs both the system's gaze and its actions, resulting in a feedback process that increases the complexity of the environment relative to the perceptual abilities of the agent. Literally carving a trace of their curiosity into the wall, their desire to look is acted out in the open and manifests materially. They also communicate their state of arousal physically by re-sculpting their environment, rather than using an electronic network. Equipped with contact microphones to listen into the wall and sense the knocking of other robots, they use different knocking signals to rhythmically express excitement (high levels of sustained interest) or frustration (low levels of interest for a certain period of time). The embodied agents act and adapt through their intra-actions with their surrounds; shaping what they 'desire' to create or perform. At the same time, they become and are stimulated by what they shape.

When shown for the first time (figure 1 and 2), the gallery space was bound by glass walls, requiring us to not only stage the intervention but also the environment to be intervened with. The transparent space was turned inside out to present a private, cosy, living room scene oriented towards the public space outside the gallery. The machinery attached to the temporary walls inside the gallery transformed the living room scene into a capricious voyeur that drastically transformed the space over the course of three weeks. While the implicit theme of surveillance and voyeurism is not the focus of this paper, it is worth noting that the enactment and embodiment of the power of the machinic gaze was at the heart of *Zwischenräume's* conceptual development. Yet while the voyeurism enacted by *Zwischenräume's* robotic actors relies on visual intelligence, the work defies military logic of suspicious behaviour and rather promotes the machines' capability to seek difference for the sake of being different (Gemeinboeck & Saunders 2011). The machines' motivation to seek difference for the sake of difference, rather than for the purpose of othering that which is different, sets the tone for an alternative investigation into the politics of surveillance and its material affect. It isn't as simple as incriminating or trivialising the machine. The mingling of agencies and materialities in our installation and the way in which the audience is implicitly implicated, rather than invited to control the course of events, intimates the heterogeneous nature of surveillance. Thus, it is not the spectacle of the intervening machinery that we are interested

in, but rather the spectacle of the mutual processes this intervention unfolds as it foregrounds the material ecology of this machine augmented environment and its ongoing becoming.

The structural coupling of machinic agents and our built environment politicizes the matter of material agency and aims to foreground the performative potential of Dynamical Systems. Looked at from an expanded, ecological perspective, the work enacts what Jane Bennett describes as “an encounter between ontologically diverse agents, some human, some not, though all are thoroughly material” (2010). *Zwischenräume*’s drama features the encounter of two nonhuman agents, both human-made artefacts, one imbued with (artificial) intelligence and an ability to be proactive and the other designed to be inert and deprived of any vital qualities. We were interested in the co-dependent nature of this assemblage of forces, and the affective relationship through which it evolves. The structural coupling of machine and environment sets in motion their path of material becoming; both evolve through continual adaptations to compensate for the mutual perturbations. The process opens up the transversality of assemblages that owe their agential forces to the vitality of the materialities and dynamic spatio-temporal relations that constitute them (Bennett 2010). It’s a performance that always unfolds in the present, without the comfort of rehearsal. Rather, as Matthew Fuller argues, “the process of becoming that is machinic heterogenesis has no plot, as in story or territory, only a “middle,” an ongoingness: It cannot be turned into a standard object, it must be done” (2005).

The new assemblage not only challenges the structural integrity of the wall but also intervenes into the socio-politics of our third skin, laying open its vulnerabilities to continuous perforation. While perhaps the machine-wall couple seems purely destructive at first, together they unsettle the politics of the wall and turn it into a negotiable playground. Looked at as actors, they have much in common: both are as much technological as they are cultural; each models nature. The dynamical system underlying the first is inspired by the observation of the animal, while the latter renders the cave efficient, mobile, and mass producible. Both are ambiguous with regards to their acting: the machine empowers some and deprives others; the wall includes some and excludes others. Both extend the human: the machine is an extension of both, mind and body, while the wall is our extended skin. And yet, the dynamic agential forces of the machine are much closer to the human. We are more empathetic to, and at the same time, threatened by them. We (Westerners) cannot perceive the vital qualities of the wall, whereas the embedded machines can render it alive. The performativity of the machinic wall is further complicated by the machines’ autonomy; the self-motivated act of destructing the wall, the self-motivated act of looking. This is where it gets uncanny. It’s ok if the machines act on our behalf, and we control the machine that deconstructs the wall or if human governance drives the machine’s eye. Yet intrinsically motivated agents exhibit a higher degree of autonomy than agents motivated by an external human agent. The meaning of agency changes drastically, once the human actor can no longer control the human-machine-environment coupling. The discomfort of this shift, of course, reaffirms the segregation and hierarchisation of these actors. Neither the machines nor the wall exist outside the realm of human culture, and the autonomy of the machine is simply stretching its capacity to extend the human further: its intrinsic motivation, even if artificial and perhaps alien, is still modeled by a human agent, as is the design of its material embodiment.

This stretching quality was exactly what we aimed for with *Zwischenräume*, allowing us to stretch into the environment, to intra-act, not as the isolated and superior human but as part of a bigger assemblage. Coupling autonomously performing agents with our built environment opens up a space for Barad’s ‘congealing of agency’ (2003) where the different agential forces not only co-evolve but potentially conspire and perform together. All actors involved are vital players, entangled in a complicated

web of connections and specificities. While non-anthropomorphic, the material embodiment of the machines' cognitive processes and desires places them in a realm, where we (humans) can share and bodily experience them. The unfolding relationship between audience, machines and other matter, materialises a slice of our machinic ecology and makes tangible our position within.

DIGITAL ETHOS: TRANSFORMATIONS IN CONTEMPORARY PHOTOGRAPHY AESTHETICS SUBSEQUENT TO COMPUTATIONAL ART

MURAT GERMEN

Digital photography allows artists to think in a more daring and free way. This freedom influences the content, visual aesthetics of artworks in contemporary photography, which is influenced extensively by digital creativity. This paper will focus on the significance of digital technologies in changing aesthetics, planning, vision, fiction, realization of photography and avant-garde photography forms nourished by digital culture

INTRODUCTION

Photography is one of the creative fields at which technological advances influence artistic expression the most. The ease of manipulation brought by software and extra features available in cameras made artists using photography reconsider their visions, themes, narration, syntax and ways of sharing their artwork. Sharing sites like Flickr, which expedite encounters of various individuals from different cultures, help in changing the perception of the much vital notion of time and enable artists to get faster feedback, revelation, exposure and layering of information to be conveyed.

While some photographers, who are deeply obsessed with analog processes, deny digital technology; it is quite obvious that artists, who are aware of the complexity and particular advantages that this technology brings, indeed end up with a novel aesthetics of photography. In addition to the regular montage and collage methods remaining from the old analog days, digital imaging techniques allow artists to work with notions like augmented perception, chronophotography, surrealism, pictorialism, superimposition, simplification, creation of new worlds, appropriation...

AUGMENTED PERCEPTION

“Without perception there is no art. A work of art is an organized array of sensory stimuli if, therefore, the senses are not stimulated, then the true work of art does not exist for the observer.” (Wise 19)
 Though there are studies on exceeding human sensory capabilities, our visual perception still takes ‘what the eyes see’ as the basis of apprehension. In this case, artists who intend to go beyond what one can see with the naked eye, take advantage of software. These digital means enable artists to assemble and convey information in a holistic manner that is otherwise not possible to record in a single photographic documentation act. The resulting totality leads to a particular aesthetic form which turns out to be the synthesis of individual forms, in other words a ‘sui generis’ situation. One can interpret this as a cubist approach.

If we consider the present digital platforms we use, various tools of social media on the other hand; “literacy, TV, computer games, the Internet—all play a role in shaping how we think. Technology is never innocent—we develop it and use it, and in turn it shapes us. [...] Technology allows one to have experiences far beyond what are supported by the normal human physiology. Sternberg and Preiss examine the implications of technology on cognition. When technology is broadly conceptualized as ‘the building of artifacts or procedures-tools-to help people accomplish their goals,’ then the influence of technology on human development is as old as humanity. [...] At the very least, it is becoming increasingly obvious that technology is altering mental functions (Sternberg & Preiss, 2005).” (Gackenbach 346)

This alteration takes us to the notion of cyberception which is, after Roy Ascott, “the emergent human faculty of technologically augmented cognition and perception.” Cyberception carries the potential of laying a firm basis for the development of higher states of consciousness, i.e. augmented perception. This is why the congruence between computational and human behavior appeals to the artist and helps in augmenting his/her intuitive gift to generate aesthetic form. Andreas Gursky, one of the leading photographers of the much respected Düsseldorf photography school of Bernd & Hilla Becher, Chris Jordan of USA and French photographer Jean-François Rauzier take advantage of digital imaging and post-processing in order to take his work to a level that cannot be realized otherwise.

PICTORIALIST TENDENCIES

There is a never-ending relationship between photography and painting. When photography was invented, it took painting’s function of recording history and was more trusted as a documentary tool since it witnessed experiences more realistically than paintings, which are actually constructs from scratch. Later photography proved its independence and stopped being seen as pure evidence. This is when it found the opportunity to act like painting and be taken as an apparatus of fiction. This new relationship gave birth to ‘pictorial’ photos that emulated optical qualities of paintings, which in turn paved the path to hyper-realistic paintings that are easily mistaken for photos.

If we look at the early stages of this relationship; “by the last quarter of the 19th century, photographers around the world had supplied ample proof of the camera's unique ability to record people and places. At the same time, there were others who were taking pictures for a different purpose. Convinced that the camera could be used to go beyond simply recording what was in front of the lens, these photographers, both amateur and professional, were determined to produce images of artistic merit. [...] Their aim was to convince art critics, other photographers, and the general public that photography should be regarded as a legitimate form of art. [...] At the time, people regarded the world's great paintings as the highest form of visual art. It was only natural that artistic photographers began by trying to produce the same kinds of images as those created by the greatest artists. They chose the same types of themes, settings, and compositions. Like painters, they emphasized the contrasts between dark and light tones (called *chiaroscuro*). [...] Perhaps the most distinguishing characteristic of this early artistic movement was the way in which many photographers manipulated their images.” (Sandler 57) Henry Peach Robinson's book ‘Pictorial Effect in Photography,’ published in 1869; referred to this movement, influenced by the ‘photography-as-art’ approach, as pictorialism.

The intimate connection between painting and photography is still so strong that many contemporary photographers like Helena Blomqvist (Swedish), Désirée Dolron, Jasper de Beijer (Dutch), Christian Noirfalise (Belgian), Yao Lu, Lu Jun (Chinese), Nazif Topçuoğlu (Turkish), Alessandro Bavari (Italian) are taking advantage of the digital imaging technologies in order to create photos that resemble paintings. “Peter Bunnell, in his work titled ‘A Photographic Vision: Pictorial Photography 1889-1923’ (1980), associates the antiphotographic art photography known as ‘pictorialism’ with a reaction against ‘the dehumanizing effects of science and applied technology.’ Pictorialism, he adds, placed ‘its greatest emphasis on the individuality of the artist as witnessed in the work of art and idiosyncrasies of its production.’ ” (Sternberger 37)

PALIMPSEST-LIKE SUPERIMPOSITION: LAYERING TRANSPARENCIES

A palimpsest (Greek “palin,” again; “psēstos,” scraped) is a re-used papyrus or parchment manuscript in which the original text has been washed or scraped off and a new one substituted. The modern version of this archaic surface of knowledge which allows accumulation of information is the Photoshop canvas, where you can completely cover a layer behind yet still make some details emerge from beneath. This possibility of layering various data from different sources one on plane is a more complex form of the good old analog collaging & montaging methods and enables artists to reach a richer expression through superimposed pluralities.

German artists Elger Esser, Kay Kaul and Michael Najjar, Turkish artists Murat Durusoy and Zeynep Kayan are among numerous photographers who benefit from superimposition, in which various images become interwoven into a reassembled complex fictive entity as a collage that brings memories and places together in one plane.

INCLUSION OF TIME AS A NARRATIVE TOOL

Period(s) included in single photographs are usually and naturally much shorter than periods documented in video works. Yet, when it comes to combining photos taken at different times on one photographic surface, it becomes possible to see remnants of longer periods of time. Performing time lapse photography and compositing images as a durational pattern of many traces left by different moments,

lead to the positive notion of timelessness (lack of time dependence) due to the plural presences of time at once. Substance becomes multi-layered and hierarchy disappears: All elements are relatively equal parts to the whole.

An accumulated photographic rendering of one place with various lights, movements, figures, facets, objects and subjects coming from discrete slices of time, allows a richer visual definition of the particular milieu that can be a more faithful description of the observer's personal experiences. The resulting images after such accumulations are usually visual experiences impossible to the naked eye.

Ahmet Elhan of Turkey, Pablo Zuleta Zahr of Chile and Thomas Weinberger of Germany are some artists who manipulate the perception of time by incorporating distinct phases of moments purposefully selected from the chronological continuum.

SIMPLIFICATION AS AN ELUCIDATION TOOL

Even though the presence of the traces from different times can help artists to improve their expression, it is also possible to take a completely opposite direction and take information out from a single layer of time. This subtractive approach limits duration to an even smaller fraction of time, to the degree it does not exist. The lack of detail is not meant to hide information from the audience, but rather to enlighten artistic expression and make viewers focus on a particular content more easily. Following Mies van Der Rohe's famous quote; "[sometimes] less is more..."

Above mentioned simplification can be obtained by erasing the signs of specificity and turning it into anonymity, potentially pointing to the banality of our homogenized environments. An alternative way is to remove the traces of typical presence in order to create a disturbing sense of absence where existence and attendance are normally expected. These exclusions of native details from recorded reality that may lead to floating components that are isolated from their contexts, challenges our view of the reliability of photography and our concept of the space represented by it. Jesper Rasmussen (Danish), Josef Schulz (German), Matt Siber (American) are artists who use simplification in order to clarify what they want to convey through their photographs.

THE ANTI-REAL: SURREALISM IN PHOTOGRAPHY

Photography for some, is reflection of reality. Yet, the illusion of a single reality, is criticized by W. Flusser: "The [observer] trusts [technical images] as he trusts his own eyes. If he criticizes them at all, he does so not as a critique of image, but as a critique of vision; his critique is not concerned with their production, but with the world 'as seen through' them. Such a lack of critical attitude towards technical images is dangerous in a situation where these images are about to displace texts. [It] is dangerous because the 'objectivity' of the technical image is a delusion. They are, in truth, images, and as such, they are symbolical..." (Flusser 2000) Some artists take this critical attitude to an extreme to defy Reality and create a new synthetic reality.

Quoting the Wikipedia definition, "surrealist works feature the element of surprise, unexpected juxtapositions. [...] Surrealism would advocate the idea that ordinary and depictive expressions are vital and important, but that the sense of their arrangement must be open to the full range of imagination. [...]"

Freud's work with free association, dream analysis and the hidden unconscious was of the utmost importance to the Surrealists in developing methods to liberate imagination." Artists using digital techniques to take photography from realism to surrealism, aim to free people from false rationality, restrictive customs / structures and prejudice.

Ryuta Amai (Japanese), Michael Najjar, Loretta Lux (German), AES+F (Russian), Anthony Goicolea (American), Ruud van Empel (Dutch) are among artists who produce startling, otherworldly surreal images which involve composite elements culled from different settings, figures, cultures, individuals and combine them into new topographies, characters and scenarios.

APPROPRIATION

The complex notion of appropriation is straightforwardly defined by Mikhail Bakhtin: "The word in language is half someone else's. It becomes one's own only when the speaker populates it with his own intention, his own accent, when he appropriates the word, adapting it to his own semantic and expressive intention. Prior to this moment of appropriation, the word does not exist in a neutral and impersonal language, but rather exists in other people's mouths, in other people's contexts, serving other people's intentions: it is from there that one must take the word, and make it one's own." (Bakhtin 1981:294)

Art is such a field that one can easily borrow an idea, artwork, approach and use it/them in his/her work, with the condition of quoting the reference in ideal conditions. Very famous works like "Las Meninas" by Diego Velázquez have been reinterpreted in the form of "hommage à ..." by very famous artists like Pablo Picasso and Joel Peter Witkin. In photography, people like Thomas Ruff buy the copyrights of old photos taken by another photographer and retouch them in Photoshop, color them partially and finally transform them into their own artworks. In a recent series called 'JPEGs' (2004-9) Ruff uses readymade JPEGs by exploiting the lossy compression of visual data into spoiled artifacts. Ruff blows low quality low-res files up in order to reveal how much information is lost already before images are served to people and become iconic in world history. These images, blurred due to extreme up-scaling, are somewhere between legibility - illegibility and point to the skepticism that people should adopt against images that are supposed to convey actualities of world news.

CONCLUSION: CREATION OF A NEW WORLD

Mark Kingwell asserts that "photographs are not multiple depictions of some single reality, waiting out there to be cornered and cropped, and somehow regulating, even in the cornering and cropping, how / what the image means. Rather, photographs offer multiple meanings. The presented image is not a reflection, or even an interpretation, of singular reality. It is, instead, the creation of a world." (Kingwell 2006)

Truth with the capital T is not taken as the departure point in this paper; on the contrary, personal delinquencies of temporary yet experienced smaller realities is suggested. Digital tools available for photography allow the artists in the field to think in a more daring and free way. This freedom influences the content and also the visual aesthetics of the recently created artworks in the universal practice of contemporary photography. Photography is probably one of the visual art platforms that is influenced the most

by digital production and creativity. Fortunately, it seems it will continue to be so in the future and digital means will strengthen photography's position in the art world as one of the most progressive expression platforms.

DIGITAL PHOTOGRAPHY: EXPANDED CREATIVITY AND TECHNOLOGY

Murat Germen

Digital tools available for photography allow artists to think in a more daring, free way. This freedom influences the content and also the visual aesthetics of the recently created artworks in the universal practice of contemporary photography. Digital means/processes are already and will in the future, strengthen photography's position in the art scene as one of the most progressive artistic expression and visual language platforms.

Photography is one of the creative fields in which technological advances influence artistic expression the most. The ease of manipulation brought by software and extra features available in cameras made artists (using photography as an articulation tool) reconsider their visions, themes, narration, syntax and ways of sharing their artwork. Sharing sites like Flickr, which expedite encounters of various individuals from different cultures, help in changing the perception of the vital notion of time and enable artists to get faster feedback.

Digital tools allow photographically based artists to think in a more daring and free way. In addition to the regular montage and collage methods remaining from the analog days, digital imaging techniques allow artists to work with notions of augmented perception, chronophotography, subreal encounters, pictorialism, palimpsest-like superimposition, interlacing, simplification / minimization, creation of new worlds, delusion, synthetic realism / artificiality, appropriation.

Following textual content are excerpts from the concept statements of various artwork series in which computational procedures were essential in their creation.

Aesthetics of serendipity: Muta-morphosis

The different traces left by various people and slices of time co-exist as layers in cities that have a particular past. The global trends and economical conditions strain this multi-layered traditional urban structure. An architecture with a language that cannot be considered as local anymore but universal, attacks the old texture of cities during the urban growth. This intervention usually implemented through gentrification supported by big capital, causes the urban tissue and its components to face mutation and even

beyond this, undergo metamorphosis. Following this interaction and consecutive natural selection, some constituents disappear and some survive after being transformed.

The concept of “muta-morphosis”, a combination of the notions of mutation and metamorphosis, and the connected artwork series was obtained by reducing panoramic images on one axis. The image compression on the horizontal level points to the dynamics between the urban components that can persist and the ones that give up, vanish in the various historical, residential and business urban districts. The visual urban result obtained after this contraction process points to the much discussed notion of evolution, where stronger components of existence survive the others after a natural selection process and change the course of life. The lack of a single perspectival structure due to multiplicity of perspectives after panoramic imaging, can be linked to Ottoman miniatures, which in turn, connects the global contemporary representation to its local traditional counterpart.

Contemporary aesthetics is a subject under construction due to the rich variety of fresh expressive means supported by the computational creativity, nourished by artistic spontaneity and improvisation. The series ‘Muta-morphosis’ could only be created within the digital realm, and it indirectly points to the mutation and metamorphosis in aesthetics in general.

Photography as a tool of Alienation: ‘Aura’ series

Regular photographic imaging record volumetric planes with smooth surfaces. The reason is the camera’s deficiency in perceiving and documenting the visual richness of “persuasive” details in life. HDR imaging methods used in creating this artwork series titled “Aura” helped making invisible organism-like textures emerge and point to the notions of decay and symbiosis.

The ‘Aura’ series consists of photo-composites obtained with the combination of Photoshop and Photomatix Pro in order to perform HDR imaging. Four or more photos from the same angle are used for each of the plates from the series. All multiple-photo groups, recorded inanimate objects still, yet animate subjects in different positions / movements due to passage of time and slow shutter speeds. Superimposition of four photos resulted with the particular aesthetics of the constant appearance of immobile objects and the dynamic intricacy as a consequence of layered mobile subjects. The aim in multiplying the photographic renderings of these mobile subjects, is to reach a similar complicated result to the above mentioned notion of merging reflective analogue visual data with its reflexive digital one.

This series of artworks, focusing on the difference between the intrinsic soul and extrinsic perception subsidiary to conditions; was created in galleries, museums and market places in Paris, Bologna, Hong Kong, London and Istanbul in year 2009. The work is conceived as a reminder and critique of the ever-present but recently much-peaked “market economy” climate and approach, concealed with various awareness arguments in artists’ statements. In the presence of commercial art milieu, it seems there has not remained much difference between art venues and shopping malls. Aura series can be taken as a study created after the desire of having artworks independent of peripheral conditions and gaining their inherent value...

Inadvertent Art - Ars Accidental

Even though art is the product of an intentional act of fabrication, the serendipitous spill of an ink or paint, the unforeseen slip of a pen or brush, sudden shake of a camera in the analog realm have the potential of generating an unconscious lead in the planned course of action. The consequential shift in direction may completely change the aesthetics and content of an artwork. An artist should always be open to such 'accidental' dimension which will help him / her to take the original idea out of its initial framework and recontextualize it for a new conception.

The outcomes of software 'failures' in digital technology made a similar type of aesthetics emerge: Glitch aesthetics. The 'dirty' and sometimes 'chaotic' nature of glitches made things look much more organic and human, as opposed to mechanically computerized. This unrefined aesthetics has recently become so popular among designers that some of them have made specific websites as tributes to the process.

Though the accidental dimension in art looks more compatible with analog practices, there are various instances it finds its niche in the digital world as well. Mystifying benefits like freedom from preconceptions, momentary skepticism about planned course of action, avoiding mechanical thinking / prejudices, reaching a more natural / authentic result, discovering unusual and unique aesthetical domains, etc. will always make 'ars accidentalis' an indispensable part of art practice.

Conclusion

Digital tools available for photography allow the artists in the field to think in a more daring and free way. This freedom influences the content and also the visual aesthetics of the recently created artworks in the universal practice of contemporary photography. Photography is probably one of the visual art platforms that is influenced the most by digital production and creativity. Digital means/processes are already and will in the future, strengthen photography's position in the art scene as one of the most progressive artistic expression and visual language platforms.

PERIPATO TELEMATIKOS

Greg Giannis

Peripato Telematikos explores walking performances as a means to (re)present our environs, challenging what we know about the places/spaces we inhabit and our relationship with them, and provides a means by which audiences can engage with these performances in real time.

All texts are available online at <http://www.peripato.net> I have included the cartography text for this paper.

Cartography

New technologies have the ability to create highly accurate representations of our physical surroundings but they also present us with the opportunity to express location outside of standardised forms and re-instill subjective articulations of space. Harvey quoted in (Ota 2008)

This project creates subjective mappings through collective and individual staged walks. The mappings are generated in real-time and consist entirely of media that the walker submits through their mobile recording device. As the intent is to create mappings, I was interested to know the cartographic discipline's current thinking on mapping and it seemed remiss to not take this into consideration. The research revealed a crisis in this discipline. The open access to satellite imagery merged with electronic databases is superseding conventional maps.

In his recent chronicle, *The Mapmakers*, John Noble Wilford notes that digital technology has brought about a revolution in the way maps are created and used that is without precedent since the Renaissance. [... M]apping technology has split the interface from the database, a split comparable to the liberating effect photography had on the development of painting. Before the advent of aerial photography, satellite tracking and computerized data-gathering, a map was expected to represent its territory with comprehensive accuracy. Freed of that responsibility, cartographers can manipulate their data into any number of visual representations - an act so potent it has attracted the attention of other disciplines. As Harley remarked, 'Maps are too important to be left to cartographers alone' (Abrams and Hall 2006) p 12.

Mapping has attracted the attention of the art world, which has been a fertile ground for experimentation with maps, and this has come to the attention of the cartographic discipline. There is so much activity in this area that Woods has remarked:

[T]here is a cresting wave, and it awaits skilled surfers (Cosgrove 2006)

This is a quote from a 2006 special issues of *Cartographic Perspectives* (the journal of the North American Cartographic Information Society) on art and maps. The special issue gives a good summary of the current intersections of art and maps and notes its prevalence, but itself also signifies the importance of the work being conducted in these intersecting fields. At the end of this section, I provide examples of artists working with maps.

The art world's response addresses some of the contemporary concerns surrounding maps and their use. The cartographic community itself, as mentioned previously, is leading a call for experimentation in the visual forms of maps, given that it is now freed of the responsibility to represent space with accuracy. Furthermore, the cartographic community is acknowledging the inherent subjectivity of maps and, given that accurate representation of space is now accomplished by satellite imagery, is looking to rein-still subjective articulations of space. Historically maps purported to be objective, but their subjectivity is now well understood, and they have served to support imperialist expansion and other forms of control.

As an instance of the 'microphysics of power', the imposition of rational order upon space is 'the minuscule and ubiquitously reproduced move of 'gridding' (quadriller) a visible space in such a way as to make its occupants available for observation and 'information' de Certeau quoted in (Stott 2005)

In response to this controlling view of the world from above, mappings are being constructed from the perspective of the person on the street. This raises the possibility of mappings that are created by many, from a multiplicity of viewpoints, and not by a single, overarching authority. This controlling view from above has been facilitated by the striation of the earth's surface using a grid of lines of longitude and latitude, an inseparable component of maps. This grid is encapsulated in the contemporary world by the GPS system, referred to by some commentators as the 'Imperial grid' (Holmes 2004). In *Parables for the Virtual*, Massumi argues that if one reduces the systems of meaning to positions on a grid, one denies the very variation and transition inherent to those systems of meaning. The GPS system is one of many technologies that have radically changed contemporary western society, allowing anyone to pin point their position, or the position of others, on the earth's surface with considerable accuracy. But modern technologies raise other issues for mapmakers. We live in a world characterised by 'speed, fluidity and ephemerality of contemporary means of transport, communication and media technologies' (Stott 2005). How are these factors to be accounted for in maps of the contemporary world? How can a map incorporate time? How can we free ourselves from the imperial grid?

CONCERNS OF CARTOGRAPHIC DISCIPLINE.

As mentioned previously, the cartographic discipline is in crisis. Its role in providing accurate maps has been superseded by satellite imagery combined with online databases. Their response has been to encourage a subjective, socially inclusive cartography, to bring to the fore that which has thus far been omitted from maps, to encourage experimentation with map forms given their emancipation from having to provide accurate representations, and to explore possibilities for mapping to represent a fluid, ephemeral, dynamic world; what static representations are unable to do. As noted by Lippard, this response is not entirely new, and perhaps those that led this call in the sixties, did so in anticipation of the current problems with cartography.

The mapmaking process can also bring together disparate elements in a community. In the sixties, geographer William Bunge proposed a 'Society for Human Exploration' that would map from different human viewpoints, including children's. [...] Local people would lead expeditions to create 'oughtness maps,' whose goals were to change rather than merely map the world. (Lippard 1997) p79

This opens the way for maps to articulate a subjectivity missing from maps from the:

time of the Renaissance as new objectivity and functionality began to enter map making techniques leading to the standard of map we have today — 'maps stripped of all elements of fantasy and religious

belief, as well as any sign of the experiences involved in their production had become abstract and strictly functional systems for the factual ordering of phenomena in space.' (Ota 2008) p361-362

In contrast to the maps we have today, this project's mappings are totally constructed of the experiences involved in their production (i.e. staged walks), and make no attempt to factually order space. I proposed a subverting of the map, by creating a (re)presentation from the view point of ground level; a montage of media fragments. This builds on de Certeau's proposal that place is defined by urban planning but transformed into a space through the act of walking:

space is composed of intersections of mobile elements. It is in a sense actuated by the ensemble of movements deployed within it. [...] In short, space is a practised place. (de Certeau 1984) p117

The mappings are constructed totally by media that the walker submits through their mobile recording device. Not the 'voyeur' who is 'at a distance' and thus 'a solar Eye, looking down like a god' who 'must disentangle himself from the murky intertwining of daily behaviours and make himself alien to them'. (de Certeau 1984) p92-93 The walker makes no pretence to mapping a totality, objectivity, or ordering space. Her intervention is one that is very localised and amongst the 'murky intertwining of daily behaviours.' This raises the possibility for mappings to articulate knowledge that isn't solely about ordering space, but a multiplicity of concerns. For example:

MILK [a project by Ieva Auzina and Esther Polak traced the path of milk from its origins in the udder of a cow in rural Latvia to a cheese vendor in the Netherlands] suggests a powerful vision of how locative technologies could allow one to more fully understand how products are commodified and distributed through the actions of global trade, thereby making visible the networked society. ... [W]hen tied to a materialist vision, the recent turn to maps is among the strongest critiques of globalization available to us. Recognizing this, philosopher Alain Badiou referred to the maps of power drawn by artist Mark Lombardi as 'the creation of a new possibility of art and a new vision of the world. (Tuters and Varnelis 2006).

Here we have two very divergent manifestations of mapping. MILK provides a glimpse of the networked society through tracing the path of a basic food product, whilst the maps drawn by Lombardi visualise the networks of power, corporations and the military.

Perhaps the biggest of all challenges is to map '[t]he complexities of the contemporary world – those of financial markets, information networks, social relations, etc. – [that] are said to be 'unfigurable', opaque and unrepresentable.' The map 'must account for the speed, fluidity and ephemerality of contemporary means of transport, communication and media technologies.' (Stott 2005) How can a map be dynamic? Any representation that is static is fixed in time, and represents a snapshot of its subject at a particular point in time. In order to incorporate time, the medium itself must have this faculty. Paper is out of the question (for the moment at least) whereas networked media such as the Internet is the most suitable candidate.

The mappings produced for this project are accessed on the Internet. The constituent components are stored in an online database, and are extracted from the database and presented in ZUI, whenever a mapping is viewed. As is the case with satellite maps, the interface is split from the database. The interface serves all mappings, each differentiated by the constituent components that together comprise that mapping. The constituent components are added to the database over time, and can continue to be

so indefinitely. Unlike static representations these mapping can change over time, opening up the possibility to represent the 'unrepresentable' complexities of the contemporary world.

As mentioned previously, this project's mappings are implemented in such a way as to allow unrestricted manipulation of the constituent components so that the mappings are mutable. All uploaded elements are available for further manipulation. Their position (x, y and z-planes) in the interface is variable. Visitors to the site are able to move these elements and create associations between elements and group others. As a result, the mappings are not fixed in time or spatially. All the constituent components can be added over time and subsequently moved in relation to one another, further complicating the idea of a 'map', but coming closer to the Deleuzian notion of a map:

Make a map, not a tracing.... What distinguishes the map from the tracing is that it is entirely oriented toward an experimentation in contact with the real. The map does not reproduce... it constructs.... The map is open and connectable in all of its dimensions; it is detachable, reversible, susceptible to constant modification. It can be torn, reversed, adapted to any kind of mounting, reworked by an individual, group, or social formation. It can be drawn on a wall, conceived of as a work of art, constructed as a political action or as a meditation. (Deleuze and Guattari [1980] 1987) p12

The tracing that Deleuze refers to is what we have come to know as the base map. It represents extant knowledge and therefore proposes nothing new, simply a reiteration of existing ideas. The base map has also been dispensed with in this project's mappings. If we are to accept that current mappings represent a Cartesian and static notion of space (Sant 2006) p 99 then to simply take an existing map and overlay it with subjective content only reinforces this. We are still dealing with the same base map, with all its inherent problems, the only difference being that it is now annotated with subjective information:

Current collaborative mapping projects using locative media technologies have often overlooked the conventions of the base map as a site for reinvention. Although these projects are ambitious in their aim to propose alternative organizations of urban space through the way it is digitally mapped, they remain bounded by datasets that reinforce a Cartesian and static notion of urban space.

[...]

Although many collaborative mapping projects undermine their own base maps by layering them with collectively defined concepts of space; including participants' emotions, itineraries and memories, these annotations are inextricably linked to the predefined foundations of the map they overlay. (Sant 2006) p 99-100

In some instances, the mappings serve to embed media into place. Subsequent visitors to these sites, with the correct equipment, are then able to retrieve the media left by the mappers:

Geograffiti (CN/UK) and GeoNotes (SE) ... seek not to document or interpret the environment but to embellish it with digital graffiti or virtual tagging as expressive mark. (Hemment 2004)

This has obvious applications for audio-guided tours, which is already widespread. Outside of the media art world, artists work with maps in ways that are less reliant on the base map, many dispensing with it altogether. Casey's *Earth Mapping* gives many examples.

Aside from reinforcing a Cartesian and static notion of space, the base map, with its reliance on the grid, can be seen to be reinforcing a static notion of thought:

When we think of space as 'extensive,' as being measurable, divisible, and composed of points plotting possible positions that objects may occupy, we are stopping the world in thought. We are thinking away its dynamic unity, the continuity of its movements. We are looking at only one dimension of reality. (Massumi 2002) p 6

For Massumi, this reliance on the grid represents a far greater problem as it stifles the potential for change and looks at the world in a way that restricts possibilities.

ART AND MAPPING

Artists are harking back to the premodern, subjective map that 'concentrated on geographical meanings' and offered 'as full an impression as possible of the lived texture of the local landscape'. (Lippard 1997) p 81

Jameson concludes that 'the political form of postmodernism, if there is any, will have as its vocation the invention and projection of a global cognitive mapping, on a social as well as a spatial scale.'

[...]

There would be virtually no end to a list of every artist, literary critic, critical theorist, art historian, sociologist, or philosopher who globally or locally 'maps out' the contemporary cultural landscape. (Bosteels 1996, p 110)

- *Earth Mapping* (Casey 2005)
- Guillermo Gomez-Peña - placed South America at the top of a map (Lippard 1997) p 80
- Peter Fend - worked with Petersen projection (Lippard 1997) p 80
- Peter Dykhuis - exhibition of 'world views' during G7 summit in Halifax, world maps published by each of the G7 countries placed side-by-side. 'Seeing them all side-by-side, the differences between maps are striking. Aspects of their design and choice of colour seem to embody national stereotypes - the Japanese map looking understated, with light, cool colours, while the Italian map is bold and funky, with wildly curvaceous lettering. Each of these superpowers locates itself towards the centre of the world, and relegates the rest of the world more or less to the margins.' (Lippard 1997) p 80
- 'Florence Ladd asked a group of urban African American youths in California to draw maps of their neighborhood and received widely diverse interpretations.' (Lippard 1997) p 80
- 'Stanley ("this way") Brouwn - exhibited scribbled pencil maps made by people in Amsterdam from whom he asked directions to a well-known landmark.' (Lippard 1997) p 80.
- 'Working with only a biro and a camera, and with no knowledge of the area, Hugh Davies representing Analogue Art Map spent the 2006 Conflux Festival seeking hand drawn maps from locals in the Brooklyn NY area. These maps gave directions to sources of food, water and rest as well as to possible points of

interest. As each map begins where the last ended, the maps link together to form a linear journey or narrative told by multiple authors.' (Davies 2006)

SIMULATING SYNAESTHESIA IN REAL-TIME PERFORMANCE: USING SUBJECTIVE USER-INTERACTION MODELS IN 3D SPATIAL ENVIRONMENTS

STEVE GIBSON

In this paper the author will describe and show examples of his live audio-visual work for 3D spatial environments. These projects use motion tracking technology to enable users to interact with sound, light and video using their body movements in 3D space, simulating the effect of synaesthesia.

Figure 1: Virtual DJ, 2005. Steve Gibson, Live at Stealth Attack Nottingham, Incubation 2005 Conference. Photo by Jonathan Griffiths.

Figure 2 - Virtual VJ, 2011. Steve Gibson and Stefan Müller Arisona. Performed by Steve Gibson & Maria Lantin. Culture Lab CHI 2011 party, Emily Carr University of Art and Design, Vancouver, BC. Photo by Atau Tanaka.

Using the tracking capabilities of the *Gesture and Media System* - invented by APR of Edmonton, Canada - two or more users can use space as an audio and video remix or performance tool. The *Gesture and Media System* allows artists to "map" an interactive space with sound, light and images, and to have user-movement dynamically control these elements via small 3D trackers.

In the author's spatial projects audience members can interact with sound, light and video in real-time by simply moving around in space with a tracker in hand. Changes in sound, light and real-time visual effects can be synchronized with changes in sound and or light (i.e. music volume = light brightness = video opacity). These changes can be dynamically mapped in real-time to allow the user to consolidate the roles of DJ, VJ and light designer in one interface. This interaction model simulates the effect of synaesthesia, in which certain people experience light or colour in response to musical tones.

Synaesthesia

Synaesthesia is a condition in which a person experiences sensations from one sense in a second different sense. The likely most common occurrence is a description of colour related to musical tones. "How does it feel to hear music in color, or to see someone's name in color? These are examples of synesthesia, a neurological phenomenon that occurs when a stimulus in one sense modality immediately evokes a sensation in another sense modality. Literally, "synesthesia" means to perceive (*esthesia*) together (*syn*)." [1]

VIRTUAL DJ Concept

The original concept of *Virtual DJ* was to create a virtual room in which the audience could interact with sound and light by simply moving around with a tracker in hand. With an acknowledgement to the obvious connections with the earlier work of David Rokeby, [2] *Virtual DJ* is designed as a comparatively populist project, one in which the audience can interact in a very physical, almost aerobic manner to dance-oriented electronic music.

Virtual DJ uses two motion-trackers, one controlling drum and bass, and the second controlling melodies and samples. Certain motions have been standardised to create specific sound effects: raising the hand in the melody tracker usually results in a rising melody, raising the drum and bass tracker results in a change of drum patterns. Similarly lights are used to give the users a physical sense of the sound zones in the room: when users move within sound zones lights dynamically change in synch with their movements. This interaction model simulates the effect of synaesthesia, in which certain people experience light or colour in response to musical tones.

In *Virtual DJ* the 3D space has been mapped meticulously to allow users to have a satisfying interactive experience regardless of the style of their interaction. The spatial mapping was reworked based on the results from beta tests of hundreds of users over a two-three year period. These tests were both formal (i.e. measured beta tests in a controlled studio environment in which I wrote down user reactions and responses) and informal (i.e. resulting from a performance after which I arranged a follow up studio session with users).

Virtual DJ uses robotic lights to simulate the behaviour of humans and to represent human agency. The environment of *Virtual DJ* exists as a living, sounding space that behaves in a predictable manner in

relation to the user. To the casual observer it seems as if the space is alive; to the performer the precise matching of sound and light gives the air an almost tactile quality.

VIRTUAL VJ Concept

Virtual VJ takes the concept of *Virtual DJ* one step further and unites the role of the DJ and VJ into one interface: 3D space. The concept of *Virtual VJ* is to allow two users to control different aspects of the sound and video environment with their movements. One tracker is set to trigger sound and video and the other is set to manipulate the sound and video initiated by the first tracker.

The key conceptual idea that is explored is the idea of cooperation and the sense of personal space in ephemeral, virtual systems. This is achieved by programming the trackers so that dramatic events will happen when the two trackers are close together or at a distance. For example the environment has been programmed so that the trackers apply dramatic effects such as distortion to the audio when they are proximate to each other or reverb when they are distant from each other. This results in a game of cat and mouse in which the users determine whether they will choose to closely follow the movements of the other participant or pursue a more individual experience.

Enabling Subjective User Interaction In 3D Spatial Environments

Both *Virtual DJ* and *Virtual VJ* are based on the basic interface design strategy of using redundancy to enhance immediate user interaction. In common usage redundancy is often thought of a negative term, but in computer-controlled environments the use of redundant information in an interface design can often lead to greater user clarity, particularly when the information between mediums is sufficiently obvious.

In *Virtual DJ* lights and sound are matched very precisely. When a user perceives a change in sound due to a movement, the lights will change in a similar manner. This redundant information over the two mediums allows users to experience a more tactile sense of space and to more easily infer how their interactions are affecting the audio-visual environment. In *Virtual VJ* the redundant information is passed between the audio and video realms in a similar manner to *Virtual DJ*.

Similarly both environments have been mapped in a way that allows them to at all times produce a predictable result (i.e. in *Virtual VJ* raising the hands will usually produce a rise in volume and an increase in image opacity). At the same time users are free to roam wherever they wish, to combine audio and visuals in whatever manner they chose.

This predictability is in fact an asset in that it allows users to lose their self-consciousness when interacting: they do not fear playing “wrong notes”. This is in opposition to many similar environments in which users are often mystified by the interaction model due to a lack of spatial planning or an over-complex interaction model. On the other hand the spatial mapping in *Virtual DJ* is quite complex; in many areas of the room several parameters are changed simultaneously by different motions; however, because the changes are logically mapped to movements and the results are predictable and repeatable, users gain a sense of control that they would not otherwise have in more “randomly” mapped spatial environments.

Conclusion

Using a combination of motion-tracking with matched live video, sound and light, the artist can create the illusion of synaesthesia for participants and viewers. Users can intuit spatial interaction interfaces more effectively with redundant information programmed between the different mediums. This assists both users and viewers with interactivity in the unfamiliar medium of 3D spatial environments and helps establish formal and aesthetic meaning, and avoiding the pitfalls of random and over-complex interface design and programming.

ADVANCED MEDIA CONTROL THROUGH DRAWING: USING A GRAPHICS TABLET TO CONTROL COMPLEX AUDIO AND VIDEO DATA IN A LIVE CONTEXT

Steve Gibson & Justin Love

This paper demonstrates the results of the authors’ Wacom tablet MIDI user interface. This application enables users’ drawing actions on a graphics tablet to control audio and video parameters in real-time. The programming affords five degrees (x, y, pressure, x tilt, y tilt) of concurrent control for use in any audio or video software capable of receiving and processing MIDI data.

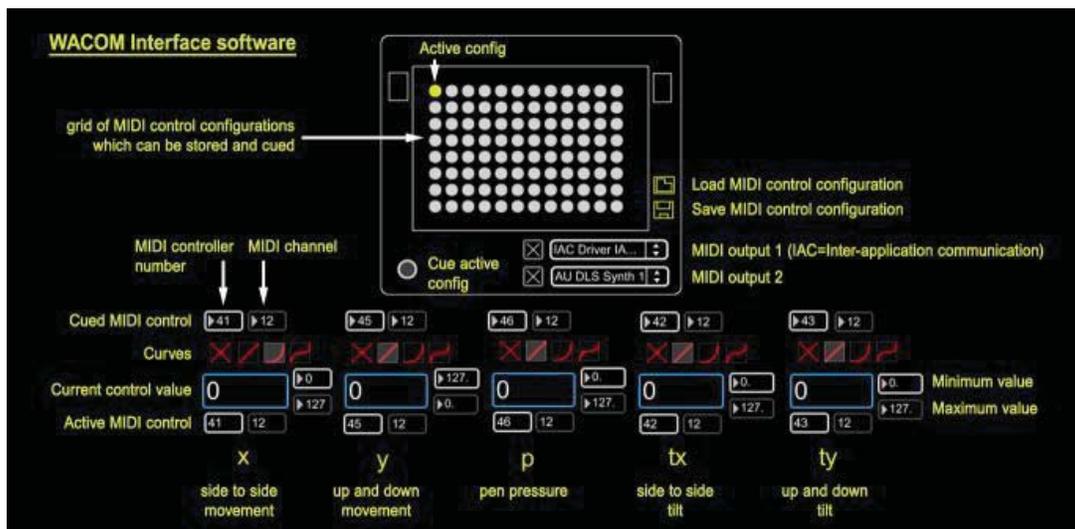

Fig. 1 - Wacom Interface with explanation, Justin Love and Steve Gibson, 2008-09.

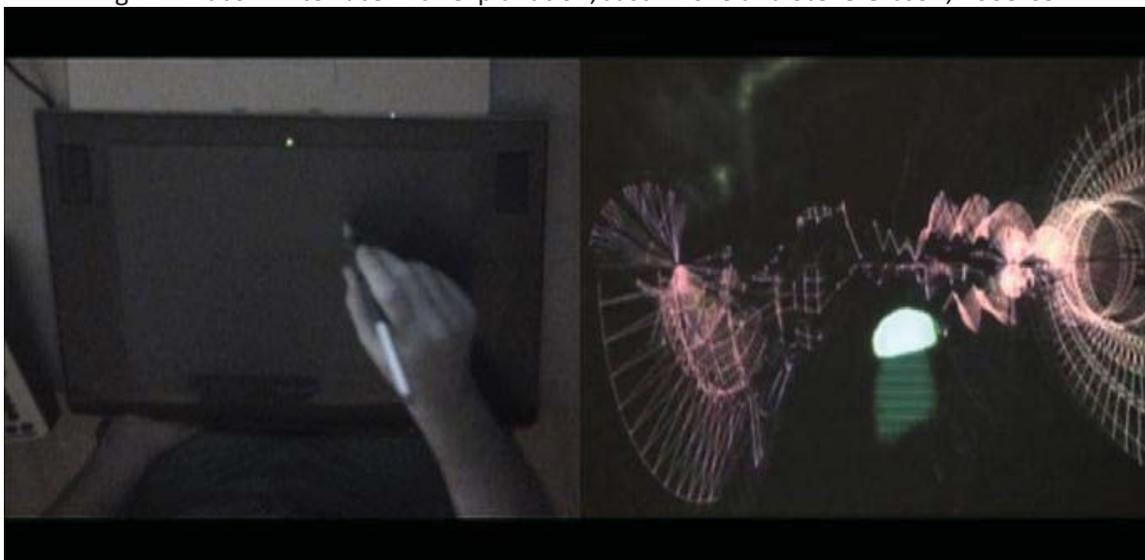

Fig. 2 – Wacom Tablet MIDI Demo. Live performance by Steve Gibson, January 2010. Video by Steve Gibson, 2010.

Introduction

The paper considers the connection between drawing technique and media control both generally and specifically, postulating that dynamic drawing in a live context creates a performance mode not dissimilar to performing on a musical instrument or conducting with a baton. The use of a dynamic and physical real-time media interface re-inserts body actions into live media performance in a compelling manner. Performers can learn to “draw/play” the graphics tablet as a musical and visual “instrument”, creating a new and uniquely idiomatic form of electronic drawing.

Electronic drawing is generally (though not exclusively) limited to pictorial or representational drawing with a pen and graphics tablet in order to produce still images or frames for animations in software such as Adobe Flash. Given the authors’ background in media art, physical computing and transmedia applications, we were more interested in the idea of repurposing the graphics tablet as media control device. We were particularly interested in the act of electronic drawing as a means of manipulating sound and video rather than as an output to an actual drawing, whether on-screen or for print.

Other 3D “tablet-like” devices have been used for manipulating sound, including the popular Kaoss Pad from Korg. [1] These devices are generally very limited in size: the Kaoss Mini KP has the following dimensions: 4.17 in (W) x 5.08 in (D). In the context of live performance this size does not allow for dramatic gesture.

The notion of the dramatic gesture was very important for us since we wanted to use a tablet as the only visible performance element. It was imperative that the audience be able to identify performer gesture with perceptible results in the media used (live sound and video in our case). To achieve this aim a larger area for drawing would be required. Finally, another limitation of other 3D controllers such as the KAOSS pad is that they are ‘only’ 3D. In order to achieve complex control of the media elements through our drawing actions, we wanted to be able to use more than three parameters at a time.

For the above reasons we decided to use a graphics tablet as a control device for gestural performance, and in particular we selected the Intuos 3 from Wacom (now superseded by the Intuos 4. [2] The Intuos 3 is 9 inches x 12 inches in dimension and has five degrees of control. This large surface combined with five possible control parameters made it an ideal choice. Also the fact that one uses a pen with a graphics tablet makes it more useful as a performance instrument, since the pen is a visible object that audience members can identify in much the same way as they would a conductor’s baton (though the audio-visual results we aspired to were quite different from those of an orchestra).

Background: Live music performance as a visual medium

Our interest in repurposing a device such as a graphics tablet for media control stems from the authors’ dissatisfaction with certain modes of electronic music performance. Live music has traditionally been experienced as a partially visual medium, with the visible actions of the performer holding the attention of the listener: “Making music involves not only the communication of musical sounds but is also characterized by a continuously changing and meaningful use of facial expressions, body movements, and hand gestures. Until the late nineteenth century, music performances were almost always experienced as audio-visually integrated activities.” [3]

With the advent of electro-acoustic “tape-based” music in academic electronic music and laptop performance in popular electronic music, the visual reference of the performer became “un-stuck” from the resulting sound produced in a live performance scenario. The relatively long history of tape-based electro-acoustic music has attempted to deal with the lack of performance spectacle by ever-increasing complex “diffusions” of the sound in space. This often involves ever-increasing numbers of speakers placed strategically throughout the room. For example, the BEAST “diffusion” system at Birmingham University has “over 100 discrete channels” of sound available. [4]

When used effectively this can create a sort of architectural soundscape, in which the listener follows the sound around the speakers and thereby intuits an image of sound as an object in space, albeit virtually. For the most part though, it is hard to avoid the conclusion that the use of ever-increasing numbers of speakers is a rather desperate ploy to obfuscate the fact that the audience does not easily respond to music in the absence of the visual spectacle of the performer. In short, in the majority of cases, the tape-music concert is one that generally does not satisfy the audience need for performance complexity. The genuinely live performance event has possibilities for variation, expression, errors, and communication with the listeners/viewers that are lacking in purely tape-based performances.

Similarly, pure laptop-based popular electronic music faces a similar crisis. When the performer is hidden behind the screen, it is simply impossible to recognize or even infer what he or she might be doing. As with tape-based music, the visual aspect in laptop performance is reduced to a virtually-inferred spectacle at best. (It should be said that in laptop performance there is at least the presence of an actual performer, and though it may be difficult to ascertain his or her actions, at least he or she is generally doing ‘something’ live).

The introduction of physically expressive performance aspects into electronic music has increased in the past ten to fifteen years. With improvements in computer speeds and the growing number of gesturally expressive media control devices available, electronic music has become increasingly engaging within a genuine performance context. The laptop is still employed live in most cases, but at least it is being controlled by a performer with some other device that the audience can relate to as an instrument. In this regard the live electronic performance medium (with a physically present and “active” performer) bears some resemblance to the drawing medium, in that deliberate and unconscious gestures in time form a basis for the artist input in both mediums. In both drawing and live performance errors are allowed (or are, at the least, quite inevitable). Meandering, testing, chance, and happy accidents in improvisational or semi-improvisational mediums such as live electronic music or DJing, are quite relatable to doodling, dreaming and sketching in the field of drawing.

Background: The VJ as live performer

It is worth noting that the VJ faces a similar problem to that of the laptop performer: how do his or her actions relate to the music and visual performance and how does the audience perceive those actions as in any way corresponding to the audio-visual results? VJing generally relies heavily on digital signal processing (DSP), in which the VJ software detects aspects of the incoming audio (e.g. hard attack beats coming from a kick drum) and consequently applies effects, cross-fades, or clip edits based on that information. This normally creates an obvious connection between the audio performance and the resulting visual world, at least on the rhythmic level.

While these DSP tools provide a solid automatic connection between the audio and video in a VJ performance, there remains the presence of the VJ performer: as with laptop music performance, in the absence of any noticeable interface beside the laptop, the performer's actions are somewhat mystifying to the audience.

For the above reasons we decided that the graphics tablet served as a potent tool for uniting the DJ (or electronic musician) and the VJ under a single interface. In addition by using the large surface of the tablet as an interaction device we created a dynamic performance instrument that the audience could relate to in a very physical manner.

Initial research

Our initial research into programming options for using MIDI with a Wacom tablet uncovered some pre-made applications, but in general we were unsatisfied with the both the usability and "look and feel" of these solutions. For example, one such application that we considered was the "Tablet 2 MIDI" interface developed by Livelab in Denmark. [5] This program allows complex mapping of MIDI data to multiple parts of the graphics tablet. The essential problem with this model is that it uses a complex menu-driven user-interface that is not intuitive. In addition the application is Windows-only, and given the fact that the authors (and much of the digital media community) are Mac users, we determined that this "off-the-shelf" solution was not ultimately viable. If we wanted a solution that would meet our needs and the needs of a more general digital media community, it would be necessary to develop our own alternative application.

For this reason we decided to look at creating our own interface using Max from Cycling 74. [6] Max has an application programming interface (API) that allows users to create their own external objects. The extensibility and modularity of Max has resulted in a large community of developers that create and share their custom Max external objects. To implement our interface we incorporated a Max external object designed by Olaf Matthes that outputs data produced by the Wacom Tablet. [7] In the Max patch, the data from the Wacom tablet is routed and mapped to a series of user-definable MIDI messages that can then be used to produce audio and video manipulations and transformations.

Interface design

It was essential that the interface that we created be entirely contained in one window, with no need for submenus or even normal file menus. Fig. 1 illustrates our basic interface design. Side-to-side (x), up-and-down (y), pressure (p), tilt x (tx), and tilt y (ty) can each be mapped to any of 127 possible MIDI control change parameters on 16 different MIDI channels. In addition, control curves can be applied to each parameter. For example, a linear control curve produces a consistent rate of change for a given parameter, whereas an exponential control curve causes a parameter to change slowly at first and then increase rapidly towards the end. The MIDI output can be routed to two different MIDI ports simultaneously. The grid at the top allows the user to save up to 96 different MIDI control change setups in one file.

Connecting with audio and video

To connect our application with other MIDI software, we used Interapplication MIDI. This allowed us to instantly map tablet actions to an effect or parameter in the audio or video software. Naturally only five

tablet parameters can be used to control video or audio data at the same time, but it is possible to route the same MIDI control data to multiple functions in the video or audio applications. With the grid of 96 storable configurations, once the user gets tired of the same configuration a new one can be loaded instantaneously. It is possible to cue a configuration (similar to how a DJ would cue a new track) and press one button to immediately activate the new setup.

The applications we use with our tablet audio-visual interaction are Ableton Live (for audio) and Modul8 (for video). Both of these programs are ideal for live audio-visual performance as they have extensive MIDI support and are built for non-linear performance situations in which the user may want to change, modify or apply effects to audio-visual materials instantaneously.

The tablet as a live performance device

With the possibility of seemingly endless mappings of tablet data to corresponding audio and video effects we were acutely aware that some sort of logical mapping structure would have to be established in order to allow the interface to be used effectively in a performance situation. This harkens back to the concern that we had at the outset: we wanted to be sure that tablet actions had observable results so that audience members would be able to clearly identify the relationship between the live drawing and the performed audio-visual elements.

In the past Steve Gibson has worked on several projects which explore 3D interfaces and the connections between audio and video mappings and 3D control. The most important of these projects was *Virtual DJ*, in which the user is given control over an audio environment and lighting effects by moving in 3D space. [8] In short this project used standard control configurations between user actions and results in the audio-visual system. For example, raising the hands would generally play an upwards melody and with each new note a light would change colour. This allowed the user to identify that their motions were having observable and repeatable effects in both the audio and visual realms. In essence this simulated the effects of synaesthesia, a condition in which persons can often see colours in response to particular sounds, tones or musical notes: “Synesthesia is an involuntary joining in which the real information of one sense is accompanied by a perception in another sense.” [9]

For our tablet interactions we thought of the tablet interface as a miniaturised version of the multi-dimensional spatial interface used in *Virtual DJ*. Thus logical interactions could be inferred by testing user actions with system results. For instance, drawing on the y-plane on the tablet (up-down) could logically map to audio volume or low-pass filter (which would have a similar effect to volume, without completely removing the sound at the bottom of the tablet) and image opacity. Therefore we built a limited series of controls to be employed by the user on the tablet and held to these controls throughout our performance. The videos at the following two links show how three of the tablet parameters (x, y and p) were mapped to audio effects:

Conclusions

In summation we have found that the Wacom graphics tablet is a powerful device for controlling live audio and video in a performance situation. The act of live drawing, though here removed from its traditional reference to a produced “drawing” (either on-screen or in print), is one that allows for dramatic gesture in a way that pressing keys on a computer keyboard or moving a mouse could never hope to achieve. In addition the fact that the graphics tablet can unite five degrees of control over live audio and video makes it an ideal tool to consolidate the roles of the DJ and the VJ under one control interface. Finally we present a live example of the tablet used in a performance situation with one of the authors controlling live audio and video with his drawing actions (Fig. 2): http://www.telebody.ws/TRACEY/Tablet_Demo_Split.mov.

The Wacom MIDI software can be downloaded at: <http://www.roguescience.org/files/wacom2MIDI.zip>.

DIGITAL PUBLICS: PROMISES AND PROBLEMS OF A CYBER-REVOLUTION

Philip Glahn

Reconsidering the historical avant-garde's engagement with the "mechanization of experience," organizations like Mikro.fm seek social innovation through digital technology, facilitating a redistribution of the ownership of the means of knowledge production. Looking to Brecht's radio theory, the Berlin-based group engages in a heterotopia of pragmatic collectivism, wary of making the bourgeois public sphere's empty gestures of participation.

Digital Publics: Promises and Problems of a Cyber-Revolution

Reconsidering Sergei Eisenstein's unfinished *Capital* project, German filmmaker Alexander Kluge recently contemplated the abiding potential of cooperative production: "A constellation of corresponding works. That's how Eisenstein's spherical dramaturgy is to be understood. Not a utopia but a heterotopia: right next door something is possible." [1] What sounds vaguely like a nostalgic, rhizomic relativism is in fact a strategic demand for the fulfillment of the historical avant-garde project. Kluge's own films, including his 2008 *Nachrichten aus der ideologischen Antike: Marx – Eisenstein – Das Kapital*, promote "relationality": the notion of the cultural arena as a site of struggle over meaning and visibility, the means of making sense and spreading it around by establishing connections, or "striking sparks," between positions. Emphasizing the use-value of artistic labor and the functionality of its products, Kluge's Eisenstein project aims to make the relationships of production tangible – between the real and the ideal, history and myth, experience and fantasy – to, in Eisenstein's own words, "teach the worker to think dialectically." [2]

For Kluge, the procedures and proceedings of 1920s and '30s radical art imply the very pragmatic possibility of implementing substantial contemporary socio-cultural transformation through art nearly a century later. Indeed, conditions central to the historical avant-garde project no longer seem as antiquated as they did during and even immediately following the Cold War. New networks of information dissemination and economic dependencies, the political and social struggles in the East and Middle East, and the recent crisis of global capitalism have shaken traditional ways of governing people, properties, and worlds to their foundation, giving questions of socialism, technological progress, and class a renewed validity and urgency. New media art and activism in particular has for well over a decade acknowledged, considered, and elaborated on the changes in our socio-technical landscape. As digital forms of information exchange and knowledge-labor blur traditional boundaries of community and identity, "tele-" and "cyber-communism" declare the dawn of a new sociopolitical era that in many ways harks back to that of the historical avant-garde.

New media art and activist organizations sound a strikingly Productivist and Brechtian tone in their avowals to employ digital technology to turn consumers into producers, availing mass participation for social innovation. These groups reprogram GPS devices to map new ways to navigate urban environments, devise open-source software for redrawing eco-political landscapes, and organize festivals and workshops for the collaborative production and broad dissemination of information and technological know-how. As such practices seek to reconstruct the public sphere, the question remains whether the access to information and the technological means of its production actually redistribute ownership of

knowledge, labor, and experience, fomenting real action and agency, or whether such projects further institutionalize an ideal bourgeois public sphere by creating a mere semblance of cultural participation.

The Berlin-based collective mikro.fm provides an example of a contemporary practice seeking to combine and maximize the potential of both old and new media to form evolving and strategically contingent constellations. Like many other new media communications initiatives, mikro.fm provides free, non-commercial public access to online and airwave studios as well as the know-how necessary to fabricate and use portable transmitters. Steeped in the traditional conflict of communicative technologies (the radio apparatus as much as the Web) between the material promise of unregulated, democratic exchange on the one hand and its populist and private appropriation on the other, mikro.fm holds workshops and gives presentations, circulating ideas and instructions via airwaves and the Internet advocating the portable transmitters as a way to produce, receive, and pass on stories and news, fantasies and perspectives excluded from or marginalized in the mainstream media.

If indeed, as some have observed, today's socio-economic and psychological climate recalls that of the Weimar Republic and its "experience of mechanization," a critical look at the medium of radio at its moment of original popularity, at the historic crossroads between barbaric instrumentalization and emancipatory utility, proves instructive in contemporary debates about the revolutionary function of new media art and activism. Regarding its own heterotopia of direct, proximate usefulness through the active everyday production and dissemination of broadcast programs, mikro.fm has looked to Bertolt Brecht's "Radiotheorie." [3] Like culture in general and theater and film in particular, to Brecht the radio has no value in and of itself but is defined entirely by its use. In the hands of the bourgeoisie, according to Brecht, the radio is anything but a "mass medium": delivering "Viennese waltzes and cooking recipes," pseudo-debates and purely commercial art, it has, in a reversal of the potential function of the broadcast apparatus, an individualizing and inactivating effect on its audience. [4] In this case a new medium is used paradoxically to reproduce old contents, habits, and relations.

In his 1932 essay "The Radio as an Apparatus of Communication," Brecht famously remarked that "the radio is one-sided where it should be two," advocating the ability to literally talk back, to discuss via the apparatus of transmission. [5] Perhaps more importantly, Brecht's call for material as well as ideological innovation through the transformation of the radio demands that what is being communicated must have relevance to the audience and engage the listener as a speaker. The objective is to turn the audience "not only into pupils but into teachers." [6] Accordingly, "re-transmission" is as important to mikro.fm as the distribution of original content. Listeners are encouraged to engage with themes like nuclear power and the census, anti-Semitism and "medial creativity," navigating and contending with a multiplicity of official narratives, alternative concepts, and personal experiences. Topics are discussed in contexts ranging from the general to the local, the historical to the present-day. The soldering workshops connect technical labor with the anticipated intellectual and social labor of using the apparatus as a communicative device, fostering an awareness of the way in which the skill of "making" functions on several levels. It furthermore imparts a sense of sober functionality over techno-euphoric spectacle. The utility of the self-made transmitters, as well as the collective's recent "editorial" work with the Berlin station "PI Radio" (the PI standing for "pilots" or "pioneer"), is part of their effort to counter "anonymous media consumption" by producing and promoting online networks and "radio clouds," echoing Brecht's idea of the radio as "a network of pipes" that "turns listeners into suppliers." [7] True innovation means to go beyond participation as a gesture and turn it into an action of agency.

As with the Eisensteinian constellation, the relationality afforded by mikro.fm's projects is not restricted to the technological dimension of accessibility. To strike sparks between positions does not suggest to

merely plug into the apparatus, but rather to establish an exchange between different modes of production – of experiences, ideas, identities – to acknowledge the public sphere as an arena where one’s position as spectator and producer stands in critical proximity to the institutions of information distribution and their discursive regulations. The redistribution of ownership demands that for cooperative production to be truly cooperative, it needs to impart the ability to participate in an evolving project of knowledge production (rather than reproduction), to articulate existing dependencies, limits, and possibilities. New media establishes proletarian public spheres where, as Brecht observed, the material and technical abilities to say anything to anybody are used to transform rather than maintain the existing social order, by “putting the listener into relation rather than isolating him.” [8]

SYNTHETIC PHYSICS: IDEAS FOR NEW WORLDS

STEFAN GLASAUER

While the physical laws of our real universe cannot be modified, in virtual computer-generated worlds arbitrary physical laws can be implemented. However, critical constraints of synthesizing such physical laws are given by our sensorimotor system and by the consistency of the resulting virtual world. It is proposed that synthetic physics has an enormous potential not only for education but also for creating art using physical laws as medium.

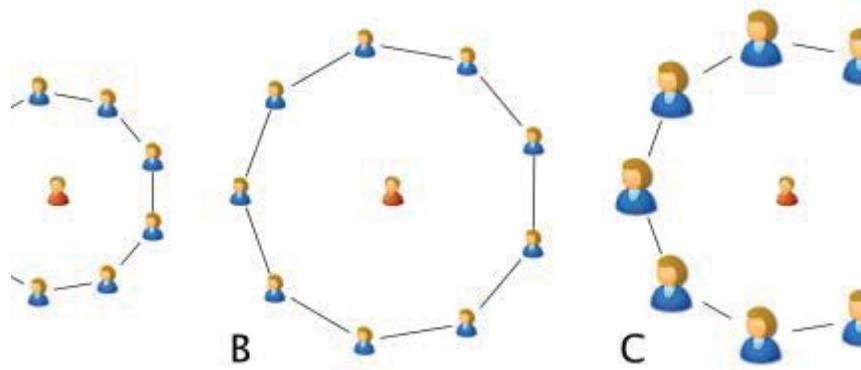

Figure 1: Example for the violation of consistency. A: initial situation: persons at a constant distance form a circle around the viewer. B: each person steps back so that their interpersonal distance increases and they can no longer touch each other. C: for the viewer in the center, the visual angle increases due to the Turtur-effect (see text), which means that the apparent distance between the persons seems to decrease: touching each other seems possible, while physically it is not.

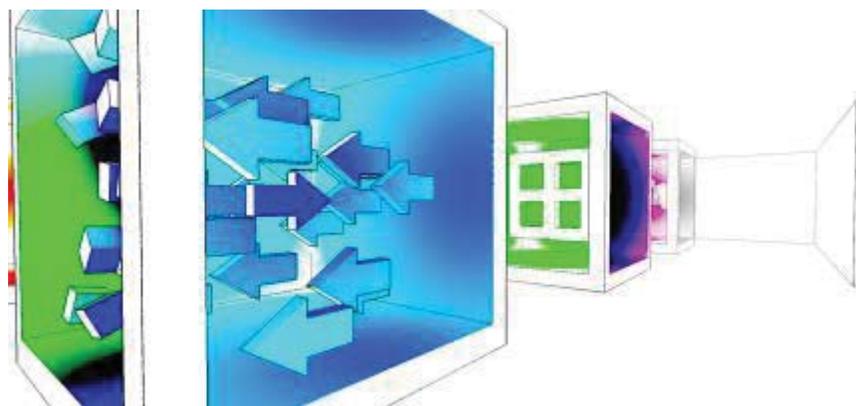

Figure 2: The computer game *Antichamber* [11], which claims to abandon Euclidean geometry (screenshot courtesy Alexander Bruce).

Introduction

When we enter one of the many virtual worlds available nowadays, be it a simple flat world represented in a browser game or a sophisticated three-dimensional world in a high-end computer game, we usually expect that most of the basic rules of every-day physics and geometry in the real world are implemented also in the virtual counterpart. The geometry is Euclidean, objects look smaller when farther away, there's an up and down, and if things fall, they fall down. Sometimes we can fly in a virtual world, sometimes things do not cast shadows, but in principle all the rules are a simplification of the real-world physical laws. But is that really necessary? Can't we go "beyond physics"? [1]

In the following, these rules or laws will for simplicity be called 'synthetic physics' – denoting not only the basic underlying rules of how objects and agents should physically interact with each other and the simulations performed by the so-called physics engine in game engineering, but also more generally all rules concerned with physics such as the topology of the simulated space or the laws of synthetic optics. So far, the designers of multi-user virtual worlds seem to have adopted the simplistic approach of taking the physical laws of reality, simplify, and use the result as blueprint for synthetic physics. But already in the mid-90s Michael Benedikt suggested that the space of possibilities allows for more. [2] After providing examples of 'impossible' physics - most of which are actually dealing with spatial topology rather than physics in the real-world sense - he proposed several principles meant to serve as guidelines for the successful design of cyberspace.

Real physics

Before discussing these design principles, we need to take a closer look on the real physical laws and the simplifications made by metaverse designers. Take any physics textbook, and you will immediately realize that not all physical laws are relevant for our experience of the world. Special relativity does not have any impact on our daily life, and we need not be aware of quantum physics to catch a ball. In fact, we do not even need to know about Newtonian physics; mankind did well without explicitly knowing about it for most of its history. However, when trying to design a considerably convincing replica of the real world, it becomes important to consider which physical laws should be implemented. To date, the sensorimotor constraints in interacting with a virtual world are provided by the interface technology. The main sensory input supplied by multi-user virtual worlds is vision and audition, the latter often playing a subordinate role. Consequently, the main effort in implementing real-world physics goes into providing a decent graphics engine, realistic sound sources, and rigid body dynamics. Other aspects of real-life physics such as fluid dynamics are usually omitted. Evidently, some omissions affect the amount of realism, whereas others do not, such as restricting the simulation of electromagnetic radiation to the visible spectrum rather than implementing, e.g., radio wavelengths. The simplifications lead to unreal – or hyper-real – [3] physical environments, which can provide an unexpected educational potential: virtual physics invite to experiment with physical laws rather than just simulating real physics. [3]

Psychophysics

Nonetheless, with the user being the central element of any virtual world, the implementation of physical rules needs to be adapted to the capabilities of the users. Here it is where psychophysics come into play: neuroscience, rapidly advancing during the past decades, and experimental psychology, building on

the psychophysical foundations laid out in the past century, tells us how perception works, how experiences are generated, how we react to changes in the world, and how we interact with the world and its objects. One of the most important insights is that we do not directly sense the physical properties of objects, but estimate them based on multisensory input and prior experience, which may be innate or acquired over time by learning. Our perception is thus an indirect estimation process rather than an accurate measurement of object properties. Besides relying on sensory information, the perceptual estimation processes are based on general assumptions about the world. Perhaps the most important one is the assumption of constancy (color constancy, size constancy, etc.). These constancy constraints or invariances, reflecting the statistics of the environment in which we live, are assumed by many researchers to be the basis for our perception. Our actions are shaped by knowledge about the statistical properties of the world and thus we implicitly assume that the statistics of the world do not change rapidly. We thus may formulate, following Benedikt, [2] a 'Principle of Constancy' for the design of virtual physics to meet the abilities of our human perceptual and motor systems.

But which of the properties of the real world need to be preserved in a virtual world for humans to be able to interact with it? In our opinion, some of the a-priori assumptions of everyday sensorimotor processing, such as the existence of gravity, need not to be implemented and can be ignored without significantly affecting action and perception within virtual environments. But we seem to be able to deal with much more drastic alterations: a recent study claims convincingly that humans, given extensive training, are able to efficiently navigate a four-dimensional maze-world. [4] Thus, we apparently can adapt to properties of a virtual environment that most of us consider as being completely unimaginable. Another study investigated how humans behave in physically impossible environments and whether they consciously notice the violations of Euclidean metrics or planar topology. [5] The surprising and conceptually far-reaching finding is: you do not realize it. And you behave just like in a normal virtual environment that mirrors the metrical and topological properties of the real world. Thus, in contrast to Kantian ideas, a-priori properties of space such as Euclidean geometry do not seem to be required for spatial behavior.

Alternative physics

Can we thus conceive of alternative physics, which, nonetheless, allow for interaction with content, be it user-created or supplied by the virtual world, and with other users? We think that it is possible to create virtual worlds with such alternative physics without completely disorienting the users. It could even be possible to have different physics within a single virtual world, allowing the user to change certain physical parameters, properties, or even rules within a given, carefully selected set of meta-rules. This set of meta-rules needs yet to be defined, and an interdisciplinary approach of physics, mathematics, and cognitive science will be required to do so. Creativity paired with analytical capabilities and profound knowledge is asked for to design such a rule set with its most important ingredient being consistency.

Let us take an example from fiction to illustrate what consistency means. Michael Ende describes in his novel for children "Jim Button and Luke the Engine Driver" a character called Mr. Turtur. [6] Mr. Turtur is a pseudo-giant: he appears to be a giant when viewed from far away, but when you approach him, he seems to shrink and finally is just as tall as any other human being. This character works well within the novel, but would not be consistent as alternative physical possibility, since, for example, a normal person standing next to him and holding his hand would become inconsistent: either the arm of Mr. Turtur or that of the person holding it would need to be distorted to not appear to lose contact. One possible

solution seems to be that everything should grow in apparent size with increasing distance. But this solution would again violate consistency: imagine looking at a circle of people holding each other's hand around you. The circle is quite close to you (Figure 1A). If each person steps back a certain distance, they lose each other's hands, because the circle grows (Figure 1B) and the interpersonal distance increases. But for you it would *look* as if they could still hold their hands, since their apparent size grows (Figure 1C). Your view and the physical facts are thus no longer consistent, not to speak of how persons in the circle would appear to each other.

Note, however, that the notion of consistency does not contradict the finding that Euclidean geometry is not important to solve spatial tasks. [5] Even though it may seem as if a triangle with three 90° angles is inconsistent, it is, in fact, not inconsistent in itself but just with Euclidean geometry. Thus, in a different geometry, which is not physically possible in our world, the triangle can have three right angles.

The potentially beneficial use of breaking specific real-world assumptions for the design of interaction techniques has been investigated by Pierce & Pausch. [7] In their example, landmarks such as towers used to navigate over intermediate distances do not completely vanish with distance but remain at a minimum size. While this proposal, which clearly reminds of Mr. Turtur, breaks the continuity of space (the landmarks 'grow' relative to their surrounds), it can help users to navigate in an environment by serving as virtual beacon.

As Benedikt [2] points out, art and fiction have described many possible alternative worlds and the boundaries for the fantastic seem to be stretched as far as possible. We need not even go as far as theoretical physics, where exploring alternative worlds based on different laws is a serious branch of cosmology. Thought experiments of alternate worlds also have a long tradition in philosophy, e.g., Hilary Putnam's famous Twin Earth. However, these thought experiments or the many fantastical scenarios in fiction and art never left the stage of verbal description or depiction. Now the time is ripe to implement them in virtual worlds to be able to experience what it would mean to inhabit such a world and act within. The most recent examples giving us a clue of what might be possible are science-fiction movies such as "Inception" (written and directed by Christopher Nolan, 2010), in which 'virtual' worlds are created in order to serve as backdrop for dreams.

However, so far only very few developers of virtual worlds seem to go as far as abandoning Euclidean geometry: apart from the authors of the scientific study mentioned above, [5] Alexander Bruce is one of them. He is the developer of the yet to be released computer game Antichamber [8] that, according to his website, aims to be a "Philosophical First Person Single Player Exploration Puzzle Art Game" (Figure 2).

Physics as concept

From an artist's point of view, the whole story is completely different. Just as the potential of virtual worlds for scientific research has been emphasized repeatedly, there is an equally large potential for artistic discourse. But just as any other artwork, art using virtual worlds does not need to respect any boundaries, principles, or rules, and may even be more potent when those boundaries are violated. There are many examples in art history, specifically in the last century, where breaking the boundaries was an inherent element to successful artwork. To avoid misunderstandings: artists have, probably with few exceptions, never respected the laws of physics in their work. But that is not the point. Rather,

artists so far could hardly use physics, and here we mean the physical laws and constants, as a *changeable medium* of their work, because they did not have the possibility to modify anything about it. Even though artists such as the sculptor Richard Serra or the installation artist James Turrell may count as an exception in their explicit treatment of physical topics such as gravity, balance, and light, it only is now that an artist could design a new system of physics, be it consistent or not, and have visitors come and feel what it means to be inside such a world. The approach may be compared to 'environments' [9] in installation art or participatory performance art. This interaction between the work and the viewer, while present in all works of art, has a specific immersive quality in such environments, which effectively resembles the non-verbal dialogue between artist and viewer in performance art, especially if it demands participation. In both the installations and the performances, the visitor is not just viewer but active participant experiencing the real emotion rather than just being confronted with its representation. Consequently, work such as the 'participatory objects' of Robert Morris (Tate Gallery, 1971) explicitly form an environment in which the visitor becomes the actor of a performance. The same holds for visitors of virtual worlds: as soon as they enter and interact, they become part of the work and as such performers within an environment.

If we understand the physical laws as instructions underlying the universe, then we can see *physics as concept* in the sense of conceptual art. One of the most influential texts on conceptual art [10] explains that "The idea becomes a machine that makes the art." Physics is the idea that makes the universe. And if the physical law was an artist's idea, the resulting universe is art.

DRIFTING AND IMAGING BEIJING

Maayan Glaser-Koren

Is John Craig Freeman's "Imaging Beijing" a contemporary expression of the Guy Debord's *dérive* theory, made possible in Second Life?

Freeman's overall project and its individual components such as "Imaging Beijing" are analyzed here through Jean Baudrillard's book *Simulacra and Simulations* (1981), and particularly his notion of the simulation.

In John Craig Freeman's Imaging Beijing, Second Life Installation, © 2008 Maayan Glaser-Koren

While discussing the contemporary American artist John Craig Freeman's *Imaging Beijing* I will evaluate how Guy Debord's notion of the *dérive* is applied to the internet environment while also discussing the ways in which Freeman's work challenges, tests, or confirms the *dérive* as a theory, followed by a discussion of its relevance today. Freeman's piece *Imaging Place* is an ongoing site specific artwork combining photography, video, documentary, 3D software, and virtual reality. The original project started in 1997 when Freeman began to document the locations he visited. Every location was documented and then installed into Second Life in 2006 [1]. These locations are depicted as a platform that merges satellite images of a specific site in the city, panoramic photography, and digital video. *Imaging Places* assembles different places in the world such as *Imaging Wall Street*, *Imaging Belfast*, and *Imaging Beijing*. Freeman's complete project and its individual components, such as *Imaging Beijing* (2007) can be analyzed through Guy Debord's *dérive*

Debord's theory of the *dérive* (1960s) refers to drifting throughout the city (Paris) in a rapid manner without planning ahead. The result is awareness of the environment and the surroundings. The subjects must separate themselves from the activities of daily life and especially from the media for this to be successful. Debord, writing in an era characterized by the soaring popularity of television and the wild proliferation of commercial media and advertising, noted that society itself was being transformed by technology. His *Society of the Spectacle* (1967) describes the emergence of a consumer society and proclaims that the spectacle that is mass media dehumanizes the Western world. Debord's proposed solution was the *dérive*, which was to arouse in subjects an increased interest in the geography of the city.

Debord claims that "in a *dérive* one or more persons during a certain period drop their relations, their work and leisure activities, and all their other usual motives for movement and action, and let themselves be drawn by the attractions of the terrain and the encounters they find there." [i] More compellingly, the *dérive* was to create new encounters between people and places that were not otherwise possible and through this allow for positive social change. The intent of the Situationist International Project and its leader, Debord, was to change the confined society of which it was a part [2]. Their goal was to battle against media saturation, boredom, and the capitalist co-option of life. The *dérive* was a situation the project constructed to disrupt social spaces.

John Craig Freeman's artworks emphasize the notion that in our Western contemporary society we are still influenced by the media and therefore do not pay attention to our surroundings. He claims that he uses the *dérive* because "it is a subversive act which calls into question the constructed social order of the city. It is my intention to do the same in the social spaces of the Internet." [ii] Is the experience of the *dérive* the same in the virtual world as in the Situationist's European city? In order to answer this question, I will examine if Freeman's claim is possible throughout the use of Second Life.

In Freeman's *dérive*, which is performed throughout the use of the virtual world, participants encounter his work through an avatar that takes the role of the *dérive*'s psychogeographer. This allows for a new awareness of the terrain. For example, in *Imaging Beijing*, one's avatar enters the city through satellite images and experiences it through panoramic documentary photographs. *In Imaging Beijing, the avatar's dérive starts from a satellite image of the disc of the earth. On earth there are rotating enter signs that indicate the cities on the map to which the avatar can teleport.*

China's capital city, Beijing, is represented by a satellite photograph from a Google map showing central Beijing and translated into virtual reality. On this platform are sixteen spheres, inside of which are panoramic photographs taken by Freeman during an actual visit to Beijing. On the platform are four each of red dates and paths connecting the spheres to the platform that indicate a location on the grid. Clicking any of the dates opens a blog, which includes Freeman's real-life documentation, stories, and photographs from the day he experienced in Beijing.

The idea that Beijing is represented by Google satellite image relates to Debord's notion of the spectacle. The spectacle can be the mass media, the consumer society, commodities, the consumption of images, spectacles, or contemporary capitalism and its effect on modern society. Therefore today's technology, for example, Internet Web sites, satellite images, and virtual worlds, are part of the spectacle. However, if *Imaging Beijing* is a spectacle, then how can it be a subversive art piece? In the essay *Debord and the Postmodern Turn: New Stages of the Spectacle* (1997), Best and Kellner suggest that virtual reality, computers, and multimedia are the new stages of the spectacle. They propose that there are two kinds of spectacle: an interactive spectacle and a pseudo spectacle. The first "is one that the individual herself has created." [iii] It can be one's Web site and chat room. The latter is created by "corporate

forces that themselves construct the spectacle in which one is merely a part," [iv] for example, television shows and radio talk shows that can monitor and control an individual's participation. Consequently, Freeman's *Imaging Beijing* is an interactive spectacle because it was created by an individual and is limited to the participants' experience.

The notion is that *Imaging Beijing*, as an interactive spectacle, is enhanced by narrations from a Beijing resident, Peter Guo. When an avatar stands in the center of each sphere, the audio narrative begins with Guo discussing his memories and childhood anecdotes from his life in Beijing. In a way, this is a point in virtual space where cyberspace, the real world, and the virtual world become one. For example, entering into these spheres provides one the experience of using a first perspective view of the actual location - a panoramic photograph, providing the sensation of being part of that location. Then, the experience is enhanced by real sounds such as Guo's voice, and the environmental sounds, contained in the audio clips. Moreover, Guo narrates the story in English and then in Mandarin. All of this creates a realistic sensation, a sense of knowing Beijing, its residents, and its atmosphere without physically being there, which results in a simulated *dérive*.

The *dérive* is a way to inhabit space. According to the Situationist International, the best place to perform the *dérive* is in an urban space. Participants in the *dérive* separate themselves from their daily activities such as jobs, media and leisure and are drawn out by the attractions and encounters in the city. Additionally, the more people who participate in the *dérive* as a group, the more likely they will conclude that the experience was rich. In addition, the *dérive* holds the idea of the psychogeography.

Debord's notion of psychogeography attempts to create a new awareness of the modern city and the urban landscape. According to Debord, it is a detailed study of how specific geographical environments affect the emotions and the behaviors of individuals.

Freeman's work interrogates Debord's notion of psychogeography and the *dérive* within new cyberspaces. *Imaging Beijing*, according to Freeman, expands the concept of the *dérive* on two different levels. He states: "There is the level that occurs in the field on location, such as in the Hutongs of Beijing. I am testing whether immersive media is capable of capturing and representing the experience of the urban drift and the resulting emergent situation. So there is a quasi-documentary side of the work." [v]

The second level, which extends the notion of the *dérive*, according to Freeman, is "at the delivery of the work as a new form, whether it is online or in an exhibition. This puts the avatar or audience in the role of the psychogeographer drifting through the virtual world. It is still an image, but one that you can navigate, explore, have adventures and social interactions in." [vi] In other words, the avatar navigates by walking into the spheres. Each sphere is different and includes different audio narratives by Guo. In addition, the sounds that surround him in the Hutong neighborhood enhance the sense of the exploration and adventure to navigate the spheres.

Exploration and navigation are part of the *dérive* that occur in Freeman's work as well as with the Situationist International. Furthermore, there are more similarities between the theory of the *dérive* and *Imaging Beijing* that Freeman applies to his work. First, the subject of both the *dérive* and *Imaging Beijing* is the modern city. Second, in both *dérive*, the navigation starts in a specific place, be it a street in Paris or the Earth disk in *Imaging Place*.

Finally, the *dérive* deals with chances of social engagements, unique conversations, and new relationships. When one drifts through a city, one encounters a large number of people, and therefore there are many possible encounters. The same happens in Second Life, where other avatars access the same place simultaneously. The virtual world allows people from all over the world to connect through the form of their avatars. The unfamiliar creates the opportunity to develop new relationships that will start with a chat. Furthermore, Freeman encourages the use of more than one avatar. This is because avatars can share their online experiences with other avatars they meet and add comments on his work. The same is true for the *dérive*, the more participants, the more objective the conclusion.

According to Freeman, "Like all good *dérive*, one must be willing to become lost." [vii] In *Imaging Beijing*, there is a feeling of losing one's sense of awareness, especially when entering the spheres. The avatar merges into a panoramic photograph of a real location in central Beijing. Thus, as the avatar merges with the location and the surroundings, a sense of true direction is lost. Moreover, because of the fusion between the avatar and the photograph, there is a sensation of mixed realities. The panoramic photographs, the sounds, and the audio narrative are real. The mix takes place when the avatar merges with those elements. Thus the lines between the realistic and the photographed landscapes are blurred. It becomes, according to the American philosopher Richard Kearny, a *pseudo-world* where "the line between the imaginary and the real has been abolished." [viii] This elimination of the boundaries among the real and the imaginary result in a simulated experience.

The simulation is a term that the contemporary theorist Jean Baudrillard discusses in his book *Simulacra and Simulation* (1981). Baudrillard claims that modern values can no longer be applied to current society and are considered dead. The existence of simulation, implosion, and hyperreality are the inability of the consciousness to distinguish between reality and fiction [ix]. This is partially due to the virtual world's ability to blur the lines between the two. Thus hyperreality also relates to simulation, which is the process of replacing real with virtual. By using virtual reality according to the theorist Sherry Turkle, we "blur the boundaries between self and game, self and role, self and simulation." [x]

Simulation is the reason why *Imaging Beijing* does not translate to the real experience of drifting in urban space. However, Freeman is not trying to do so. He simply investigates whether the *dérive* is possible in Second Life. *Imaging Beijing* is a semi-simulation of Freeman's real *dérive*, made specifically to install in Second Life. Thus the avatar only experiences one view of the urban city, as it appears in the eye of the artist creating the virtual installation.

To conclude, Freeman has already acknowledged in his project *Imaging Places* that he is inspired by the ideas of the *dérive*. He is not trying to replicate the *dérive*, but he uses the geography in such a way as to develop "new practices for the Internet." [xi] He has succeeded in bringing the technique of the psychogeography into Second Life with *Imaging Beijing*. The avatar is a psychogeographer, drifting through the satellite images of Beijing, and it experiences the Hutong neighborhood by entering into and merging with the panoramic photographs contained therein.

However, the navigation—the drift—is done by sitting at home in front of the screen. There are no real dangers that one encounters in a real *dérive*; the avatar cannot be injured by walking on the virtual platform. This is different from Debord's notion of the *dérive* where risks are part of the drift in the modern city. Because there is no risk, sitting in front of the screen makes the participant a spectator, which is the opposite to the intent of the *dérive*. The participant using his avatar is not getting out of the house and being drawn to the city's possibilities.

Furthermore, he is being seduced by the interactive simulation and is therefore engaged in a new stage of the spectacle. Then again, the avatar still navigates through virtual space. It is a mix of spectator and navigator. Could this be the next step in the evolution of the *dérive*? Does this suggest that the spectator/navigator must participate in a particular way in order to have a more random encounter, and thus a “*dérive*”? And if so, does this work reflect back on Debord’s original theory of the *dérive*, suggesting that in the city, as well, the spectator/navigator has a degree of agency and responsibility? These questions are difficult to answer because in some ways *Imaging Beijing* is a spectacle.

RANDOM WAR: WHEN ART SPEAKS THROUGH SOCIAL MEDIA

JANICE M. GLOWSKI

Social media is not art, but in the hands of artist Charles A. Csuri and gaming programmers Devin Moore and Wesley Adams, it has become the next playground for a 'Happening.'

A young woman sits at her computer. The archaic sound of a telegraph machine clicks rhythmically, while the names of her friends and family neatly appear across the top of the screen. The synchronized sound and words contrast with the random flashes of red and black 'army men,' who appear in a dizzying and constantly changing array below the letters. She has entered an artist's game called *Random War* (2011).

In Kaprow-esque fashion, artist Charles A. Csuri has placed his renowned work *Random War* (1967) in the hands of people using Facebook, one of the most popular social networking sites of our day. The online version of *Random War* (2011) takes its conceptual cues from the original *Random War* (1967), which used a random number generator to determine which of Csuri's colleagues, friends or a number of famous people, would be slated to one of five categories: "Dead," "Wounded," "Missing," "Survived," or "Medals Awarded." In the original work, the names that Csuri typed into the mainframe computer appear in neat columns in the upper register, each individual assigned a serial number by the machine. Below these outcomes, red and black color-coded soldiers, based on Csuri's drawing of the iconic 'little green army man,' are randomly cast onto a battlefield. They appear tossed about, as if floating in the minimalist, white ground plane. Their haphazard arrangement in the vacuous landscape contrasts effectively with their purposeful stance. People viewing the original *Random War* would recognize many of the soldiers' names; including Gerald Ford, Roy Lichtenstein, and Ronald Reagan; but, unlike Csuri, who directly experienced *Random War's* creation and random process when the mainframe computer printed the results in 1967, they would be left to interpret the results as a static art object.

Random War (2011) realizes Csuri's original 1967 intention — that people experience art as a real-time virtual event. He sought technology that could create a meaningful art object, which personalized the consequences of war. Csuri created a number of *Real Time Art Objects* between 1970 and 1974, many of which pushed the boundaries of art and technology and were funded by the National Science Foundation. However, his vision of *Random War* (1967) as an interactive art object is only being realized as he celebrates his 89th birthday. Using gaming software, Devin Moore and Wesley Adams have written a program that accesses any Facebook Friends' database. Moore and Adams stay true to the original work's aesthetic, carefully preserving *Random War's* (1967) forms and structures. They made raster copies of Csuri's 'army man' (originally rendered as a vector drawing) and tediously duplicated the original machine code-like font.

The online *Random War* (2011) is a thoughtfully made and skillfully programmed animated work that brings *Random War* (1967) to life. It is a dynamic unfolding that feels archaic and cutting-edge, timeless and immediate. It engages and creates suspense without gimmicks and gadgets. Most importantly, in front of a young woman sitting at her computer, it feels personal.

Charles A. Csuri is a traditionally trained artist who taught painting and drawing as a Professor at The Ohio State University for over twenty years. In his early forties, he began making art with a mainframe

computer and punch cards, launching a more than forty-year career as a computer artist. Today, Csuri is recognized as one of the most pioneering computer artists in the world, receiving the prestigious SIGGRAPH “Lifetime Achievement Award” in August 2011.

STRUCTURING SOMNOLENCE: SLEEP SCIENCE TECHNOLOGY AS A MEDIUM FOR DRAWING WITH THE BODY AT REST

Lisa Carrie Goldberg

In December 2010, three volunteers participated in a two-week sleep study conducted by artist Lisa Carrie Goldberg and administered by a certified sleep technician. It was through these nocturnal events that the process of employing the body and the mind during sleep as a means of art making was realised. This paper, therefore, will investigate the fields of sleep science and art.

INTRODUCTION

At present, there is no universally acknowledged definition of sleep. While the science of sleep remains nebulous, now is a time rich with possibilities for artistic intervention and interpretation. According to William C. Dement, a forefather of medical sleep science, the modern incarnation of the field was aided by advances in sleep science technologies and the availability of imaging tools to visualise the brain. [1] Through this advancement in technology, sleep appears more tangible, or at least more visible and more measurable, to researchers. Yet at present, while the production of technological devices is ever increasing, there still exists no unified definition of this corporeal state. In the Structuring Somnolence project, I was not concerned with categorising or labelling sleep. Rather, my investigation is a striving for the comprehension of sleep through various modes of observation and my interest lies in looking at how sleep is being perceived by science today.

The Structuring Somnolence project is an investigation into the points of intersection and commonalities between the fields of sleep science and art, drawing particular attention to the semantic and diagrammatic parallels between sleep science, art, architecture and infographics. Over two years of research, I have seen how aspects of contemporary sleep science warrant highlighting and probing. These aspects pertain to the sleep science's strong reliance on technology and quantification as a means of visualising 'truth' or 'optimum health' or 'disorder' in the endeavour to understand the phenomenon of sleep. A component of this research consisted of a performance event wherein three participants slept over in a sleep laboratory. This act helped to demystify the nocturnal facility by introducing foreign media and 'healthy,' 'non-disordered' sleepers into the space.

SLEEP AS REPRESENTED THROUGH SCIENCE

The study of sleep is a learned language. In its contemporary form, it is composed of an alphabet that can only be acquired and deciphered by an acutely trained eye. Therefore sleep is also an exclusive language. [2] The graphical interpretation of sleep seems to have become the sine qua non for professionals working in sleep research, linking symptom and diagnosis. It remains, at its core, a human-made device that may or may not completely and faithfully reflect the workings of sleep, much less its essence. Without the materialisation of an image either to prove or disprove medical predictions, technologists and clinicians would be hard pressed to find solutions for 'sleep-related issues' with any certitude.

The application of lines as inscription identifiers for sleep research has undergone many incarnations, with each technological development adding to the visual dictionary of sleep throughout history. In its

scientific qualification, sleep is given a written language consisting of a variety of expressive line drawings ranging in thickness, shape and colour – each feature corresponding algorithmically to a physiological process. This contrasts with painterly depictions of sleep, traditionally represented in the fine arts as a scene from a nightmare or as a body lying tranquilly supine, eyes shut and no movement.

In the sleep laboratory, when a patient makes a claim concerning a condition relating to his/her sleep, the claim may only become valid once a data image is produced. The lines in a sleep graph wield tremendous amounts of scientific credence. These lines represent the health of the subject as it pertains to sleep. There appears to be an almost unquestioning reliance on, and trust in, the machine. One aim of the Structuring Somnolence project was to debunk this notion. By constructing drawings with the body using sleep science technology, I bring about a rupture with its normal purpose and highlight the possibility that the computer or 'inscription device' [3] can lie; even when it seems to be all that meets the eye. Theorist Don Ihde makes reference to imaging technologies as 'truth-telling' devices, stating that they "carry this 'eyewitness' quality" and an "aura of seeing-believability." [4] This reliance on visualisations through a "framed space" [5] or "technological mediations," [6] reduces sleep research to an almost monosensory approach.

SLEEP AS A VISUAL LANGUAGE

The imagery and text in the Structuring Somnolence project play with semantic and diagrammatic appropriations across various disciplines. I am interested in the juncture at which seemingly opposite fields meet. The term 'sleep architecture' is commonly used by sleep researchers and technologists to describe a patient's period of sleep. Visually similar to that of a natural or built landscape, it reflects the stages of sleep and awakenings that take place across the night of a study. In the 1980s, Alexander A. Borbély depicted sleep patterns as diagrams, presenting the stages of sleep as the "Sleep Staircase" and REM as Doric columns. [7] Body positioning, as recorded in sleep also produces images that resembles structural landscapes. With this notion in mind, I felt compelled to explore the possibility that the science of sleep is malleable both in its definition and in the application of its designated technologies.

STRUCTURING SOMNOLENCE

In December 2010, I conducted a two-week performance study in collaboration with both SymbioticA, the art-science research laboratory and the Centre for Sleep Science at The University of Western Australia. I was aided by Stuart King, manager of the sleep centre, who was also the head technician for the entire series of performances.

As part of the experiment, three participant sleepers selected a copy of one architectural/landscape image that appealed to him or her in a significant way. Throughout the development of the project, the participants were made aware that together we were attempting to mirror this image through their body positioning in sleep. From the onset, it was explained to the participants, that this project was not about 'sleep hygiene,' sleep efficiency or even a good night's rest. In fact, I would be interfering with their sleep.

The participants were chosen based on their interest in sleep as well a confirmation that they had never been inside a sleep laboratory and had no identified sleep disorders. These volunteers were given the

rare opportunity to see documentation of their sleep in addition to having access into the inner, nocturnal workings of a sleep laboratory. For me, as the lead researcher and conductor of the studies, I was interested in finding participants who wanted to share in exploring and embracing the strangeness of sleep.

Each participant was required to sleepover in the laboratory over two nights. For their first night, the control experiment, the participants took part in a basic, standardised sleep study. This served not only as a baseline study for the entire experiment but also as an aid in familiarising the participant with the laboratory environment and protocol.

The second night, the Somnolence Structuring, involved my intervening with participants throughout the night. It was my responsibility to place the participant's body in a set positions that mimicked their chosen architectural/landscape image. The aim of this animation was two-fold. It was to have the participant's chosen image mirrored in the body position graph depicted within the computer software, which is conventionally used for measurement and diagnosis. At the same time, it would call upon the notion of sleep as an 'active state.' In addition, it would play upon the term 'sleep architecture' through architectural forms built by the body. The Contour Diagram was employed as a draft or map, which was used throughout the studies. It was a booklet comprising a series of structure outlines or contours superimposed on the participant's chosen image. I then plotted the timescale of the entire study, approximately 11:30 pm to 6:00 am, against their chosen image. This booklet was used as the template directing the repositioning of bodies through the night.

Once the participant was in his or her allocated room, electrodes were set in various positions on the body along with the sensor, which was placed on the chest. The electrodes indicated when the participants were asleep and their stage of sleep throughout the night. These sleep indicators included: Electroencephalogram (EEG) for brain waves, Electromyogram (EMG) for chin muscle movement and Electrooculogram (EOG) for eye movements. An Electrocardiogram (ECG) as a heart monitor and a Transducer belt as a breathing monitor were employed as a safety precaution. A body sensor, which was fastened to the Transducer belt that sat around the chest, was responsible for collecting data on the participant's various body positions during sleep. The sensor captured four types of body positions: right, back, left and front. Each position is represented as four coloured bars in the body position graph: red, blue, green and pink. In order to produce the artistic outcome of the experiment, each movement of the body was predetermined by a timescale that spanned the participants' entire sleep period throughout the performance study. This was outlined in the Contour Diagram.

SLEEP AS A FORCE TO BE RECKONED WITH

Much of this project has been about playing with invisible forces, whether they be the nature of sleep or our internal, intangible circadian rhythms. Recognising that sleep is a powerful force, I invariably experienced a sense of urgency when repositioning the bodies. This was because the body position sensor tracked and recorded every allocated posture it sensed every 30 seconds. Sometimes I was unable to move the body fast enough or, in a few instances, I had found repositioning difficult on account of resistance from the sleeper's body. Also, if the participant's body were to move of its own accord, which is a natural submission of the human body to sleep, I was responsible for gently restraining it and expeditiously repositioning it. This became a mediated guidance. On other occasions, the body position sensor

became loose on the belt. The result was a calculation configuring and recording of the ‘wrong’ body position, not the one planned and outlined in the sleeper’s Contour Diagram. Because of these features, my position and role within the room was crucial.

Technically speaking, if the body position sensor was placed in one position for more than 30 seconds, that position would be recorded on the sleep position graph. This then equated to a race against time, in that if the sensor was off kilter in some way, I had no more than 30 seconds to remedy the situation before it would be imprinted on the graph forever. And since one of the objectives of the studies was to create a replicated image of the participant’s chosen structure within the sleep graphs, every second – the equivalence of a line – counted. Working within this zone of urgency kept me alert and sustained my concentration throughout the night. Leaving a major factor of the project up to chance significantly aided my alertness and awareness, both of which were imperative in such a situation: struggling to stay awake, in a dark room, while watching someone sleep, throughout a night and into the early morning. What can be seen as the final product of each Somnolence Structuring is a graphic depicting coloured lines that match and those that do not. It is in these ‘happy mistakes,’ these moments of missing coordination, that the force of sleep is exemplified.

SLEEP ARCHITECTURE AS SOMNOLENCE STRUCTURING

The three architectural/landscape images chosen by the three different participants were the Parthenon, Monument Valley and the Perth city skyline. Each image had its own unique challenges and intricacies. Enacting the Parthenon involved an acute awareness of timing and a repetitive, simple motion. This consisted of only two moves, right and front, implemented precisely every half-hour for the entire night in order to give the shape and look of the iconic columns.

The vast expansiveness of Monument Valley, Utah, as enacted by the Somnolence Structuring, was translated into long stretches of time – periods of two hours occasionally – where no engagement with the sleeping body was required. And yet, in these lengthy durations were moments where alterations to positioning had to be conducted in precise 2–4 minute blocks of time. These motions were required for the final graph to reflect the intricate detail of the rocks silhouetted against the Utah sky.

The Perth city skyline is an image that most closely resembles that of ‘sleep architecture’ or a body position graph in its original form. Because most of the buildings on this horizon are flat rectangles, coordinating this structuring involved a relatively even balance of time spent positioning the body and time of non-engagement.

Along with observing sleep as an experience embodied within others, for me the Somnolence Structurings entailed comprehending sleep viscerally through a phenomenological approach. [8] Sleep, most often, just comes upon us, or over us; it sweeps through us. However, when it is taken away from us, it is, a form of a debilitation. Thus I come closest to understanding the essence of sleep when I deprive myself of it. The very lack – the very need – allows me to approach, as near as I now can, to grasping sleep, as that is when it visits us (while we are still in consciousness) in its most concrete and tangible incarnation. This could be said to be a universal experience, however, as long as we have not grasped its essence, its lack gives us a visceral experience and one way to attain a sense of it.

Rejecting notions of sleep as ‘an inactive state’ or ‘life’s little death,’ these body focused works became intimate engagements between artist and subject, who performed together while teetering between

transient states of consciousness – the artist being awake, tempted to sleep, and the participant asleep, waking slightly with every body reconfiguration. This duet emancipated the sleep laboratory bedroom from its purely scientific function.

Sleep, being outside conscious awareness, always escapes the observation of the sleeper. It can only ever be observed from without. There is a strong link between the impossibility of pinning down the lived experience of sleep and the unending variations and immense diversity in its representation within the arts. Like much art, Structuring Somnolence is playful as it is serious; it is a game played with nature in that I set up parameters and regulations as a sort of organisational tool or framework for the piece, knowing very well that in the end these will be ineffective as science and irrelevant to anything of a utilitarian nature. The act of carrying out an unconventional sleep study experiment as a performative artwork is, in and of itself, a reminder of the artificiality, the theatrical staging quality, of the sleep laboratory bedroom. With the data that emerged from the sleep technology commonly used to calculate and measure patient's sleep, together artist and participant forged a new configuration of graphics.

STRUCTURING SOMNOLENCE AT VISCERAL: THE LIVING ART EXPERIMENT

I was offered the opportunity to present my research at an exhibition entitled Visceral: The Living Art Experiment, which ran from January 25 to February 25 2011, held at Science Gallery at Trinity College in Dublin, Ireland. In essence, this rendering of Structuring Somnolence was similar to the experiments held in Perth: an all-night performance that produces certain outcomes – both intended and unintended – including a body position graph that mimics the outline of an architectural/landscape structure. As with the laboratory experiments, a volunteer sleeper and a sleep technician were required for this adapted version. On this occasion, variations to the experiment consisted of the environment in which it was situated and the technology used to conduct the study.

Structuring Somnolence at Visceral was an exercise that purposely invited unknowingness and happenstance. How would this live sleep event unfold amongst the myriad variables as a juxtaposition to the studies of the private, protectively encased sleep laboratory? Bedrooms specifically designed as sleep research facilities are crammed with technological apparatuses. However, with the advent of portable sleep measuring devices, also known as portable PSGs, it has become possible to gather data on a patient's sleep while that patient is removed from the laboratory setting by using Bluetooth wireless technology. The same technology was employed for this rendition of Structuring Somnolence.

This sleep study was to serve as a public performance event, a single nine-hour performance from January 28–29 2011, wherein people passing on the street became witnesses to the experiment taking place in real time, 9:00 pm to 6:00 am to be exact, only inches away from the glass façade of the Science Gallery. The portable PSG, was used to measure a basic electrode application set-up for a sleep study. In this gallery study, the participant sleeper chose to replicate the street block directly across from the Science Gallery. He liked the idea of mirroring what he saw and what he knew would be right beside him as he slept.

It was neither my main objective nor my main concern to wholly replicate the studies held at the Centre for Sleep Science inside Science Gallery. While the plan was to follow loosely the processes of conducting a sleep study with an artistic outcome, the concept behind Structuring Somnolence at Visceral, stemmed from a desire to see what would happen when we transported the sleep laboratory systematisation into an art space.

CONCLUSION: SOMETHING TO SLEEP ON

The investigation put forth by way of Structuring Somnolence was not to detract from the empirical values of science, but rather to highlight other ways of knowing and experiencing. Far from being a motionless and passive state, sleep has its own unique form of energy and dynamism. While scientific research has been among the ways of discovering this, one crucial role of art and my practice, is to defamiliarise all that we have named and categorised. This defamiliarisation serves as a reminder that sleep is a phenomenon, and that it is a lived, felt, forceful experience and one which can be expressed and interpreted in a multitude of ways.

The overriding demand to seek this 'truth' has led to evaluations carried out in artificial conditions (laboratories) with the subjects adorned in a plethora of clinical paraphernalia. As a way of approaching and addressing these matters anew, the development of this creative process focuses on harnessing the sleeping body as a means for drawing so as to repurpose sleep measuring and diagnostic devices for artistic gains.

BUILDING COMPLEX REALITIES: ARTISTIC USES OF LOCATIVE MEDIA AND AUGMENTED REALITY

M. Luisa Gomez Martinez

This text intends to analyze the artistic uses of LM and AR systems as indexes and catalyst of a paradigm shift in the relations between real and virtual spaces. This paradigm, articulated around notions as mobility or hybridization and concreted in “augmented spaces”, is understood both as a result and materialization of the epistemological paradigm of complexity that regulates the social construction of reality since postmodernity.

Throughout the 20th century the artistic realm underwent a progressive transformation due to its increasing intersections with technology. This caused a redefinition of the artistic object’s aesthetic basis and its relation with the spectator, but also meant the multiplication of genres and typologies linked to the new production, visualization and communication devices. However, in the last three decades and due to the Internet’s expansion, the aesthetic boundaries of art have rapidly extended beyond its limits thanks to a whole new set of technologies related to the Internet and based on different types of information processing which, every time more infiltrated within the socio-cultural environment, fluctuate between everyday uses and artistic applications.

Thus, after the development of Net.Art and the improvement of the Virtual Reality (VR) systems in the 90s, we have witnessed – since the beginning of this century – the development of new artistic forms related with the Locative Media (LM) devices and the Augmented Reality (AR) systems, which in turn are frequently combined and closely related to the development of wireless interconnection networks.

Without focusing on the debates that question the aesthetic specificities of LM and AR or, especially in the case of LM, its status as an artistic avant-garde, we are interested in analyzing their “artistic uses” as indexes and catalyst of a possible paradigm shift in the relations between reality and virtuality, a role that can be played thanks to the reflexive and experimental way in which the artistic practices use the new technologies as creative tools, therefore expanding – at a phenomenological and imaginary level – its potential uses and interpretations. This change in paradigm is articulated around mobility, reterritorialization and hybridization of spaces, and, at an epistemological level, signifies overcoming a dual and exclusive model of reality to give way to a model based on integration, multidimensionality and complexity.

Comprised in the term LM are all those communication technologies which involve localization; that is, that “provide a link or information related to a specific place by means of GPS devices, mobile phones, PDA, as well as portable computers or wireless networks.” [1] On the other hand, the term AR alludes to a data visualization system that involves “the laying of dynamic and context-specific information over the visual field of a user.” [2]

One of the novelties of these systems – in comparison with the technologies used in Net.Art or the VR – is that they enable new mobility logics. While the traditional interfaces for accessing Cyberspace – computers or VR helmets – implied a total or relative physical immobility in relation to the terminal, the LM in general, as well as the smartphones and other AR visualization devices, allow information to be instantly accessed from a fully mobile position. Therefore, to our infinite capacity of virtual mobility

through the immaterial networks and information fluxes – which allowed us to virtually overcome the spatial-temporal barriers in communication – we must now add the capacity for actual mobility. Apart from entailing a considerable increase in the complexity of our perceptive experience, it allows us to control information in our surroundings (now constantly re-defined and implemented with virtual information) and transform our relations with the same. This new relation to information corresponds to what Lemos defined as ‘informative territories’: areas in which the information flow on the intersection between Cyberspace and urban space is digitally controlled. [3] This produces what Manovich defined as ‘Augmented Space’: “the physical space that is overlapped by dynamic and changing information.” [4]

These new interactions with our surroundings through the ‘augmented’ flow of information on reality and the ability to control it, imply new ways of inhabiting, occupying and experiencing physical space; they make up different reterritorialization strategies that seem to challenge the widespread notion in the 1990s that the emergence of a Cyberspace and the potential virtual ubiquity involved a process of deterritorialization of subjects and objects, weakening their relationships with the material space and leaving it practically obsolete. Although some authors like Haesbert have deeply questioned the deterritorialization concept, [5] the truth is that some artistic practices such as Net.Art, VR and all those based on Tele-presence, have contributed to establish within the social imaginary the logic of a progressive exclusion of real space in favor of a virtual space which – as pointed out by Castells – absorbed all our social and cultural logics. [6]

However, the reflections and experiences proposed by the artistic practices based on LM and AR point at the reterritorialization and hybridization of spaces. Far from focusing solely on virtual space and pushing physical space into the background, they reevaluate the latter as a place of action with a geographical location: they make us reconsider our relation with space, redefining it through new potential/virtual narratives and rebuilding it by means of new socio-cultural routines based on physical mobility. In this way, the LM (proposing new pathways and cartographies based on social action over the physical space) and the AR (introducing a new paradigm in regard to Cyberspace where virtual objects are rendered on the physical space) promote a logic of spatial hybridization that reflects, manifests and materializes the complexity of our current technologically mediated reality.

The project *WalkSpace: Beirut-Venice* by Connor McGarrigle, currently on view at the 54th Biennial Exhibition of Venice, exemplifies the abovementioned within the context of LM. The piece consists of a tour through the cities of Lebanon and Venice, interconnected with each other in such a way that the tour through Lebanon is guided from Venice and vice versa. As the artist himself points out:

“The object is not to create a finite discrete work but to create a peripatetic relational space which can evolve and respond to the situation, the desires of its participants and serendipity, with the work being created through the actions of its participants. The space is furthermore overlaid with a hybrid, networked space connecting both cities and augmenting each space with the absent presence of the other.” [7]

The virtual ‘pavilions’ exhibited at the Biennale make up another example of this new relational paradigm between virtuality and reality, in other words, of the ways in which the physical environment is transformed aesthetically and phenomenologically through virtual information. The official project *Invisible Pavilione*, commissioned by Simona Lodi and the extra official projects of the artistic group Manifest.AR, transform the venue’s empty spaces into new AR pavilions, even setting a refugee camp on St. Marco’s Square.

The presence of these projects at the Venice Biennale, but also at many other exhibition contexts during the last years, can be understood as an attempt to demonstrate the new artistic possibilities offered by these media – especially by AR, which aesthetic and critical potential have only recently started to be explored by art. But is also symptomatic of the expansion of a new model regarding space and reality.

In this model, what is real and what is virtual are no longer experienced as two opposed territories in constant tension, but rather, become flexible and osmotic. Whereas, until not so long ago, it was only possible to penetrate the virtual realm, these types of practices have caused virtual information to leak into reality, altering not only our relationship with space and its aesthetic forms, but also creating a new concept of reality based on the synthesis of both elements, leading to an augmented, complex, hybrid and multidimensional reality in which what is real, virtual, imaginary and symbolic become inseparable.

The epistemological paradigm of complexity being developed since the beginning of the 20th century – subsequently spurred by cybernetic and information system theories – and which seemed to reach its full philosophical expansion during postmodernity, is no longer an accurate metaphor to describe a new reality, but rather, through the visual and visualized information accessed ‘here and now’, becomes an aesthetical and phenomenological experience that adopts the shape of an ‘Augmented Space’.

CHAMELEON: A STUDY OF EMPATHY

Tina Gonsalves

This paper will discuss *Chameleon*, an interdisciplinary video project exploring empathy and emotional contagion. *Chameleon*, shown at ISEA as part of the Australian Forum, is a six screen video installation, foregrounding emotional contagion and empathy. This paper will focus on the development of the cross cultural emotional expression video portrait database built for *Chameleon*.

Past work:

My work has always explored aspects of the intimacies and vulnerabilities of being human. In the past I have explored the emotional signatures of our bodies, using pulse, sweat, prosody and movement as agency for moving image interactive works that highlight the nuances of emotions and its importance in our lives. [1]

Universal Emotions and Cross Cultural Nuances.

When we feel emotions, they tell us something important about ourselves, our relationship with the world and our relationship with each other. The ability to read emotions in both others and ourselves is central to empathy and social understanding.

Researchers suggest that over eighty percent of human communication is encoded in emotion facial expression and body movements. In the 1960's Psychologist Paul Ekman traveled the world, from the USA to tribes in Papua New Guinea, showing pictures of facial emotion expressions to people. Following anthropologist Margaret Mead's theories, he had set out to establish the differences in emotion expression. To his surprise, he found more similarities in the way people express and understand emotions than differences. He concluded that the facial expressions of some emotions are not culturally determined, but universal across human cultures and thus biological in origin. He established that the five universal emotions that all cultures can read and respond to are fear, sadness, happiness, anger, and disgust. This research led Ekman to develop the Facial Action Coding System (FACS), a system for deciphering which of the 43 muscles in the face are working to express emotions at any given moment. Using FACS led to a verifiable database of facial expressions representing emotional states. This research revolutionized the study of emotions and although these images and research is now nearly forty years old, this verified database is still prominently used in most emotion neuroscience research today.

With in our own culture, the understanding of emotional expressions happens automatically and without much conscious awareness. We are highly attuned to subtle and covert emotional signals and people automatically and continuously synchronize with the facial expressions, voices, postures, movements of others. Through the dance of unconscious mimicry, we become carriers, infecting each other with our emotions, forging a bond with each other long before we utter a word, blending into the tone of our emotional environment. The face informs the self, not just others. One of Ekman's most fascinating findings is that if a person merely arranges his face into a certain expression, he will actually feel the corresponding emotion. This is the beginning of how we catch each other's emotions. Scientists call the mimicry of social situations the 'Chameleon Effect'.

However when we are taken out of our 'in-group', one discovers quickly that cultures do differ considerably in their use of emotional expression and cultural display rules vary about when, where, and how one should express emotions, how these emotions are experienced, the reactions they provoke and the way they are perceived. For example, research suggests it is Russians, closely followed by the Japanese and South Koreans, who most tightly control the display of their emotions, which may make Americans (who display the least control over their facial expressions) feel uncomfortable. In the West, we are more focused on the individual, with more attention to our own inner states and feelings, in the East one reads the emotions of a group with a lot more ease. As the complexity of our society broadens, when communicating, the overlay of cultural display rules can often get 'lost in translation', leading to a membrane of disconnects and negotiation.

Building Chameleon: An emotionally responsive video portrait project exploring empathy

With Chameleon, an aim was to investigate the social role played by the unspoken language of emotional expressions while exploring personal, technological and scientific biases and nuances.

To build *Chameleon*, we focused on three parts, the emotional code that triggered the video portraits was developed with neuroscientists Chris Frith, Hugo Critchley and Bruno Averbeck. The facial emotion reading technology that monitored the emotional expression of the audience was developed with affective computer scientist Rana El Kaliouby and Ros Picard at the MIT Media Lab. I directed the video database developed with everyday people sourced over the world. While developing *Chameleon's* code, the video database and interaction, we worked with Nadia Berthouze to analyze user experience. Working with curator Helen Sloan, we decided to take a more experimental and intuitive approach to exhibition, developing the work in nine progressions, turning each exhibiting experience into a 'lab'. We exhibited at a range of venues, including hospitals, museums and galleries.

Chameleon's emotional video portrait database:

Most scientists agree that we respond differently when we look at an image of a chair, and an image of a face. Intuitively I know when I see a face, I can feel my body shift, an awareness takes over my body. Science tells us that with the perception of faces, major activations occur in the brain particularly in the *fusiform gyri*. I was interested in creating a work that exploited our biological predisposition towards faces. [2]

I was interested in creating a new, more dynamic video database for emotion studies, and I hoped this could be of use for science. [3] It was important to shoot the work cross culturally to explore the cultural, social and individually determined responses to the six universal emotions being explored

in *Chameleon*. Faces are rich and varied, a brief glance of a face can provide us with knowledge to the individual's gender, their origin, their emotional state, their familiarity to us, their personality, their attractiveness or interest in us which in turn, influences our emotional response. I wanted to pick up on these nuances.

Over a year and a half, I set off over the world, asking volunteers to be filmed expressing emotions. Shoots often took place over weeks. The subjects were shot in a private studio space with a neutral black background, with simple lighting.

Technical considerations for the shoot

As a video artist, it was important to create *Chameleon's* video database using the medium of video. Although a 3D computer graphic rendered model of portraits would have been a much easier to create, easier to control, and more fluid, I was adamant that I wanted to document real people as part of the database. I was concerned about the 'uncanny valley' affect of 3D imagery. The theory holds that when renderings of people look and act almost like actual humans, they become overly "strange", thus will fail to evoke the empathic response I was looking for. At the beginning, I attempted to adhere to high production values using 3 HD cameras, large studios. I realized I needed to release this ideal and respond to the people I met everyday. I had my camera, a black sheet and made do with ad-hoc lighting so I could work with a range of people, in a range of spaces, in range of countries. I attempted a lot of continuity in post-production.

When creating the interactive design of *Chameleon*, it was integral to develop a novel interactive solution that matched both the conceptual and metaphoric content of emotional contagion. For a work about social emotions, it was an obvious choice to explore automatic facial emotion reading technology. It allowed for group interactivity, no training was needed with the audience and the monitoring of emotional state could happen from a distance, therefore a more fluid and seamless interaction loop could develop. Conceptually, interaction mode was delicate, provocative, and by analyzing the face, it was intimate. It also elicited awareness of these types of emotion recognitions technologies (both with fear and intrigue). We developed with the software with the MIT Media Lab (the software is called FaceSense). [4]

When designing the shoot, I was very aware that when the audience viewed the final video portraits, the emotional impact of the video portraits would need to trigger an unconscious emotional expression response in the viewer that the facial emotion expression technology needed to recognize.

Emotion Eliciting Techniques in the Studio

I elicited the emotional states using various techniques guided by my collaborators and others (psychologists, psycho-analysts, acting coaches, actors). For example, with disgust, I would ask the participants to view footage of people vomiting (that I had shot previously for a collaborative project about disgust). For surprise, I would talk calmly and then scream as loud as possible. For sadness and anger, I employed classical psychoanalytical techniques such as encouraging the volunteers to imagine different personal emotional scenarios from their past and to re-enact them as if in the present. I would often discuss personal emotional memories while shooting the participants facial emotion expression response to the stories. The studio time became a very intimate, vulnerable, trusting and often moving process for all involved. For a shoot to work, I learnt to listen attentively, subjects became friends.

Cross-cultural effects revealed themselves. One participant from Portugal displayed barely discernable emotions. North American participants were often the most vocally and facially expressive. Generally, participants from the UK had a harder time expressing anger. I wrote in my studio notes in March 2008 while working in Canada “...It’s taken a while to get comfortable asking people to evoke emotions. It’s been exhausting, because it feels so personal. It’s been a varied response, ranging from deep deep crying for half an hour to more laughter and very light expression..” Whereas my notes in April 2009, working in Paris “It’s harder to coax Parisians to reveal emotions... I need to spend more time getting to know participants, to develop a more trusting relationship. The studio time needs to be much longer than it was in Canada...”

On reflection, despite cultural differences, sadness was the easiest emotion to elicit. Most of the shoots resulted with the subjects in tears, sometimes deep crying lasting for up to an hour. I had to halt my intuitive response to step in front of the camera, to hug them, and make them feel better. I could only watch from behind the camera, and at most times, I ended up crying as well. After the shoot I asked the participants to reflect on the experience. “I felt messy and really really sorry for myself and very very lonely which made me feel even sorer for myself... I felt like she (the artist) had been my therapist and that I owed her £50 for the session”. (email correspondence with artist August 2009)

I had developed a database of emotional expressions that were both felt and also acted. At first, I was on a ‘search’ for authentic, felt emotions, however, I soon realized that this was not important. In everyday we express emotions that are not ‘felt’, and their primary purpose may be some sort of manipulation. In everyday life, we seem to have an embodied awareness which drives a constant search of each others’ faces for truth. I also wanted this dynamic to evolve in *Chameleon*.

By the end of the project, I shot 30 participants, adding up to a 23-hour database of mostly non-verbal facial emotional expressions.

Post production

This material was treated carefully. Some footage was edited, as the footage would have been detrimental to the participants, as it was too private. Some footage was given back to the participants, to make their own works from. I edited the work by assigning in and outpoints for each emotion. I wrote in my blog in August, in Brighton 2009: “...I have built up compassion and attentiveness in the studio, I then have sat and analyzed and categorized that footage – more as looking at narrative and science of what an emotion is. This process has felt harsh – as if I am fragmenting a lovely relationship, objectifying it, making it into a production”.

Audience Response to Chameleon

The work was exhibited often, with most exhibition venues providing a chance to evaluate audience interaction. We tested a range of scenarios, with different types of screens (3D, low pixilation, High Definition, sculptural), displaying different portraits. We worked with the UCL Human Computers Interaction Center to evaluate the work.

Throughout the interviews of participants, feelings of intimacy came up repeatedly in the interviews although they were not explicitly part of the questions. In many cases the audience was affected by the emotions expressed by the characters, and the constant search for meaning and introduction of context

generally followed this. *"I was thinking of some sad things that happened to me, when [...the digital portrait] was sad for a while, it felt like a long time, and it reminded me of some things."* Also, *"I didn't like it when he looked sad and I didn't know why."*

A goal of the work was to bring up reflective questions about our own emotional expressions. *"I made a man start to scream, which was a little worrying - did I look like I needed to scream? Did I look frustrated? I then of course looked worried, which made someone else smile to make me feel better..."* Another reports that the lack of interaction had made one question their own facial expression *"maybe I have got a tired face, umm... and sometimes when I am not smiling people say to me 'oh cheer up, as if your ... you know, maybe I do give that off instead of my feeling like I am emotionally upset or angry."*

Exciting initial feedback suggests that the contagion of emotion leaks out of the gallery spaces. *"I went out afterwards and felt like I was picking up the feelings of everyone I passed."* My hope was that *Chameleon* reminds us that our body as a clear-cut distinction with the rest of the world is dissolved, revealing that we are all interconnected.

The Art and Science collaboration

Chameleon successfully brought together a genuine and rare collaboration across the boundaries of arts and science, creating art installations, research papers, and novel, more dynamic models for scientific research. I was very aware, in choosing the title *Chameleon*. It related to the project, but it also reflected my artistic role. As I collaborated, looking at my work through new lenses, I was moderating my language accordingly, depending on whom I was working with. My work was becoming a synthesis, influenced by the qualities of multiple collaborators, attempting to reach a balance that would meet the needs of each collaborator. I felt like a Chameleon, shifting, adapting, a 'changing self.'

The scientists involved in *Chameleon* reported feeling a sense of 'freedom': Chris Frith sees the cross disciplinary collaboration as liberating: *"This project has developed far beyond what I would dare to do in the carefully controlled experiments that we are restricted to. But the end result will provide us with marvelous tools for doing new experiments."* Nadia Berthouze writes: *"I see Chameleon as a source of ideas for the creation of digital environments conducive to patients becoming aware of their emotional states"*. Rosalind Picard, who is mentoring the building of the face reading technology, is interested in its use for people with autism: *"As I watch people to learn from the interactions portrayed. These are scripts with naked emotion, uncovered, and whether ugly or beautiful, they are hard to turn the eyes from. Here is an engaging palate for helping people who don't naturally understand emotional interactions, and who want to deepen their ability to do so"*.

I would like to acknowledge the in kind support from the MIT Media Lab, Banff New Media Institute, SCAN, Fabrica and Institute of Neurology at UCL. The project is funded by the Wellcome Trust, Australian Network for Art and Technology Synapse Residency, Arts Council England, Lighthouse and the Australia Arts Council.

2. *I had had an interest in dynamics of portraiture for years. In earlier work such as Feel: Trace (2005), and Feel: Ferment (2006), I had began to explore the static facial emotion recognition databases most often used in emotion research such as the Ekman and Friesen Database, and the Karolinska database. In Feel: Insula (2007), I had begun the creation of a new moving image portraiture database that searched for a more authentic expression of emotion. Over a few months, I worked with clinical hypnotist, David Oakley, asking him to hypnotize me into different emotional states to create a more genuine representation of emotional expression. This became part of a video installation, and also the voice track for a short film, Feel: Melancholia (2007).*
3. *A large percentage of current scientific experiments exploring facial emotion expression uses Paul Ekman's 1970's visual database of static facial expressions representing emotional states. Since I finished the database in 2010, I have had quite a few requests for the database to be implemented in science studies.*

ELICITING COMPASSION : AN ARTIST IN RESIDENCY AT THE MAX PLANCK INSTITUTE, LEIPZIG

Tina Gonsalves

This talk will discuss my residency (funded by the Australia Council's Inter Arts Board) based at the Max Planck Institute for Cognitive & Brain Science in Leipzig, a research center in Germany working with the director of the social neuroscience lab, Prof. Tania Singer. Singer's research area explores the role of trust, compassion and altruism in our lives.

PROBING THE PSYCHO-PHYSICALITY OF EMOTION

As an artist, my work has always explored the emotional body through drawing, painting, collage, video and interactivity. I met Prof. Tania Singer, director of the Social Neuroscience lab at the Max Planck Institute for Cognitive and Brain Science in Leipzig, six years ago, when I was immersed in a year-long fellowship Arts Humanities Research Council/Arts Council England fellowship at the Institute of Cognitive Neuroscience (ICN) at University College London (UCL). I was at the ICN working with neuroscientist, Hugo Critchley whose research explores emotional psychophysiology, and Singer was part of Critchley's group.^[ii] Singer was at the ICN working on some very interesting experiments exploring the effect that love has on empathy. At this time, Singer had just began developing her interest in how meditation may impact the biology of the brain. Singer invited me to the initial meetings at the ICN with Matthieu Ricard, a Buddhist monk, French interpreter for the Dalai Lama and member of the Mind & Life Institute, an organization dedicated to collaborative research between scientists, Buddhist scholars and meditators on the effect of mind training and meditation on the brain. Singer began scanning Ricard's brain while he meditated in the fMRI scanner. I found it fascinating.

EXPLORING SOCIAL EMOTIONS

After my fellowship with Critchley, I began to work with social neuroscientist Chris Frith. Singer was part of both Critchley's and Frith's research groups. I initiated a residency at the Wellcome Department of Neuroimaging at UCL, working Frith. I was curious about how our sense of self arises from our need to map relations between self and others. Frith was discussing how a building block of human interaction is emotional contagion, the tendency to catch and feel emotions of others, so that we automatically mimic and synchronize with the vocalizations, postures, and movements, converging emotionally. Emotional

contagion can sow the seeds of empathy, as one then begins to identify with another's feelings. We embarked on a video project called *Chameleon*, exploring emotional contagion and empathy. Over nine prototypes, we worked with a range of research institutes to transform scientific, technical and visual theories of emotional transfer into poetic interactive installations driven by emotions of the audience and the portraits on the screen. Each day the mood of the *Chameleon* portraits adapt to the range of visitors' emotional expressions, affecting the tone and emotional ecology of the gallery space. I worked with a team of human computer interaction scientists to study audience experience. *Chameleon* was successful in exploring the concept of empathy and foregrounding emotions.

ELICITING COMPASSION

Chameleon led me to contemplate ideas of compassion, and how it could be highlighted in the interaction scenarios of the work. Compassion is a complex state of being. Empathy explores the feelings of another. Compassion requires empathy, and it also requires a time investment, as one feels compelled to alleviate or reduce the suffering of another. The Dalai Lama discusses compassion in dialogue with Paul Ekman in their book 'Emotional Awareness: Overcoming the Obstacles to Psychological Balance and Compassion'. *"... It is translated as a sense of connectedness, a sense of endearment to others, where the idea is cultivating a state of mind that makes the sight of others' suffering unbearable to you. Cultivation of that is the crucial component of compassion. It is said that the stronger this sense of connectedness, the greater your feeling of unbearableness when you see others suffer. . . . When you reach that state of mind, then others are seen almost as an extension of yourself, as part of you."*

These thoughts led me to contact Singer. Since our first meeting six years ago at the ICN, Singer, along with other renowned scientists, had been working with the Dalai Lama and his close circle exploring the biological effects of compassion meditation on the brain and body. I was intrigued by Science's interest in incorporating a more holistic approach to knowledge. I was also intrigued by Buddhism's interest in science *'offering powerful tools for understanding of compassion, revealing the interconnectedness of all life, and that such understanding provides an essential rationale for ethical behavior and the protection of the environment'*. (Dalai Lama)

In 2010 Singer was awarded a large European Research Council (ERC) grant to research "Plasticity of the Empathic Brain: Structural and Functional MRI Studies on the Effect of Empathy Training on the Human Brain and Prosocial Behavior". We decided that the time was right to begin a residency.

In September 2010, I began the journey to the Max Planck Institute in Leipzig, Germany, meeting with Singer, and her ever-growing team. Singers' approach is multi-method and interdisciplinary, combining techniques and paradigms from the fields of neuroscience, bio-psychology, economics and the arts. The ERC grant will encapsulate an ambitious longitudinal study, taking place over a twelve-month period (the initial starting date was March 2011). Up to 200 subjects will be recruited. The subjects will have little or no background in meditation techniques. Over a year, they will undertake compassion training, while partaking in everyday life. They will be monitored up to six key times over the year (fMRI scanning, pathology, self reporting). This is a leap beyond previous studies as most studies of compassion training usually take place over a shorter period. The training usually takes place in a 'retreat' type of environment and the subjects usually have some meditation background.

Over the study period, the group are investigating the degree to which short and long term affective and cognitive training can significantly induce functional and long-lasting structural neuronal changes in the brain and lead to pro-social behaviour. They are also looking to the hormonal, health-related, and behavioural changes.

As an experiment like this has never been done before, much time has been spent discussing approach. Over long meetings, protocol and ethics considerations get refined. We discuss the importance of appointing the appropriate teachers to administer the compassion training. My role has been to brainstorm how we can use technology to create 'compassion interventions' with in everyday environments. Each of the subjects will be given a mobile phone that will be both a reporting tool and a tool to elicit compassion. A secure web based 'meeting point' may stream meditations, hold each days learning activity and become a place to share stories of compassion. It may also hold questionnaires, options to upload comments and chat online with subjects.

In July 2011, Singer held the "How To Cultivate Compassion Workshop" to refine the protocols, teachings and ethics that will be implemented in the longitudinal study. The workshop was based at the Studio Olafur Eliasson in Berlin. Eliasson is an Icelandic contemporary artist known for sculptures and large-scale installation art, employing elemental materials such as light, water, and air temperature to enhance viewer experience. In 1995 he established the Studio Olafur Eliasson a laboratory for spatial research where he collaborates with scientists, artists, architects and engineers. Eliasson is working with Singer on a compassion based project from the 2012 Olympics. Over four days, a mix of neuroscientists, psychologists, psychotherapists, academics, Buddhist monks, artists and like-minded international researchers studying compassion gathered. The approach to this gathering was more experiential, less didactic. Powerpoint presentations, 'p' values, graphs and statistics were not high on the agenda. Instead the discussions about compassion moved into 'interventions', so each of the researchers can 'experience' the teachings. This was matched with macrobiotic vegan food and group meditations designed to elicit compassion. Throughout the 5 day meeting, I found myself crying often! Reflecting, many of the Scientists were walking around Eliasson's studio with red and swollen eyes, which resulted in a lot more discussion, hugs and also laughter. For all involved, it was a felt, compassionate learning experience. I find this multi-method approach of Singer's is intriguing and inspiring. Out of the workshop she gathered committed key advisors to help oversee the study.

To me, it seems Singer is also attempting to 'live' the study. When we discuss the study, she often speaks about it very personally and her words become emotional. She talks of meditating daily and often attending meditation retreats. Quite a few members of the group meditate each day. Before I arrived, Singer and her research group undertook an eight week Mindfulness-Based Stress Reduction (MBSR) program together. The course was developed Jon Kabat-Zinn, at the University of Massachusetts Medical Centre. He sees it as '*a way of learning to pay wise attention to whatever is happening in your life that allows you a greater sense of connection to your life inwardly and outwardly*'. The MBSR program started in 1979 and is now offered in over 200 medical centers, hospitals, and clinics around the world. The training teaches methods of stress-reduction and formal practices in mindfulness meditation, encouraging the development of greater compassion. The group reported that undertaking a course like this with work colleagues was enlightening, vulnerable and strange. However, it did lead to a lot of the key issues that the subjects will encounter when undertaking the longitudinal study: Attendance motivation, ethics, the importance of great and inspiring teachers, the importance of keeping the study secular, and deeper issues of trust and sharing.

CREATING COMPASSION INTERVENTIONS

My role here is viewed in many ways. Some researchers see art as a way of making the science more accessible, working well for public engagement. Others see it as the illustrations of concepts, communicating new ways of seeing, moving the science forward. I see my main role here is to influence the 'design' of the protocols. Artists often investigate ideas in different ways than scientists, allowing fresh perspectives. My knowledge in biosensors and creating 'emotive' video content, as well as my work with mobile technology and the web has influenced the structure and delivery of the protocols. I have been working on a range of video databases that may elicit feelings of calmness and altruism and anxiousness. Throughout the residency I have been holding 'compassion' interventions with in the lab and the other departments of the Max Planck Institute. One intervention created 'moments' of compassion, asking the researchers to define compassion, discuss personal memories where compassion was the primary feeling. Another explores how compassion renders itself on the face, asking the researchers to look at the video camera while mediating on compassion.. Another intervention explores a heightened awareness of time, inspired by Marina Abramovich 'The Artist is Present', and psychological studies, I asked participants to sit opposite me, as we sit and non verbally communicate for two minutes.

While at the Max Planck Institute the aim is to shift this research into *The Nowness Project*. This series aims to disrupt 'communication' technologies that have become embedded into our everyday social interaction, revolutionizing the way we share information and experiences to those close to us. In particular, I have been repurposing live chat, video conferencing such as skype, and social networking tools. I was interested in the idea "*We are more connected than ever, yet people report feeling lonelier and more isolated than ever*" (Cacioppo). By understanding more about compassion, I am hoping to embed compassion eliciting techniques into the coding /visualization/performance design/ interaction strategies of the work creating 'compassion interventions'. We are negotiating if and how we can implement these into the studies.

The first prototype we have been working on is *Present Perfect Continuous*. Audiences will download a chat programs/widgets to their own computer systems/phones. The objective is disruption: Audiences will have to rethink habitual communication response as the chat program will only allow them to talk in present tense.

The second prototype in production is called *Unravel*. It explores, via chat program interventions how language shapes our emotional feelings and how we make sense of the world around us. Objective is intimacy: The work will look to neuroscientific paradigms to probe the emotional content in text (rapid linguistic processing) aiming to recognize when emotions are expressed in text and then generate text with specified, more overt, expression of emotion eliciting questions.

The third prototype is called *Percolate*. It uses eye display technology developed by Nokia Research Center in Finland. As a phone call begins, a captured image of the conversants' eyes is transmitted to each conversant via the eye display technology. The conversants look probingly into each others eyes as they converse. The objective is to create new, more intimate communications by breaking down the usual social ritual of body space and cultural difference in gaze frequency and duration. At the Nokia Research Center, we conducted an explorative user study in a laboratory context with five pairs of users to understand their experiences with this system. The results show that this kind of mediated communication can cause a variety of experiences, such as "interesting", "surprising", "tranquil" or

“pleasantly strange”. Overall the user study suggested the full-screen display appears to create a more focused communication, and thus can help make the discussion more intimate and focused on the moment. We envision that a system like this could become a tool for deeper listening.

A fourth prototype is called *Take a Look Through My Eyes*. Research suggests that imagining yourself in ‘someone else’s shoes’ helps increase your empathy for their plight. This prototype reworks skype and eye display technology to transpose each other’s vision. First person viewpoint of video is taken through video attached on eye display. This is streamed to each of the conversants. The video facing the conversant’s eye is also captured. This is masked, for example, we can experience when each other blinked, stared, changed eye gaze. *Take a Look Through My Eyes* allows us to escape the confines of our own worldview, and allows them to see things from each other’s perspective – the beginning of empathy.

A fifth prototype *Ponder*, is an intervention that allows one to ponder on oneself. Most communication devices allow us to communicate with others. This communication device allows one to communicate with oneself – an intrapersonal communication. Glasses are repurposed with mirrors, so the wearer can only contemplate at him or herself.

A sixth prototype *Breath* is an application that sends out a sonic breath file to computers and phones at key times, as a small intervention to remind people of the present.

The Max Planck residency has provided a platform and a reflective space to conceptualize and produce projects, share ideas and knowledge while learning more about the themes that are essential to my work. The institute and Singer have been generous in supplying a private office, access to the building, researchers, all talks, and organizing access to an apartment in Leipzig. Although the actual study has been put back to 2012 (due to the logistics of housing new scanners, construction of new buildings, refining protocols), both Singer and myself are now investigating how I can spend more time in Leipzig to be involved with the actual study in 2012.

References and Notes:

Critchley's research in interoceptive awareness (consciousness of internal bodily state) was integral to my work. At the time, I needed to know more about the body's signatures of emotions: how to probe, entrain and monitor emotions to create emotionally responsive video installations, generating an awareness of the internal sensitivities of the body that we usually ignore. Together, we created Feel_Series (2005/06/07), a series of installations that responded to heart rate, sweat and movement. We also created a range of visual databases for use with in Critchley's scientific experiments to probe different emotional states.

THE USE OF ANIMATION IN THE GENERATION AND DOCUMENTATION OF IDEAS IN SYSTEMS PAINTING

PAUL GOODFELLOW

This is a review of my personal application of animation techniques to analyze and document visual rules within in systems based approaches to painting. I describe my art process and how animation is used to document visual decision-making at each stage of the work's development. This process allows me to capture any deviation from the system. My interest is to document the intuitive decision making processes within a controlled environment

Figure 1, Berlin Walk, (Color Study detail), 2011, Paul Goodfellow, Digital Film

Figure 2, Berlin Walk, (Composition Study detail), 2011, Paul Goodfellow, Giclee print, 422mmx297mm

Figure 3, Berlin Walk, (Detail), 2011, Paul Goodfellow, Acrylic on canvas, 1600x1220mm

This paper will summarize the systems art making process of the author and how animation is used to generate ideas and document visual decision-making processes at all stages of the development of a piece of work. This paper is written in the first person, where it relates specifically to the authors personal experience and work.

As an artist with a systems background, I am interested in the borderland between systems based approaches to investigation and intuitive experimentation in art. In thematic terms I am interested in applying this to the areas of environment and place and how this can be experienced and interpreted as an artist in four-dimensional space and how this can be reduced to an essential representation in a painting.

SYSTEMS ART

Systems have been identified within most disciplines and in simple terms can be described as a set of integrated elements that form a coherent whole. Boulding noted that ‘a system is anything that is not in chaos. We could turn the pattern around and define a system as any structure that exhibits order and pattern.’ [1] Systems theory, as applied to art grew from a group of conceptual artists in the late 1960’s, such as Burham, Haacke and Sol-Lewitt who referenced Weiner’s Cybernetics, and Von Bertalanffy’s General System Theory in their writing and work. Their work was concept driven and organised by rules, and although referenced or incorporated technology made a distinction between their conceptual art and art-and-technology, (electronic art). Sol Lewitt’s noted the divergence between conceptually driven cybernetic work and technology driven work in his essay “Paragraphs of Conceptual Art” (1967). He described conceptual art as a quasi-mechanical process: “In conceptual art the idea of concept is the most important aspect of the work . . . [t]he idea becomes a machine that makes the art.” Whereas electronic art was in danger of being uncritically focused on the materials and the spectacle of technology. As Sol Lewitt’s stated “new materials are one of the great afflictions of contemporary art. . . . The danger is, I think, in making the physicality of the materials so important that it becomes the idea of the work (another kind of expressionism).” [2]

A key figure in Systems Art is the artist Hans Haacke. In 1971 he proposed a Guggenheim show in which a caged Mynah bird repeated the words ‘All systems go’. Haacke could not train the bird to repeat the phrase though, and the project was treated as a conceptual proposal. The suggestion in the title is that ultimately all systems are open, and subject to failure or uncontrollable external factors. In an earlier work, (Chickens Hatching, 1970), Haacke had created a controllable system that relied on a simple feedback system of lamps and thermostat to control the hatching of chicks. This contrasts with ‘All systems go’, as the later work relied upon a parameter that could not easily be moderated in a system; namely the bird talking. [3]

I am interested in the space between these two works. I am interested in controllable systems, and the limits of controllable systems. I am interested in the role of the artist, and whether the Mynah bird’s free will represents the free will of the artist to submit completely to a system, or even the viewer and their role in the wider distributed system.

BACKGROUND

I originally worked in development of Geographical Information Systems, (GIS), for environmental and development projects. I was drawn to the way complex physical and social systems were integrated, modeled and visualized spatially and temporally. In my research I was coming across spatial and temporal patterns and phenomena in the data that could not be explained by the defined system or model. I was finding visual patterns in the data through intuitive visual manipulation, (such as animating the data over time), that could not be readily explained by subject specialists. I did not understand how I could perceive patterns in the data, when the system could not support such a finding. Thus the system required constant revision to accommodate the new findings. Alternatively the limited models could be understood as offering a supportive framework to interrogate the data to a certain depth, but ultimately the last step required an intuitive leap of the imagination. It was this borderline between a well-defined system and the transgression of the system that fascinated me, and continues to fascinate me as an artist. How systems are revealed, revised, transgressed and fail.

WALKING AS AN ART SYSTEM

Collecting experience and information through walking is a personal attempt to bring the technological approach of spatial analysis in the forms of GIS and GPS along side the surrealist, aesthetic and impressionistic approach of visual art. This duality of objective and subjective is accommodated in the ideas of Psychogeography. The origins of Psychogeography can be traced back, primarily to Paris and to Charles Baudelaire's 1863 essay, *The Painter of Modern Life* in which he described the Flâneur, "a person who walks the city in order to experience it." [4] The first major written work by a Flâneur practitioner was the unfinished *The Arcades Projects* by Walter Benjamin in which he documents in great detail his walks and interactions in the former arcades of Paris. This idea of the passive urban stroller was transformed in the 1920's by the founder of surrealism André Breton who used the urban stroll as a positive tool to challenge perceptions of reality. Over time the perceived failure of Surrealism to reform society through these methods new, more explicitly political groups developed that played on surrealist ideas. The Situationist International, under the direction of Guy Debord did much to define Psychogeography as it is understood today. At the heart of Psychogeography was the aim of combining subjective and objective knowledge and studies and Debord attempted to resolve this inherent paradox in his 1958 book "Theory of the Dérive." [5]

On another level my work references environmental art and artists, such as Richard Long and Hamish Fulton. Long, for example, has based his routes on geometry, giving his walks structure and a self-contained composition. Thus he avoids any sense of ritual or potential narratives, such as the following of Ley Lines. He has also removed any historical associations from his paths, to concentrate on the geometry. He uses systems to keep his choices to the minimum, so the walks don't become a personal response to or expression of the landscape. In contrast my walks, although based on systems, (which can include geo-information, maps or socio-economic systems,) are a way of finding the point where I can transcend the system in both walking and mapping terms and express a deeper essence of the place, as articulated in Heidegger's conceptions of place and topology. [6]

On a practical level walking has been chosen as it is a direct way of experiencing a place qualitatively, and a useful way of capturing data quantitatively, due the relatively slow movement through space. A walk can be defined as an art system that produces outputs, which in turn is representative of both the environment and sense of place. The walks I make are a private performance that is recorded. The art work made from the walks are a culmination of organizing and interrogating the recorded information in

a systematic way, and then transcending this order to make controlled, but spontaneous decisions during the final making process.

METHODOLOGY

I take a walk and document the walk with digital cameras, and log the positional information with a GPS device. I use this as source material to make animations that map the walk through the duration of the film. I also attempt to reduce the walk to a single image by collapsing all the frames into one image. This is made into computer-generated images, drawings and paintings.

The work is based on a set of procedures for the collection, organization, and manipulation of the source material. The source films are re-played and manipulated in real-time through a set of systematic rules that are controlled through numerical ranges, and digital controllers, as you would a computer game. At this stage the work being created is a mix of programmed rules and variables that are being manipulated by the controller. It is therefore a piece of work that is contained within a rigid set of rules, albeit one that allows for a range of choices. Animation is crucial at each stage of the creative process and these will now be described in order.

Stage 1. Data collection using stop-motion animation

During a walk a time-lapse camera is worn on the chest. This automatically takes a photograph every 10 seconds, and a GPS logs the position. The geo-located images from the walk are turned into a stop-motion film.

Stage 2. Studies in color using real-time & procedural animation

Using a digital drawing tablet a continuous line is drawn over the film, directing the pen to sample colours and aspects of the photographs that interested me. The line produced is combination of sampled colours and sampled photographic details. In my other hand I controlled a set of midi sliders to control parameters such as sample size. This process requires a continuous line to be drawn for the duration of the film. See Figure 1.

Stage 3. Studies in composition using real-time & procedural animation

During this stage compositions can be generated in real-time through a combination of intuitive interaction with certain parameters using midi controllers, and procedurally controlled parameters that are driven by data, such as altitude. From this process several outputs can be derived. These include computer-generated prints, drawings based on paths taken from the GPS, (gpx), files and detailed studies for compositions. See Figure 2.

Stage 4. Painting development using projected animation

The real-time animations made at the composition stage are complete when I am happy with the composition. As this is recorded as a film I can scrub backwards and forwards through time to understand how the image has been constructed and use it as a guide for the construction of a painting. At this stage the animation is projected onto the canvas, and used as a frame of reference. The overall composition of the painting will be taken from the animation. Each new element appearing in the animation

denotes a new element for the painting. For each of these elements I need to make an explicit decision on the canvas; whether to use the 'design' from the animation or to make changes in terms of color, shape and position. The only factor that will not change is its relative layer of painting, as this equates to its position on the timeline. See Figure 3.

Stage 5. Capturing the painting process using stop-motion

During the painting process the canvas is photographed with a camera using remote control shutter control. This captures the addition, subtraction and alteration of each new element. Thereby capturing each painting decision that deviates from the animated version.

Painting is a modest way of fixing variables and glitches in material, that stands in opposition to the increasingly interconnected and ephemeral distributed system of commodified communication and consumption. Painting captures the spatial and the temporal, and all the decisions that have been made regarding the construction of the painting. It condenses time-based work or systems into a single frame. It allows the artist to take something temporal, held mentally and make it visible, non-linear and compositional. It is an antidote to technology, programming, and perfect closed systems, as it is a way of having closure, forcing commitment to the material world. Painting is time-dependent, the drying paint forces decisions within a certain time frame.

Stage 6. Post painting time-based analysis using compositing techniques

The final stage is to replay the real-time animation created at stage 3 and the stop-motion animation created at stage 5 simultaneously. Firstly these will be played adjacent to each other, and secondly they will be overlaid using compositing software. This will highlight the differences between the two works, and these differences can be extracted as a new film. In essence this Boolean operation will generate the difference between the two works, and make explicit where I made decisions that deviated from the system. I am interested in the boundaries between these systematic rules and the intuitive real-time decisions in these works. I am interested in mapping out the systematic, and highlighting the intuitive. A key question to explore in the future is whether there is a difference between decisions made in real-time on the computer in a structured environment, as compared to real-time decisions made in painting in a structured environment?

CONCLUSIONS

There is no such thing as a perfect closed system or model in the real world that perfectly reflects the phenomena it seeks to represent, as there will always be variables that you cannot account for. A system therefore can only be an approximate model of the real world. Likewise a systems-based approach to painting can only be an approximate model, and cannot explicitly encompass all the decisions a painter makes during the painting process.

Animation is used to document the systems methodology I employ at each stage of the creative process. It allows me to capture any deviation from the system; to map the randomness, and chaos. My primary interest is to document in a time-based way the intuitive decision making processes taking place within a controlled environment. Animation is an excellent method for such documentation. Ultimately I am interested to understand what this might say about the relationship between intuition, conscious and sub-consciousness decision-making in art.

THE MATERIALITY OF DIGITAL UTOPIAS

Baruch Gottlieb

The citizen creator of the current age is advertised to be empowered of unprecedented means for transforming the world. This paper will attempt to evaluate the Utopianism of the digital age with reflection on the material circumstances of the hardware expected to realize it.

Can we see in the predilections of our hardware the concretion of the certain social priorities? Can such social priorities be said to invoke ethical models? And if both questions can be taken, can we then infer that ethical values are inscribed in our hardware? If the response to the last question is positive, as I would like to argue, we have a situation where the highly miniaturized, multiplied automated processes of the hardware that makes today's industrial reality run are perpetuating certain moral values, and that these moral values deserve discussion.

The materiality of our contemporary environment is the product of large, to varying degrees global processes involving the collaboration of myriad people, excavating, working, thinking, planning, moving the materials around until they have settled in the forms we can observe here today. The production of the contemporary surface requires collusion, as Bruno Latour put it "An object cannot come into existence if the ranges of interests around the project do not intersect." [1] these overlapping ranges of interests constitute society. Therefore there is a sociology, and an anthropology to the present and it is grounded in the past, and, going further I claim, the physical reality of contemporary objects are, materially inscribed with the social processes by which they were generated.

If our technology is ingrained with, and propagating, social and moral messages, it is important for artists and critics to inscribe themselves there. When Flusser said "true freedom is to turn the accident around and make something, which was very improbable necessary," [2] he was speaking of Dante writing his *Inferno*, how unlikely it was that he wrote it, and how it became historically necessary in retrospect. This is exactly the kind of retrospective necessity we need to generate today. We should not take what has happened (the accident) as necessary, but decide what unlikely thing we wish to have become necessary in future retrospect.

I would maintain that there is, at every moment, the possibility, even the propensity for technology to be different than it has been in the past. Technology, as a human product is the site of a battle for ideological hegemony, thus claims of its neutrality are politically spurious. We could, from today, have a very different world of technical effects and objects, engendering different world-views and sociabilities, if, or course, the "ranges of interests" of enough people involved would intersect to support enough divergent projects.

It would appear that our age is very well disposed to exploring alternative social modes. Instead we have a society which is profoundly conservative, prey to the least threat of insecurity, constantly assailed with threats of various kinds, air and water pollution, distant and immanent wars and terrorism, global environmental disaster, etc. The litany of dangers reformulated endlessly over the course of every day's news feed, engenders an atmosphere of insecurity which cows populations into submission to any

regime which promises to protect them. In other words, despite superficial technological advance, politically we are still living in the 1700s, if not the 1300s. This fact alone casts significant aspersions on the claim of the neutrality of technology.

Let us take, for example, design errors which caused the deaths of (according to the US Congress) [3] over six million people. A holocaust broke out in the late nineties when engineers at Apple, Nokia, and other electronics manufacturers determined to use tantalum in their circuit boards. Tantalum's unique heat-resistant and high-conducting properties allowed the next generation smartphones, games and laptops to be designed thinner and lighter. Nobody asked where these materials would come from. Wars broke out for control of mines in DRC and Zambia, and millions were killed. This was patently a design decision which went wrong. Is the design neutral? Obviously not.

In 2002 the European community decided to ban the use of lead in solder. The project was called ROHS, it came into full effect in 2006. Other, safer alternatives to poisonous lead, such as tin, were available, which would protect tens of thousands of electronics assemblers around the world. No-one asked about where the tin would come from.

World-wide transition to non-lead solder for electronics meant that massive and inexpensive new sources of tin would suddenly have to be found. [4] Suddenly a civil war sprung up in eastern Congo over cassiterite (tin ore) mines, [5] hundreds of thousands were raped and murdered as militias, and sections of national armies, often supported by multinational mining corporations battled for control of the mines. There will be no Nürnberg for the inadvertent bureaucratic criminals, who simply though ignorance generated mass slaughter.

Since the earliest days of our 200-year industrial revolution, and before, back through to our philosophical ancestors in the Greeks and Egyptians, we have a certain tolerance for collateral damage, human exploitation, slavery, indentured labour, in the interest of social progress. We need to see that cruelty as part of the pedigree of our indubitable technological and scientific accomplishments. My point is that we cannot plan, or even envisage a technical utopia that is conveyed on hardware created under intolerable conditions. I deny the neutrality of hardware as I assert its persistence as a record, an archive of the social conditions of its emergence. As Garcia & Sandler concluded in their article about whether human technological enhancement could help resolve social justice problems "We must fix social injustice, the technologies will not do it for us." [6]

The engineers and designers, after all, were just looking for a practical solution for a technical problem, how to get as much heat resistance and electrical efficiency in the smallest space possible. Their negligence can not be abstracted from their competence, we need to take a sociological/anthropologic view of these specialists and attend to what is motivating them to make the decision they did. Following from Latour, Johansen, [7] Traweek, [8] my own field research, and that of others, I claim that the decisions of the engineers were based on their immediate social needs inside their company, ethical concerns about any possible repercussions of their actions were not significantly considered. Their quest for status by having solved the design problem overruled their ethical skepticism. They hide whatever shame they have behind a simplistic notion of progress.

"The various manifestations of socialism destroyed both their peoples and their ecosystems, whereas the powers of the North and West have been able to save their peoples and some of their countrysides by destroying the rest of the world and reducing its peoples to abject poverty. Hence a double tragedy: the former socialist societies think they can solve both their problems by imitating the West; the West

thinks it has escaped both problems and believes it has lessons for others even as it leaves the Earth and its people to die. The West thinks it is the sole possessor of the clever trick that will allow it to keep on winning indefinitely, whereas it has perhaps already lost everything.” [9]

In this quote we have a good critique on how the convergence of political economic agendas between capitalist and former socialist nations after the fall of the Berlin wall was based not on reasonable evaluations and commitment to an empirically superior system, but on self-delusion and false advertising. Industrial globalized capitalism is just one of innumerable possible economic systems for the people of the world, yet it is presented teleologically as a foregone conclusion, meanwhile it requires permanent maintenance of an atmosphere of imminent doom and threat.

If the technicians at Apple or Nokia, (and all the other cellphone producers, and the computer chip producers and the game unit producers, they are all in it together) had been motivated to create technologies which were really beneficial for all humanity right now and not just factoring in the potential deleterious effects of their design decisions as collateral damage, necessary in the war for market dominance, we might have seen the emergence of numerous divergent alternative forms of technology, since the materials needed for the smartphones, video games and computers we have today would have come at too high a price. Technology is not neutral, its values are inscribed in its hardware.

Electronics company technicians could be encouraged to create design solutions which would somehow foster social renewal in the countries where they live, but they are not., instead with all values heavily weighted with concerns over profitability, they allocate general prosperity the role of the greater social good, and export the problematic effects of new, urgent and extreme industrial demand somewhere far away and unknown.

Marshall McLuhan, lauded as the great prophet of the electronic age, always declaimed that he made no prognosis, but rather simply observed what was already happening. New technologies, such as nanochemistry do not bring about any Kuhnian paradigm shift either in scientific practice or in society. "It has never happened that a lab has shut down as a paradigm change in Kuhn's sense occurred. No equipment was thrown out, no people (least of all the clerks who produce the required lab equipment) were fired. The Kuhnian denial of the cumulative growth of knowledge is mistaken with respect to the technical side of science" [10] (On the other hand, a lot of consumer products have become obsolete as they were planned to- on the level of production, techniques have remained the same, only the fashion changes.) The last technical revolution was the first one, starting with the Gutenberg press and the steam engine and exponentially since the photograph. Though we in the elite may experience it as a Motley (ein buntes Gemisch) [11] our age is fundamentally not post-modern but rather hyper modern, with century-old industrial processes still humming along inside, albeit miniaturized.

The period we live in is properly not called post-industrial, but hyper-industrial. The industrial paradigm has not been surpassed. The self-proclaimed revolutions in the sphere of communications still utterly depend on industrial infrastructure. The industrial reality hums imperceptibly on in the background, in factories on the edges of the cities and in the great networks of tankers on the oceans. All this and more are 'assumed prerequisites' for the 'advanced society' in which we exist.

That the electricity which glows this screen-full of hopeful emancipatory meritocratic rhetoric is generated by turbines which have to be built in highly hegemonic systems all the way down, is something I wish to integrate in these very words. We need an epistemology generated from this symbiosis of structure and freedom.

Industrial paradigms persist everywhere in the creation of the hardware on which we generate our software Utopias. Many have heard recently of the sweatshop conditions of Chinese workers who assemble the iPad, how are we to perceive a utopia built on such dispositif? Yes the aspirations of humankind are great, they are also palliatives, rationalizations and apologia for the enormous human sacrifice such aspirations have always required. And after all the sacrifice, how much closer are we to that ideal?

Here I must claim with David Bloor's conservative Wittgenstein that "we don't need the present to contain the future, it is sufficient that it contains the past," [12] the future will be generated out of what we do with our past, not how we prepare or postulate or plan future scenarios. An unprecedentedly variegated technological reality is ready to emerge, will it ever get a chance?

DISCOMFORT DESIGN: CRITICAL REFLECTION THROUGH UNCOMFORTABLE PLAY

LINDSAY GRACE

Consider that uncomfortable moment in life when people discover a playful experience ceases to be worth playing. Just as an arm is broken on the playground, or a relationship can no longer be mended, there are explicit moments when art transgresses some unforeseen territory leaving us with fear of its potential. This paper explores the potential of taboo game design.

© Lindsay Grace 2011. Characters from *Match*, a Critical Gameplay computer game about matching races.

Introduction

Taboo is a construct that defines borders. It tells us where we can and cannot go. The social more is as much a looking glass to reflect on our values as it is a place to test our mettle. This paper seeks to explore how games offer unique critical experience through socially prohibited play. It simply seeks to discuss how play through taboo gameplay exposes that which we may not want to discuss. Taboo game experiences are more than just uncomfortable situations, they are opportunities in rhetoric. They punctuate an experience and offer opportunities for thoughtful reflection on social values.

Games are structured play, and it is their structure that reflects social value. The game of tag gives players two options, hunt or be hunted. So too, when designers of games construct play, they are defining a world and its options.

DEFINING TABOO AND THE MOMENT OF DISCOMFORT

Taboo is at its simplest, a strong social prohibition. It ranges from the distasteful to the unfathomable. The borders of the taboo are defined by social values which inevitably overlap, wax, wane and contradict themselves and the borders of those around them. They are somewhat like human emotion, as something clear to sense, but difficult to articulate beyond the tension of shame or ridicule (Browne 1984). It is as the old saying goes, people may not be able to define it, but they know it when they see

it. It is then appropriate that some of the most clear discussion of the taboo and its inherent ambiguity is provided by a text which declares itself as non-academic (Thody 1997), although written by an academic.

While taboo may not have a clear and fixed demarcation in cultural space, it is best defined by its attributes. Taboo is often ostracized and discomforting. When something is taboo, it is often put away, absconded with, or otherwise removed from a general experience. Almost upon release, taboo becomes fetishized or ridiculed (Browne 1984). As a result, taboo play is a very tricky area of research. While many people may have heard of the famed Custer's Revenge Atari 2600 Game (Hernández-Avila 2005), how many have played it? What prevents them from playing it? Is it the shame of seeking it, the fear of enjoyment or something even more dark?

The question of experience is exceedingly important. To know that something is taboo is to have taboo prescribed. To experience something taboo is to understand it. Designers of experience must understand, not merely be told. Likewise the power of taboo experiences are greatly reduced once they are reported instead of experienced. Returning to the example of Custer's Revenge, few people know much about the game's other experiences, only its taboo penultimate experience. This reduces the game from a complete experience to a caricature. One or two traits obscure all else. In so doing, we may even miss the most important element of the design – the moment of discomfort.

The moment of discomfort is the point at which play no longer feels right. It is like the rhetoric of speech. Players are lead down a path and follow intently when the experience is good. The moment of exceptionally high impact is when the player wants to follow, but fears what follows. It is even more impressive when that moment is of great conflict. Like the rhetoric of a powerful orator seeking to change your mind, the game may lead you in, have you nodding, and ultimately encourage you to agree to things you had not planned.

The moment of discomfort is the critical moment. It is the point where all things human meet. Players are at odds with their emotions, their social norms, their identity, and their understanding of what they believe is truth. Even the staunchest defendants of games as something outside of the everyday can reveal a moment when they have asked themselves if they should or should not be playing a certain way. This is the moment of discomfort. It is the moment when the player is brought back to the cerebral tension of reflection. It is the *wait a moment*, moment.

It is important to contextualize taboo and its moment of discomfort in a critical sense. It is not enough to ask why something is taboo. Instead, the important question is what about the moment of discomfort in taboo play makes it uncomfortable. Why does playing mean more than thinking? What actions in play drive the moment of discomfort and what borders of social appropriateness have been transgressed? It is also important to understand that the moment of discomfort is more than its moment. Just as a theatrical production or a political movement are more than just the few minutes of highlights, the moment of discomfort is a result of all game experiences within the subject game and the games that preceded it.

Sex and Recent History:

In the recent controversies of violence and video games in the United States Supreme Court one taboo reveals itself grandly. In the recent and widely publicized case involving the banning of violent games

sales to children, the majority opinion voiced by Justice Scalia indicate the dichotomy of sex and violence that are integral to American social norms. He writes “There is a critical difference, however, between obscenity laws and laws regulating violence in entertainment . . . obscenity had long been prohibited, see *Roth*, 354 U. S., at 484–485, and this experience had helped to shape certain generally accepted norms concerning expression related to sex. There is no similar history regarding expression related to violence.” (*Brown, Governor of California, et al. v. Entertainment Merchants Association et al.* 2011)

The fact that prohibition rests not in the malevolent destruction of another simulated being, but in the revealing of their natural parts or by participating in the act that created them is beyond telling. A game franchise such as *Grand Theft Auto* (Rock Star Games 1997) is not taboo in its acts of malice, but in its acts of giving pleasure. The game is arguably objectionable for its killing, but unsalable for a single act of sexual play, as evidenced by the prohibited sales of the then shocking hot coffee mod (DeVane and Squire 2008). The versions of the game sold with this programmed trap door, allowed players to unlock a portion of the game that afforded players the ability to simulate sexual intimacies with a non-player character. When discovered, hot-coffee mod containing versions of the software were pulled from retailer shelves. This was an enormous effort of prohibition.

On the continuum of distasteful to unfathomable, another commercial release sits neatly for American audiences. As the subject of more ridicule than objection, *BMX XXX* (Acclaim 2002) is a game that reveals that the moment of discomfort is not as simple as haphazardly grinding through taboo. The game is a fairly traditional, collection oriented extreme-sports title for off-road trick bikes. It rewards players by allowing them to see full motion video from the Scores chain of adult entertainment clubs. One reviewer put it succinctly, “aside from making the ‘groundbreaking’ move of featuring a lot of cursing and strippers, *BMX XXX* doesn’t do anything particularly well” (Gerstmann 2002).

What is most interesting here is that unlike *Grand Theft Auto’s* hot coffee mod, *BMX XXX* is not prohibited. While both games contain nudity, one must modify *Grand Theft Auto* to experience it. It is more likely that the moment of discomfort for *Grand Theft Auto* comes from its simulation. *BMX XXX* provides full motion, high fidelity images of sexual content in plain sight. *Grand Theft Auto* provides relatively low quality simulation of sexual acts. The moment of discomfort must then derive not from depiction, but from any variant of simulation. This is a distinct trait of games, as play is about acting, not merely watching.

Yet, the significance of simulation may not be that simple. Consider the *Dark Room Sex Game* (Collective 2009), which requires players to simulate sexual intercourse by shaking Wii remotes back and forth to rhythm. The game has no images, merely sound and motion. It is also, not generally subject to the same taboo response as *Grand Theft Auto*.

Grand Theft Auto’s moment of discomfort is largely about juxtaposition. Acts of violence repeatedly practiced, among a single sexual act is perhaps far more inciting than the act of simulation itself. This is important, as it indicates a much more complicated relationship to social discomfort. It is not merely that some Americans are uncomfortable with sexual simulations as play. It is that the juxtaposition of sex and violence is somehow taboo. Beyond that, it is the simulation of violence and the simulation of sex comingled that make taboo play. Other games that couple sexuality with violence, such as the *Dead or Alive 3* (Team Ninja 2002) tread in a much less taboo area.

Race and Historical Contexts

Juden Raus is an important historical game. It is not important for its mundane gameplay or mediocre design. It is important for its almost abysmal failure. It was an anti-Semitic game, so poorly designed that the Nazi SS audience purportedly rejected it (Morris-Friedman and Schädler 2003). It was considered too propagandist and in poor taste (Morris-Friedman and Schädler 2003).

The game, which roughly translates to Jew Out, requires players to move Jewish characters out of the city limits. For contemporary audiences, the entire scenario is taboo, yet for its audience, it was likewise dismissible. These types of games continue to illustrate the complications in constructing an effective moment of discomfort. It is not enough to be controversial. It is not enough to be bigoted. In the case of Juden Raus or BMX XXX, the designer does little to offer any type of rhetorical structure. Much of what needs to be known about the game is known in its first pitch. These games can be easily boiled down to moments of disrespect and cruel humor, while their experience is flatly structured. That is to say, the player learns nothing more from playing the game, than from hearing it. This is because if they play the game, they are not uncomfortable with its taboo. Or, if they are, there is also a part of them that wants to explore this taboo experience. Like fetish, they are lured by the experience and perhaps even seeking it.

This is an important aspect in constructing the moment of discomfort. While it is not wholly dependent on surprise, leading a player to a conclusion they did not expect is important. This is not a surprise, but it is an action in rhetoric. If properly constructed, a moment of discomfort is like well formed formal logic. If I as player enjoy A, and A implies B, why am I uncomfortable with B?

Ghettopoly (Chang 2003) is a game which touches a taboo topic in American culture. The game is a re-skinned Monopoly (Barbara 2007) based on the parodied experience of American ghettos. Railroads and community chests become gun shops and liquor stores. The game was sold in the popular Urban Outfitters chain, until political pressure removed it. It also resulted in an intellectual property lawsuit. Despite this chain of events, it's fundamentally unclear if the game really contains moments of discomfort. Players received much of what they expected. Simple attempts at humor at the expense of the misfortunes of ghetto life coupled with a pile of stereotype and racism.

The game and the ghetto it constructs are racial and economic. These are some of the United States' most sensitive topics. There are many spaces in race and economics that are fairly taboo for Americans. Yet, the game itself does not land squarely in social prohibition. Perhaps it is because Ghettopoly can be played at home, far away from the population it insults (Lardapide et al, 2010). The moment of discomfort for this game comes not from playing the game, but from where the game is played. Play the game on a city park bench in the middle of some of America's worst ghettos and the game is far more loaded with moments of discomfort. This is perhaps, why Juden Raus also failed. The moment of discomfort is as much about social space as it is designed experience.

Such claims are somewhat supported by the tension of Nazi paraphernalia for German audiences. As localization experts can attest, digital games for German audiences must remove Nazi allusion. This means turning the WWII Wolfenstein (Raven Software 2009) game into something other than a fight to kill Nazi soldiers. Here, the moment of discomfort is directly related to proximity - physical, historical, and social.

Social proximity is even more complicated when considering design source. While many players do not stop to ask who made the game they are playing, moments of discomfort, with their tension of reflection, drive players to these questions. Consider the board game *Life as a Blackman* (Sawyer, 1999). This game attempts to illustrate with a serious tone the complexities of achieving success as an African American male. The game was distributed by an independent publisher and developed by a young African American marketing professional. While it was never retailed at a chain like Urban Outfitters, it also never achieved the popularity of *Ghettopoly* nor the critical attention shared by similar games. Is it because a game by an African American, about African Americans lacks the tension of a game about African Americans by Taiwanese American, David Cheng (Ho and Mullen 2008)?

Given how infrequently players ask who designed a game, it may be that *Life as a Blackman* fails to be taboo enough to be fetishized? Unlike *Juden Raus*, *Life as a Blackman* had the support of some members of the African American community (Chadwick 2002). Unlike *Ghettopoly*, *Life as a Blackman* also did little to incite frustrations from insensitivity. Perhaps it is because the game was critical, but offered few moments of discomfort. The game instead, structures its rhetoric plainly and without tension. It does not say what is good or what is bad, it merely says what is. In doing so, it offers little opportunity for players to explore taboo around race. It is likely that *Life as a Blackman* is not uncomfortable because it asks players to explore no space we have not already explored. It asks players to think about many things, but it fails to create that jarring moment that forces critical thinking.

Conclusion

This reflection merely reveals the patterns in moments of discomfort. The important question still remains. What does a moment of discomfort do for critical reflection? The answer depends on the situation. Just as juxtaposition is a harmonic device in composition, or a rhetorical device in poetics, the moment of discomfort offers designers a highly effective opportunity to remind players to think. It is most powerful in its ability to rip a player from the rhythm of play into to the laboratory of thought. Like a child who falls off a bike, or the recipient of a great gift, the player is likely to ask – what happened? Sometimes the moment of discomfort will lead to positive revelations, other times they will be negative. It is most important to understand that it is an opportunity to effect players. It is an opportunity to exploit the rhetoric of play.

UNDERSTANDING THE ART PRACTICE OF CRITICAL GAMEPLAY DESIGNS

LINDSAY GRACE

The paper explores the recent growth in critical gameplay, an application of critical design to the production of computer games. This paper outlines play pedagogy and game rhetoric, relating critical design practices to the creation of computer games. It attempts to explain the art practice of critical game design, providing a brief digital game history and identifying prominent creative works in this relatively new space.

Introduction

In the maturation of a field, nothing is more telling than the creation of its discontents. Critical Gameplay games are the logical next step in the extension of games into a mature expressive medium. Critical games are political, social, expressive and even philosophical in their address.

These games reflect an art practice that is both intellectual and visceral. It serves as an experiment, eliciting player response and seeking to understand why these alternative ways to play had not been demonstrated previously. Each of the games pursues a single hypothesis with resolved specificity. The games ask questions about player values, gameplay heuristics and how we find entertainment. It recognizes the democracy of play, understanding that people not only like to play differently, but that playing differently expands the potential of games as expressive entertainment.

In design practices, there is a simple dichotomy that can be used to fundamentally describe the difference between affirmative design and critical gameplay design. This dichotomy divides designs by depth and breadth. Design depth is the continued exploration of familiar experiences. Design depth is the improvement of continued experiences, either incremental or dramatic. Design breadth is the exploration of unfamiliar experiences. First designs of any product or experience tend to offer breath, as they lightly explore a number of potentials. Later generation designs, seek deeper exploration of the same basic design concepts.

The trajectory of modern digital game design is largely rooted in deeper explorations of existing game verbs and mechanics (Fullerton, 2008). Under this model, comparatives evolve into superlatives. What was good gets a few models of better, and in time bests are created. Players do more shooting, or more jumping. If they are simulation games, designers may seek more realistic experiences in the pursuit of authenticity. A baseball game may incorporate a weather algorithm, or a car racing simulation may employ more complex physics. The central focus of this type of design is the continued affirmation of previous design decisions in an effort to make a better experience. This is the pattern of affirmative design (Dunne 2001).

The affirmative design model develops much like a plant grows. First an original experience sprouts into a full fledged game. Then subsequent designers employ algorithmic enhancements to that central concept, perhaps bifurcating one key notion or refactoring key elements like a fractal. The mechanics of moving through space move from 2D in Super Mario Brothers (Nintendo Creative 1985), to 3D in Super Mario 64 (Nintendo EAD 1996), and even add a 4th dimension (Blow 2008). It is often not until some element of a previous experience falls from these branches that a new and novel game rhizome evolves.

Consider the number of unexplored designs dismissed by employing this affirmative design model. The

decision tree for design begins with an assumption that what existed previously is worth continuing. Each car racing game, places the player in control of a car instead of the many other possibilities. Is it not equally possible to create an engaging play experience centered on maintaining the cars for another driver? Is it not possible to make an exciting experience where the player does not swing a bat or pitch a ball, but instead manipulates the weather algorithm to support their team?

Critical gameplay, analyzes, reflects and responds to affirmative design by demonstrating the possibility of play and interaction ignored by convention. It fills gaps, reminds players of other perspectives and engages imagination through a different practice in creativity.

If affirmative design is trajectory driven, Critical Gameplay is without trajectory. Critical gameplay is a practice in which players are asked to play differently. The goal of which is to expose players to experiences that highlight the relative absences in our daily gaming experiences.

Pedagogy and Rhetoric of Entertainment

To understand critical gameplay, one must understand how it intersects with pedagogy, entertainment and design practice.

Psychologists frequently identifying the value of play in delivering a safe space to practice skills and experiment (Millar 1968). In this framing, games are merely structured play spaces designed to meet specific goals. Where traditional games like Chess may analogize the battle field, playground games like tag may offer an opportunity to play both hunter and hunted (Crawford 1984). Digital play offers similar experiences. Digital games can simulate the experience of handling the soft suspension of a 1970's sedan or leading a squad of soldiers through a battlefield. The fundamental question for critical game research is what lessons are missing from the canon of gameplay experiences.

If games are inherently pedagogic, then there are several ways to investigate the lessons being taught. The first is to analyze common games, catalog the experience, and assess the lessons. This is the somewhat common practice of investigation into game content. It is well housed under the areas of game studies. Researchers seeking to understand violence in games, for example, have been actively involved in this type of cataloging research (Anderson 2004). The fundamental problem with this research is that it is highly content driven. It is inherently problematized by the act of mining content. Imagine the challenge of analyzing a literary canon by identifying the acts of violence in *The Lord of The Rings* (Tolkien 2004), *The Complete Works of Shakespeare* (Shakespeare 1996) and *Crime and Punishment* (Dostoyevsky and Gibian 1989).

Cataloging what exists does a better job of describing what is, than describing what is absent. If a person wants to add an addition to their house, it is nice to catalog the rooms they currently have, but it does nothing to speak toward the potential of the construction project. Cataloging is a retrospective activity, indicating what has been and is. If an addition is to be built, a person who understands the structures of homes and imagines the unrealized is hired. Building something new is not about cataloging; it is about knowing the catalog and realizing the new.

Another approach to investigating the lessons inherent in gameplay models is much more common among art and design. Instead of cataloging the experience and attempting to apply a scientific schema, artists and developers often create a collection of demonstrations. For critical games, these are functional experiences that not only highlight difference through contrast, they demonstrate other potentials. As literary authors or filmmakers, have previously exposed audiences to worlds they had forgotten how to imagine, game makers have the ability to re-imagine the way players play.

Secondly, while catalog approaches may provide exhaustive lists and somewhat compelling data, they often fail to offer solutions. Evidence merely reveals what exists, it does not provide resolutions. If we understand that games of violence are engaging, and we endeavor to inspire non-violent game play,

isn't it our responsibility to demonstrate how those non-violent games can work? More interestingly, if game design wants wider audiences, isn't it essential that wider play experiences be explored? Critical games are inherently pedagogic. They endeavor to teach by way of example.

For this reason, critical gameplay games are often not only pedagogic, they are also rhetorical. Critical gameplay games make an argument about what is engaging entertainment. They are often responsive, calling upon a convention and then either exploiting the convention's own assumptions, or inverting them. At their best, they demonstrate the magic of creativity, turning a simple cardboard box into a spaceship. They do so, by converting what can seem like a stale set of experiences into something for which there is no precedent. Or, they can remind designers and players of the discarded potential they dismissed. Bugs are turned into play, like a tin can substitutes for a soccer ball. A pile of rubble becomes a play space again.

The lessons in critical gameplay may not necessarily be desirable, just as varied audiences find offense in conventional play. Yet, critical gameplay is by definition critical. It is self-aware. As an explorer generally knows which way they plan to head, critical designers are directed by something other than the current trajectory. Affirmative design follows the line of logic laid before it. Critical design, sets an uncharted target. Both design approaches may not always land where they expect, but they have distinct paths.

The Design Practice:

Like many revolutions, the impetus of critical design is born from gaming discontent and relative outsiders. If game design is understood as travel down a straight road, critical gameplay design is the scenic route. The designers of critical gameplay are not seeking to continue the trajectory; they are offering another way to get somewhere else.

These game designers are providing new paths and new vehicles for travel. If the fundamental unit of game design is the game verb, then these designers are most commonly investigating new verbs. Many independent game developers have offered alternative verbs, but what distinguished critical gameplay is that these game verbs critique game standards themselves. Instead of merely offering the ability to do something players have not done before, critical gameplay games reference existing game verbs as critique. They provide notable play moments, that are most novel to games players and least notable to people who don't play games. Just as an 8 sided die is novel to some, and a table top RPG standard to others, the experience of critical gameplay discerns the familiar and the unfamiliar.

In some cases, the most efficacious player of a critical gameplay game is one that has not been trained in conventional play. It is this situation, the benefit of unfamiliarity that highlights the pedagogic content of games and the potential power of critical gameplay. Where a good gamer is typically understood as one who knows all the conventions of games, this inversion of power is a central pivot in critical gameplay. Critical gameplay games may be games that are easier to play for non-gamers than gamers. There can be little better evidence of the pedagogy of games.

Like a good experiment, most critical gameplay games are very specific in their address. They do not attempt to change everything about the way players play, but instead, they seek one or two points of investigation. Instead they may begin by questioning everything, but they end with one specific question.

Early Critical Gameplay Games:

Like many historical first, defining the earliest critical gameplay games is problematic. It could be argued that *Monopoly* (Hasbro 1990) is an early significant critical gameplay. As a rhetorical game design, it is inherently designed to teach the travesty of landlordship (Orbanes 2006). However, this example fails to appropriately reconceptualize conventional play. All lesson-oriented games are not critical gameplay.

it is important to understand that true critical gameplay is not only different, it is pedagogic and self reflective.

The space of contemporary digital games is perhaps an easier place to begin to identify appropriate critical gameplay. It is easier because it rests on an established canon of traditional and digital play. It is also easier because of documented exploration. These designers explicitly identify their designs as critical, providing the ever essential artistic intention. Much the way the writers of the theater of the absurd appropriately contextualized their work with both intention and a contemporary lens (Esslin 2009). Digital games were moved toward critical gameplay when the work of groups like Molle Industria and Faber Ludens started their success as early as 2004. Molle Industria creates games that are socio-political. Games such as Faith Fighter (Molle Industria, Faith Fighter 2010), which re-contextualizes religious conflict into a classic fighting game, laid the foundation for critical game design. Interestingly the game is an inversion of critical game design. Instead of seeking to critique play, the game serves as a critique of the social-political patterns which in Molle Industria's terms, are game like (Molle Industria). The group continues to create a variety of games that fuel wonderful tensions between digital play experience and socio-political issues. The Molle Industria games are essentially social-critical experiences, not play-critical experiences.

The Brazilian group at Faber Ludens has also been engaged in design work that is both political and playful. Unlike Molle Industria, which often produces playful tensions, Faber Ludens creates somewhat discomforting interactions. The group investigates concept designs like the Lead Years, a student project which was envisioned as an opportunity to provide interactive contextualization of historical torture in Brazil (Faber Ludens 2009).

Both groups apply the medium as an opportunity to critique societal characteristics, which lays a foundation for players to understand the notion that critical gameplay critiques game characteristics. While many of these games are critical, they too are not critical of the way our society chooses to play. They are more commonly critical of socio-political practices and their likeness to games, than the practices of play as political rhetoric.

Digital Games in Critical Gameplay:

The earliest intended critical games were created by the author of this paper in an ongoing project called the Critical Gameplay project and by Mary Flanagan. Flanagan published a book entitled Critical Play (Flanagan 2009), in which she takes a game studies oriented approach to cataloging critical play experiences. One of Flanagan's most notable contributions to the design of critical gameplay is a Giant Joystick (Flanagan, Giant Joystick 2006). In this work Flanagan offers a new play experience by a simple manipulation of input. She creates an Atari Joystick so large that one player cannot control it by themselves. Instead, multiple players must cooperate and communicate to accomplish the general goals of common, existing games. This is critical game design more in hardware, than game design. Giant Joystick does an essential job of reminding players, theorists, and designers of untapped potential.

The Critical Gameplay project has visited Asia, Europe, and locations in North and South America. The current collection of eight games is well documented through varied conference proceedings and book chapters (Grace 2010). These games are at the heart of critical gameplay practice. A few of the games include:

- Wait: a game that rewards players for balancing seeing with acting
- Bang!: a game that allows the player to kill other players, but by killing them the player must endure a long interruptive experience which forces the player to review the fictive history of their victim.

- **Black/White:** A game that thwarts the common proactive of stereotyping non-player characters by making threats and non-threats look the same, but act differently.

Recently a new breed of developers have begun incorporating critical gameplay practices into their designs. *One Chance* is a game by Awkward Silence (Awkward Silence Games 2010) that highlights and responds to the gameplay standard of multiple endings. The player has the opportunity to play this adventure game through the last few days of earth, but once players complete the game all options for other choices are eliminated. As the title suggests, there is but one chance to determine the game's resolution. It is this omission of second chances that is a direct critique of gameplay standards. If game design had taken a different trajectory, there would be nothing novel about committing players to a single resolution. Yet, it is this concept of only one chance that makes the game noteworthy.

Complimenting this experience is Zack Gage's *Lose/Lose*. As a self-declared art game, it endeavors to couple a play experience with real world consequence. When the player shoots an alien in the game, the game deletes a single, random file off of the host computer. If the player dies, the game deletes itself. It is this second property that strongly propels *Lose/Lose* (Gage 2009) into the critical game space. Most games have a pay to stay or learn to play algorithm. If player fails to learn and successfully employ the game verbs they are either subject to game end or required to deposit more money. Yet, *Lose/Lose* inverts this relationship by eliminating itself. Failing to play the game well, saves the player from harm. *One Chance* and *Lose/Lose* are obvious in their pursuit and not very subtle in their execution. They are big in their presentation, but small in continued potential. Other critical games offer more potential for scale and provide a deeper experience.

A House in California (Elliot 2010) is a nostalgic game. It is a game that is personal in its origin, but universal in its experience. Designed as a kind of homage to Roberta and Ken Williams' *Mystery House* (On-Line Systems 1980) the game becomes critical at its game verbs. If one evaluates the dominant verbs of typical text and point-click adventures, the verbs are highly physical. The players are asked to act upon the world by taking, leaving, attacking, and others. Elliot provides new verbs, in a standard list of look, remember, forget, play, learn and catch. Remember and forget are much like a cerebral take and leave. Learn is a deeper verb, offering something beyond remembering. These three verbs, remember, forget and learn are at the heart of this critical gameplay experience. Consider how few games have ever afforded the player these actions. Then consider the rarity of a verb which conceptually, but not ordinarily builds on the other. It is common to ask a player to punch then kick, but to punch through kicking (which is not the same as punching and kicking simultaneously) is rare. So the player is left with an important ambiguity. If I can remember and forget, what does it mean to learn? An even more important question also arises – why haven't other games employed these verbs?

The opportunity for critical play to make rhetorical claims has not gone unnoticed. *Arizona Justice* is a game designed (Social Activist Games 2010) as political rhetoric. The game is a fairly standard, small serious game about a political controversy in the United States. The game employs an aesthetic and similar mechanics of Nintendo Wii's *Mii Match* (Nintendo EAD 2006). However, it is designed to critique the expected nature of an Arizona state law allowing authorities to question people who look like they may be illegal immigrants. The player must determine which players are illegal immigrants as they parade down the screen. The game's primary game verb is ostensibly point and click to identify illegal immigrants. Yet, more careful analysis reveals that the game's verb is stereotype and discriminate. While immigrants in the game can be any color, immigrants in the game are disproportionately non-white. The player is encouraged toward clicking on non-white non-player characters, driving the player toward the patterns that the game critiques in opposition.

Critical gameplay design continues, although it is clearly in its infancy. It is the authors hope that game designers embrace its ability to expand the experiences of play and potential to impart new rhetoric.

NEURAL GHOSTS AND THE FOCUS OF ATTENTION

Jane Grant

In this paper I will discuss the phenomena of cortical sonic hallucination in conjunction with the new artwork *Ghost*.

Ghost, Raster Plot, Jane Grant, 2011.

Consciousness as attention to memory is a term that neuroscientist Eugene Izhikevich uses to describe a phenomenon in which the cortex re-lives or re-visits a specific pattern of neural activity in the absence of sensory information. The model brain or cortex, deprived of stimulation, journeys around its own temporal architectures conjuring past ‘experiences’ or ‘memories’, pulling them into the present. Evidence that these pathways continue to be re-visited once stimulation occurs again is compelling.

Referring to recent research in developing the sonic artwork *Ghost*, and an earlier work: *The Fragmented Orchestra*, all of which have at their core the Spike Neuronal Network model of Eugene Izhikevich, I will discuss the phenomena of ‘sonic ghosts’, a term I have used to describe the buffering up of the neural past within the neural present.

What we experience as consciousness occurs at many different cortical locations and timescales. In the paper ‘Polychronization: Computation with Spikes’, [1] Izhikevich discusses one of the simulated, anatomically realistic models of 100,000 cortical spiking neurons that he and his team have created. These networks of spiking neurons form polychronous (multiple or many times) groups, which fire with ‘millisecond precision’. The connection strength between pairs and groups of neurons is intricately dependent upon the difference between spike arrival times, the phenomenon known as Spike Timing Dependent Plasticity (STDP). The groups of firing neurons are ‘time locked but not synchronous’ [1] and that it is the destination of the spiking and not the activation that gives rise to the complexity of the model. Izhikevich states that these time-based clusters or groups across the cortex, give rise to the beginning of ‘simple thought and memory.’

These groups are interesting as they form as a result of STDP, not as a consequence of anatomical clustering, emerging from the ‘dynamics of the connectivity between the neurons’. The polychronous

groups, because of this continual formation, grow and then disappear, although some 'live' and become more permanent in the neuronal model.

Izhikevich likens the network of polychronous groups to the immune system in which we appear to have antibodies for all possible antigens, 'even those that do not exist on earth'. He also proposes that these groups contain all possible variation of both thought that is, and thought that is to come – all potential manifestation of human cognition.

A major significance of polychronous groups is that they may represent memories or experience. The neuronal model becomes autonomous, self-activating once a certain threshold is achieved. The model devoid of any stimulation or articulate input generates random memories or experiences not associated with any previous input. The network has exceptional capacity for memory and it is this memory that is re-visited when external stimulus is not present. Once the network exceeds a particular threshold, an activation of groups occurs. These groups represent an external stimulus which go on to trigger other groups so that the number of internally stimulated groups are equivalent to the number of groups activated when externally stimulated. Izhikevich calls this 'the focus of attention.' [1] Therefore when external stimulus is not present, the neuronal model, driven by noisy currents, re-visits some of these firing clusters, following the formation of pathways previously established through external and internal stimulation. In a sense it could be said, that the cortex re-lives previous experiences.

"If the size of the network exceeds a certain threshold, a random activation of a few groups representing a previously seen stimulus may activate other groups representing the same stimulus so that the total number of activated groups is comparable to the number of activated groups that occurs when the stimulus is actually present and it is the focus of attention." [1]

"One can say that the network 'thinks' of the stimulus, that is, it pays attention to the memory of the stimulus. Such 'thinking' resembles 'experiencing' the stimulus. A sequence of spontaneous activations corresponding to one stimulus, then another, and so on may be related to the stream of primary (perceptual or sensory) consciousness." [1]

These streams of primary, perceptual and sensory consciousness are the temporal architectures of the brain, fleeting structures built of time. The structures are remarkable, as the neuronal firing events that the stimulus triggers remain, albeit temporarily, despite that they are no longer being physically, sensorially activated.

The aim of my research is to sonify the events that occur within the cortical structures. Their temporality and complexity are fascinating, in terms of time, the precise, but very fleeting nature of these events, are coupled with the exactitude of the millisecond. Furthermore, each firing event has the potential of infinite dimensionality, complexity in process, thought in the moment of becoming.

The Ganzfeld 'entire or total field' experiment sought to explore extra-sensory perception using mild sensory deprivation, white light and noise, in order to negate defined external stimulation. Regardless of the controversial findings in the field of parapsychology, what became apparent, was that the un-stimulated or sensorially deprived visual cortex begins to conjure vague images or impressions of scenes.

Age related macular degeneration consists of loss of vision occurring at the centre of the visual field. This lack of visual information causes blurred vision and eventually the loss of vision itself. In many

cases it also results in the phenomenon of hallucination ranging from mild to impressively articulate. These hallucinations are thought to be caused by the absence of continual visual information relayed from the retina through to the brain, the brain 'filling in' for the sensory information it lacks. In Ganzfeld, whilst every care is taken to deprive the brain of any stimulus; sound, vision and, of course, movement, the brain is never silent. Another more recent study in short-term sensory deprivation found that people not normally prone to hallucination experienced delusions and apparitions during the short period of deprivation. The researchers, from University College, London believe that the hallucinations are produced by a phenomenon called 'faulty source monitoring;' in that 'the brain misidentifies the source of it's own thoughts as arising outside the body.' [2]

The brain, as we have seen from Izhikevich's model, despite the stimulus being removed, creates its own activity, re-visits past experiences, pulling them into the context of the present.

In *Ghost*, eight speakers, eight microphones and a computer are connected to form a 'memory embedded' network of neurons. Sounds have been implanted into the cortex beforehand to provide the system with a buffer or 'memory'. Once installed, live, ambient or performed sounds in the gallery will stimulate artificial neurons, modelled in the computer to fire, sending tiny fragments of sound from the eight microphones to the speakers. When these sounds fail to reach a certain threshold the cortex will journey around its own architecture, re-visiting older, established pathways, using its 'memory' as buoyancy when external stimulus dies away. This memory is its own internal noise, its earliest and primary stimulation. These sounds will be heard as 'sonic ghosts,' a term I have used to describe internal or endogenous noise embedded in the cortex, which reoccurs when the external stimulation is low or not present in the gallery space.

Ghost will reconfigure internal and external sounds causing a temporal and sonic overlapping of the neural past within the neural present, a rupture in the flow of sensory and endogenous information. As the external sonic events occur these will be drawn in to the cortex building an ever-increasing bed of experiences from which to compose.

One of the initial phases of this model was *The Fragmented Orchestra*, where groups of spiking neurons formed polychronous groups allowing a rich and dynamic model of firing activity in the cortex.

"*The Fragmented Orchestra* is a vast distributed sonic structure created by Jane Grant, John Matthias and Nick Ryan. It was installed in the United Kingdom between December 2008 and February 2009. It consisted of 24 fixed geographical locations, including FACT, Liverpool, University of Plymouth, Landscope Primary School, Devon, The National Portrait Gallery, London, Millennium Stadium, Cardiff and Kielder Observatory, Northumberland. At each of the locations, a 'soundbox' was installed, which consisted of a microphone, a small computer connected to the internet and a Feonic 'drive', a device that transmits audio through resonating architectural surfaces. Sound made in the spaces was transmitted across the internet to a server computer in the FACT gallery. In this computer, we ran an artificial neuronal network, an adaptation of the Izhikevich's recently developed non-linear integrate and fire model that incorporates spatial 'axonal delays' between synapses and a spike-timing-dependent plasticity algorithm, which causes the synaptic strengths between neurons to become updated as a function of the differences in signal arrival times." [3]

In *Ghost*, temporal and topological memories within the cortex, in conjunction with the phenomena of cortical, sonic hallucination are explored. Further research is needed to monitor the buffering up of the

neural past within the neural present in conjunction with STDP. A computer model that creates statistical data and visualization of what exactly is taking place will be developed over the coming year to explore what might be called the thickening of experience. The infinite complexity of how this cortex might perceive what we call experience is extraordinary, a folding in of external and internal articulation, double looped, networks of earlier stimulation extending into the now, sensory architectures building into an endogenous cortical construction of time, the 'sonic ghosts' being the hallucination that the audience hears in the absence of stimulation. It is the crossing of the threshold of the internal to the external and back again which translates milliseconds of neuronal activity into moments of sound dispersed across timescales and geographies and the minute spaces of the brain.

MEDIA ART EXPLORES IMAGE HISTORIES: NEW TOOLS FOR OUR FIELD

Oliver Grau

The starting point of the following comparisons is the visual manifesto of knowledge, L'Academie des Sciences et des Beaux-Arts, Sebastien Le Clerc created in 1698; here is a print from the Göttinger Graphic Collection. L'Academie can be described as summa of the grand project of mathematizing nature as propagated by Descartes and Newton.

This digitization of a print, which can be magnified some sixteen thousand times, enables new access to the 'dead medium' of graphic prints and allows us to discover details that are barely recognizable in the original, for, to paraphrase Wölflin, "one only looks at for what one is able to see," in order to make new questions and answers possible.

Nested against a background of magnificent architecture, Le Clerc presents the grand spectrum of arts and sciences disciplines: mathematics, mechanics, physics, astronomy, music, anatomy, and philosophy are clearly recognizable. A great deal has been written about this work; I focus on the visual media, which commentators so far have ignored. Interestingly, today as we seek to understand the revolution concerning our visual perception, it is these visual media in Le Clerc's picture that have been picked up by artists.

When we zoom into the image, we see that Le Clerc's summa is also a collection of the optical media of his time, like in a burning mirror: the physiological basis of spatial vision is represented as well as central perspective, with which this drawing aid also refers to the vellum used by Dürer.

ANAMORPHOSIS

The anamorphosis, described by Lacan as the "reversal of central perspective," came to the West from China in the fifteenth century and subsequently developed into a variety of sub-techniques. Severely distorted objects could either be transformed into a recognisable image by using a cylindrical mirror or by viewing them from an acute angle. These images, which could only be experienced, so to speak, interACTIVELY could be regarded as precursors of today's processual images.

For years William Kentridge, one of the most known artists of our time, has been working around the subject of vision. Even historic image media, like the mirror anamorphosis, made its way into his contemporary media art. In 2007 he created a hybrid that had not existed before in the media history of seeing: using his eight minute short *What Will Come (Has Already Come)* he links a hand-drawn animation film with the anamorphosis, which appears connected now for the first time with moving images.

To get an accurate picture of what the distorted pictorial metaphors contain, Kentridge lets us use a metal cylindrical mirror: newsreel images of a colonial war Fascist Italy fought in 1935/1936 in Ethiopia. Kentridge, who comes from a South African Jewish family, fuses descriptions of the war with poetically

floating projections of memories to create a parable about violence — a revolving carousel of images like a visual maelstrom with the power to pull the observer in.

Kentridge gives us a bitter truth in a sugary pill: “Those who cannot remember the past are condemned to repeat it” (George Santayana), a pleasurable deception that we experience naively and at the same time knowingly. Kentridge’s video is not a film in terms of any time sequence, but rather a collage with, in part, hermetic elements, which overlap and are used by Kentridge as the vehicles of ambivalent, secret, even magical messages; perhaps inspired by Baltrusaitis’s description of the uses of anamorphosis in the course of history.

Kentridge, as we know, photographs different stages of his charcoal drawings for the animation, that is, he adds new details and erases others, working on the relatively small number of twenty to forty drawings per film, and what remains represents the final version of a scene — over a layer of drawings that have been re-worked several times. Kentridge expands the anamorphosis as a medium in two ways: firstly, he draws 'distortedly' with the aid of a cylindrical mirror after the classic manner of anamorphic depictions to obtain the desired proportions. Secondly, with his innovative crossing of anamorphosis and animation Kentridge also expands the possibilities of film: what Gunning claimed for Kentridge’s *Stereoskop* in 2001 — a “running metamorphosis” — is clearly ramped up in *What Will Come*. Kentridge not only succeeds in creating a space of distance and of thought through citing the historical anamorphosis; he also develops a media hybrid, which challenges the observer to become aware of their own active role in the production of images. In order to experience the complex, dynamic, and heterogeneous image space, the observer must become physically active — consequently, Kentridge exposes the iconicity of the image, if you like, which only arises through perception — in this case, in the anamorphic process.

It is not surprising that Kentridge develops his artistic approach in a time where the world of images around us is changing faster than ever before: images are advancing into new domains, to new private platforms like YouTube; Flickr, with its billions uploads; or Facebook, that has received his 700 millionth member and is now the largest image archive in the world. Television became a zappy field of thousands of channels; now in 3D — and 3D experiences as we know are having a renaissance in Cinema as well — here you see previous booms of 3D in cinema's history. Large projection screens are invading our cities, buildings' surfaces meld ever more often with moving images, so that the old dream of talking architecture gets a new arsenal of options; cell phones transmit movies in real time; and *Google StreetView* and *Google Earth* step up the concepts of panoramic image spaces including Satellite views, for example of our Center for Image Science in *Göttweig*.

All this, let's say virtualization, requires a so far unknown material base: Google runs, for example, one million servers in a dozen of countries, even on the ocean, and processes twenty four Peta Byte of user generated data per day. The several million people who died in the race for conflict minerals — here you see a new one hundred Gigaheart IMB Graph Chip — did not even receive a monument of the unknown victim. Digital images became ubiquitous and key tools within the global reorganization of work, but these transformations have hit society to a large extent unprepared. I will not go deeper into that but some results of our research you can find in a newly published volume by MIT Press.

In our most recent present artists venture in a reflective manner towards new measurements of the complex status of seeing and creating images. Images' historical development between innovation, reflection and iconoclasm reaches in the 21st century a new level of global complexity. In the "mine of media history" and the history of image techniques new thinking spaces (Denkraum) are created through new interfaces, displays, hard- and software configurations, often engaging viewers in a form of playful, creative combination. The Media Arts landscape of recent years is being increasingly seized by a phenomenon which has yet not received any significant research, classification or analysis: the use of historic media configurations as an integrated part of contemporary media art installations. There are internationally renowned artists today who create optical experiments, panoramas, phantasmagoria, perspective theaters, camera obscura, anamorphoses, magic lanterns, etc. By reinterpreting old optical media they contextualize our digital image revolution, create distance and with that thinking spaces.

PEEP SHOW

Lynn Hershman provided us with an early glimpse in 1993 with *A Room of One's Own*, a voyeuristic, 'peep-show-like-look' into a miniature bedroom. Through a periscope at eye level on a large black box, the observer directs the progress of the installation interactively by eye movements, by the gaze. This set-up allows Hershman to use the installation, which connects the design of a modern-day sex peep-show with its historic forerunners; to interrogate forcefully the tense, even violent relationship between the female model depicted inside and the presumingly male observer looking in.

The contemporary peep-show, which unites illusion and the quick and furtive look, could perhaps stand for the male, but increasingly also the female, gazing at pornography on the Net; statistically the most frequent use of the Internet, but for academic cultural disciplines still by-and-large a taboo.

CAMERA OBSCURA

In a walk-in "Camera Obscura for Danube" on a cable ferry, installed in 2004 by Olafur Eliasson, passengers see the cultural landscape outside going past on large screens. Although looking like video displays, they employ no electronics whatsoever. At the centre of Eliasson's artistic intention are the users of the ferry, the observers who find themselves inside a machine for seeing that is also a time machine. We know that art and image history owes much to the camera obscura and since Cray there is no need to add anything further including the walk-in variety. Like the visitors at the fairs of yesteryear, the present-day passengers are amazed at how the images of the surroundings outside are generated and this fosters awareness of the Wachau cultural landscape and thus also the dimension of time. A long time aesthetically designed space becomes through Eliasson's modest, but highly precise, intervention acute.

PANORAMA

The panorama, the illusionistic medium par excellence, has enjoyed a revival in media art over the last twenty years in many installations. Here you see world wide exhibited art works from the early nineties by Maurice Benayoun, Michael Naimark, Luc Courchesne and Jeffrey Shaw and their teams; Shaw has been working for decades with immersion and has been using the term Panorama for about fifteen years now. Here, we have another recent interactive, real-time example featuring Melbourne, *Place-*

Urbanity. Users can explore fifteen panoramic scenes of different urban districts that are each home to a specific immigrant or ethnic community.

Whether consciously or unconsciously these artists, as we know today, all refer back to a historic ancestor in the history of art and the media: the 1787 patented panorama. Originally conceived as a new tool of visualization for military reconnaissance, Robert Barker's invention with its circular perspective soon became a mass medium that reached several hundred million people. In a manner reminiscent of modern fears of simulator sickness, the panorama was criticized around 1800 mainly for psychological reasons. It was argued that the illusion could result in an inability to perceive reality and the military leaders of France and England, Napoleon and Lord Nelson, soon realized the panorama's potential as a medium for propaganda.

The amalgamation of traditional Japanese culture – like Zen, Kabuki or Sensui ink painting – with the digital has for years been the goal of Kyoto based Professor Naoko Tosa. Here you see her *Interactive Zen Garden*, which makes us reflect on the comparison of Digital Culture with our traditions, so that conscious ZEN practice, the meditation reappears in contemporary culture – but her discourse between tradition and technology is now driving panoramas history into an unheard dimension. For the upcoming world EXPO 2012 in Korea, Tosa is planning to bring the lineage of huge impressive-immersive pavilions you find in most world fairs with the latest technology to a new level. Tosa's installation *Under Water Sansui with Four Gods* will transpose visitors into immersive 360° projections; a gigantic 250m long landscape wall-panorama, composed of projections of dynamic Sansui ink paintings, each measuring 20m high. Additionally, people walk under enormous flying dragons, which dominate the ceiling, consisting of a gigantic LED display, 23m wide and as long as 2 and a half football fields – imagine!

SHADOW PLAY

The enormous worldwide and especially European tradition of Shadow Play, has inspired Rafael Lozano-Hemmer, one of the most well-known contemporary artists. Indeed, Hemmer has written that he was inspired by Samuel van Hoogstraten's 1675 published *Shadow Dance*, from his book *Inleiding tot de Hogeschool der Schilderkunst*. For over a decade, Hemmer has created multifaceted versions of an interactive shadow theatre through a combination of the spatial relationships of visitors. Recently this development culminated in the installation *Sustained Coincidence - Subsculpture 8*, which forms overlapping shadows of the interactors by reactive light bulbs.

LATERNA MAGICA/PHANTASMAGORIA

In the case of the laterna magica, as I'm sure you know, we come to 'the' projection technology of the modern era, forerunner of cinematography, and — if you like — the video projector in this lecture hall which provides our images.

It is a remarkable fact that since the beginning of the new millennium the most extreme variant of the laterna magica is staging a comeback: the phantasmagoria, an image machine developed after the French Revolution, nowadays reflected by artists like Zoe Beloff, with her *Influencing Machine*; Rosângela Rennó, here with her 2004 *Experiencing Cinema*; Toni Oursler's *Influence Machine*; or works by Gary Hill or Laurie Anderson; all artists who do not have to fear competition with artists using

traditional art media, still preferred by the art market.

Not only that, but the Phantasmagoria has also reappeared in pop-culture; recent and spectacular examples are projections of ghosts in the Hollywood productions *The Magician* and *Inglourious Basterds*. In the latter, the freshly murdered owner of a Paris cinema – whose parents were also killed by the Nazis – appears in a burning cinema to the trapped people – all of them top Nazis – as a large projection; first on the cinema screen, then in the classic phantasmagoric manner on fire smoke, here as avenging angel.

A new variant of this media-art historic lineage was created in just the last few years by Jeffrey Shaw and Sarah Kenderdine with *UNMAKEABLELOVE* in their cybernetic theatre *Re-Actor*. *Re-Actor* is a real time augmented reality application using torch-interfaces to reveal a world of thirty humans, inspired by Samuel Beckett's *The Lost Ones*, though of course its allusions draw much wider to the human tragedies of the last century. Shaw himself mentions as an inspiration early cinema history, quote: “the myriad of extraordinary devices like the Lumiere Brothers Photorama, the Cyclorama, Cosmorama, Kineorama, Neorama, Uranorama [..]” etc. Here, they combine interaction not with a 3D humanoid but phantasmagoric figures, who seem to move in a dark space or even a prison camp formed by a hexagon of six rear-projected silver screens for passive stereo viewing. This results in the most powerful re-appearance of the phantasmagoria: a deprivation, maybe even an icon for we human's in a WEB 2.0 world of 'connected isolation.'

Our Archives of Digital Art count many Media Art works, which are, for example, part of the history of immersion, a recently recognised phenomenon that can be traced through almost the entire history of art in the West. History has shown that there is cross-fertilization between large-scale spaces of illusion that fully integrate the human body (360° frescoes, the panorama, Stereopticon, Cinéorama, IMAX cinemas, or the CAVEs) and small-scale images positioned immediately in front of the eyes (peep-shows of the 17th century, stereoscopes, stereoscopic television, Sensorama, or HMDs).

CONCLUSION

Against the backdrop of the image revolution, today renowned artists are engaged in an ongoing endeavor to gauge the spectra of how images act as well as the continual transformation of how we see. Artists investigate how our gaze can be focused and concentrated, or diverted and dispersed; they analyze how we can be mesmerized, perhaps even ensnared, as well as how we can extricate ourselves from this clasp. Based on impulses from the history of perception, media artists today develop emancipatory strategies. This is in order to characterize how the gaze is constituted and to outline the inter-linked quantities of fiction and that which we call reality; between illusion and that which we could term 'pure seeing,' that acts in an enlightened and media-competent manner and exists at most as an abstract goal.

In the new millennium some of the important artifacts from the history of image machines are being mined for the artistic experiments of contemporary art: the magic lanterns and their offspring, the phantasmagorias, are being revived to produce magical, psychological, and eerie effects and atmosphere, and the wide open views of the vedute and panoramas are also making a comeback. Media artists frequently vary them, and reflect and recombine them in the interests of the viewer. The rectified images of the anamorphoses are again being used to convey political messages. What all these image machines have in common is that they are not being utilized for wistfully nostalgic historicism or for one

of the models of the evolution and advance of media development; rather, the artists are investigating the conditions and strategies of generating images and how these are perceived.

Reflection on art, on the aesthetic experience and the act of seeing in general, requires, as Cassirer, Warburg, Panofsky, Merleau Ponty and recently Hal Foster pointed out, DISTANCE. Often experimentally, the artists create new spaces for thought, not only to reflect on image media of the past, but more — it is to be hoped — on the circumstance that the fusion of digital technology with the apparatuses from art and media history will succeed in tracking down, arresting, and rendering comprehensible a piece of the present that has slipped from our grasp due to the distanced position we have taken up.

As we know, mass communication via audio-visual media is regarded as an achievement of the last century, yet the contemporary forms and formations are the result of complex historical processes that go back much further in time to the early modern age; already by the mid nineteenth century technologies, distribution methods, and configurations had developed that catered for mass audiences. Media Art, by definition, is, as we know, a relative term that has experienced transformation over time and currently counts digital media art as its newest representative. Today, film, cinema, and even television are regarded as 'old' media, because the image industries offer new media generations at ever shorter intervals — with the modern and post-modern eras quasi in the rear-view mirror. Although the dominant status of these media ensure that they are increasingly involved in creating collective 'reality' and are therefore rarely the subject of public inquiry or debate themselves, slowly but surely their supremacy is waning and the pre-history of the visual mass culture of the twentieth and twenty-first century is surfacing.

All this sounds like redefining images in their historical dimension and approaches of comparison, which go along with that, are based on the insight that images act diachronic, within a historical evolution and not function simply without reference. Image Science, or Bildwissenschaft, now allows us to write the history of the evolution of visual media, from peep-show to panorama, anamorphosis, stereoscope, magic lantern, films with odors and colours, cinéorama, IMAX, and the virtual image spaces of computers. It is, let me underscore, an evolution with breaks and detours; however, all its stages are distinguished by a relationship between art, science, image and media.

Let me now, in the second part, address elements of the development of media art research and scientific tool building our field needs.

We know that media artists today are shaping highly disparate areas, like time based installation art, telepresence art, genetic and bio art, robotics, Net Art, and space art; experimenting with nanotechnology, artificial or A-life art; creating virtual agents and avatars, mixed realities, and database-supported art. These artworks both represent and reflect the revolutionary development that the image has undergone over the past years.

Over the last forty years Media Art has evolved into a vivid contemporary factor, Digital Art became 'the art of our time' but has still 'not arrived' in the core cultural institutions of our societies. Although there are well attended festivals worldwide, funded collaborative projects, discussion forums and database documentation projects, Media Art is still rarely collected by museums, not supported within the mainframe of art history and nearly inaccessible for the non north-western public and their scholars.

Even if today Media Art, with its multifarious potential of expression and visualization, which thematizes

complex challenges of our societies like globalization, knowledge explosion, genetic engineering, ecological crises etc. quantitatively is dominating the art schools – Media Art is almost ignored by most museums, the acquisition and maintenance can still not compete with traditional art media. Thus, due to the fast changes in storage media, works that originated approximately ten years ago can normally not be shown anymore. It is no exaggeration to state that we face the TOTAL LOSS OF AN ART FORM from the early times of our postindustrial-digital societies.

Media Art therefore needs – as most of us know – as many bridges into our societies as possible: conferences, text repositories, database projects developing collective documentation and preservation strategies – new thesauri and new curricula for the next generation of teachers, artists and collectors.

Image Science and Media Studies help understand the function of today's image worlds in their importance for building and forming societies. With the history of illusion and immersion, the history of artificial life or the tradition of telepresence for example, Image Science offers sub-histories of the present image revolutions. Image Science, or Bildwissenschaft, is an open field that engages equally with what lies between the images and with the new perspectives resulting from interplay with neuroscience, psychology, philosophy, emotions research and other disciplines. Image Science might be considered as a reservoir in which contemporary processes are embedded, like an anthropologic narration, but as well the 'political battleground,' where the clash of images is analyzed.

Already in the 90s it became clear, that Media Art Research is spread over many disciplines and more and more the need became urgent to give it some common ground. That's why Media Art Histories held its first international Conference *Refresh*, for which I served as its chair. In 2005, through a collective process, involving thirty advisors and a dozen session chairs, co-ordinating meanwhile far more than a thousand papers, in co-operation with Leonardo and New Media Centre, *Refresh* represented the wide array of nineteen disciplines involved in the rapidly emerging field of Media Art Histories – some of the results you can find in an anthology from MIT Press. The good news is, through the success of *re:place* 2007, in Berlin's House of World Cultures, the conference series could be established, so that after Melbourne 2009, Liverpool later in September and Riga 2013 are on their way – so you are invited to show up there too.

Building Bridges for Media Art means also to further the establishment of new curricula, as we developed the first international Master of Arts in Media Art Histories – with faculty members like Erkki Huh-tamo, Lev Manovich, Christiane Paul and Sean Cubitt – which deals also with the practice and expertise in Curation, Collecting, Preserving and Archiving of Media Arts. It's a Masters for media art's working professionals, the average student is thirty five years old and they come now from five continents; in the meantime a Facebook forum with more than 2900 members also exists.

The field of Media Art Histories, which overlaps with image science, examines the sub-histories of media art: paradigms like artificial life/Automata or telepresence, the history of panoramic perception and it's knowledge with the related history of immersion and the history of projection for example. So, the method of comparison, which is based on the insight that images act diachronic (but not teleological) within a historical evolution –with detours and contradictions, in the sense of Gould, but never, as Warburg pointed out, function without reference – is a central pre-condition to deal with media art. Image science is based on three pre-conditions: 1. definition of the object, 2. setup of an image archive and 3. familiarity with a large quantity of images. Analogies or fundamental innovations in contemporary phenomena can be discerned through historical comparison, allowing us to differentiate and to distance

ourselves from the phenomenon, so archives became again an integral element in Media Art Research and Image Science.

We know that Darwin's work *The Expression of the Emotions* inspired Warburg's *Mnemosyne* image atlas of 1929, which remained a fragment. The Atlas tracks image citations of individual poses and forms across media and, most significantly, independent from the level of art niveau or genre. We may even say, that Warburg redefined art history as medial bridge building by including many forms of images.

Although taking a different approach, the history of image databases should also mention André Malraux with his *museé imaginaire*. Now, we are witnessing the birth of the virtual museum as a key project for the Digital Humanities.

But let us watch for a moment beyond the Humanities.

In the natural sciences during the last decade large collective projects could address new research goals as in Astronomy, the 'Virtual Observatory' compiles centuries worth of celestial observations; global warming is understood with projects like the Millenium Ecosystem Assessment, at a detail never before calculable, and the Human Genome Project has already become legend. So far, unknown collective, international and sustainable structures enable science to give answers to complex problems.

Comparable with natural sciences, digital media and networked research catapult the humanities within reach of new and essential research tools. Linux and Wikipedia might be seen as a glimpse what can be possible, and what we need are collective documentation and preservation tools for media art, or, even better tools, which can manage an entire history of visual media and their human reception by means of thousands of sources. These themes and needs express, in regard to image revolution, key questions for the humanities today.

In 1999 we established at Humboldt University the first online media art documentation, the Database of Virtual Art. As pioneer, it has been documenting – in cooperation with renowned media artists, researchers and institutions – the last decades of digital installation art, as a collective open source project. Since today's digital artworks are processual, ephemeral, interactive, multimedial, and fundamentally context dependent, because of their different structure, they required a modified, we called it an "expanded concept of documentation."

As probably the most complex media art resource available online with several thousand documents and their technical data, more than two thousand listed articles and a survey of seven hundred and fifty institutions of media art, the database became a platform for information and communication. The system allows artists and experts to upload their information and the DVA relies on its advisory board represented by Christiane Paul, Roy Ascott or Jorge La Ferla. Let me clarify that the DVA represents the scientific selection of approximately five hundred artists of approximately five thousand evaluated artists. The policy, whether an artist is qualified to become a member, is, "the number of exhibitions, publications (at least five), awards and public presentations; we also ascribe high importance to artistic inventions like innovative interfaces, displays or software."

The main challenge that existed, and still exists, during the last fifteen years is the establishment, maintenance and advancement of the social corpus, consisting of hundreds of living individuals: artists, whose affiliation is not automatically assumed since the DVA is not defined like other projects, who focus on a festival or a collection.

In addition to searches of themes, Media Art documentation should also admit questions of gender, track the movement of technical staff from lab to lab, technical inventions pertaining to art, the destinations of public and private funds allocated to research. The hybrid character of media art requires a shift of the paradigm towards an orientation of process and context recording, which includes more and more the capture of the audience experience. Media Art documentation becomes a resource that facilitates research on the artists and their work for students and academics, who, it is hoped – now in a new Facebook-like communication structure – will contribute to expanding and updating the information. In this way, documentation changes from a one-way archiving of key data to a proactive process of knowledge transfer.

Now, together with an important unknown art collection, the Göttweig print collection, representing 30 thousand prints emphasizing Renaissance and Baroque works and a library of 150,000 volumes going back to the 9th century, like the Sankt Gallen Codex, the Database of Virtual Art strives to achieve the goal of a deeper media art historical cross pollination. Reaching to the present day, the print collection has grown to be the largest private collection of historical graphic art in Austria. Just as the Media Art Histories conference series bridges a gap, the combination of the two and other databases hopes to enable further historic references and impulses. The collection also contains proofs of the history of optical image media, intercultural concepts, caricatures, illustrations of landscapes in panoramic illustrations. For the future, this may provide resources for a broader analysis of media art.

The collection is being made public and researched through four strategies:

- a.) The 'Scientific Facsimile': Our Digitization Center digitizes with up to 72 million pixels. The detailed digitization of this beautiful hand of a colleague seems already a bit impolite.
- b.) The concept of Virtual Exhibitions (now adopted by main museums) addresses, since 2006, the public with online exhibitions like *Venetian Views*. Virtual exhibitions are divided into sub themes and enriched with different picture formats, literature and meta data.
- c.) Cinema Screen sized projections, give new access to details. Digitized prints can be connected in filmic fly-throughs allowing travel through time and space.
- d.) Fortunately, we have the unique situation to have the large media art archive next to a historic art collection: the Collection will be further networked with archives of contemporary media art via keywording.

Of course, you know that keywording can be bridge building too! The hierarchical Thesaurus of the DVA constitutes an approach to systemize the field of Digital Art: out of the Getty Arts & Architecture Thesaurus and the subject catalogue of the Warburg Library in London, keywords were selected which also have relevance in media art. On the other side, out of the most common used terms from media festivals like Ars Electronica, ISEA, Transmediale etc., new keywords were empirically selected. Important innovations such as 'interface' or 'genetic art' have been considered as well as keywords that play a role in traditional arts such as 'body', 'landscape' or 'illusion' and thus have a bridge-building function. It was important to limit the number to approximately three hundred and fifty words so that members of the database can assign, use, and keyword their works without great study of a too complex index. The categories led to natural overlapping, so that the hybrid artworks can be captured through clustering. Important for us was the thematical usability for the humanities: we wanted to avoid something only new, separated from our cultural history.

Let me finish with remarks on the challenging and serious situation of media art research today. With the DVA involved in the field of media art tool development from its beginning, we witnessed the crisis of documentation during the last few years. Since the foundation of the *Database of Virtual Art* (1999 – 2011 and ongoing), a number of online archives have arisen: *Langlois Foundation* in Montreal (1999 - 2008), *Netzspannung* at the Fraunhofer Institute (2001 - 2004), or *MedienKunstNetz* at ZKM (2004 - 2006), the *Boltzmann Institute for Media Art Research* in Linz (2005 - 2009). All these major projects of the field terminated, their funding expired, or they lost key researchers, like V2 in Rotterdam (2001 - ongoing). In this way, the originated scientific archives, which more and more often represent the only remaining contextualized image source of the works, do not only lose their significance for research and preservation, but in the meantime partly disappear from the web. Not only the media art itself, but also its scientific documentation fades, meaning that future generations will not be able to get an idea of the art of our time. Even the Europeana, a large but under-funded project for Europe-wide networks of digital collection documentation is rendered meaningless if the foundation, the archives themselves, are not continued. To put it another way: till now no sustainable strategy exists. If we take a look on media art research over the last 15 years then it is clear: what we need is a concentration of high quality scholarly documentation as well as a huge expansion of strength and initiative. 1.) In the field of documentation – systematic preservation campaigns do not exist so far – it is essential to unite the most important lessons learned and strategies developed by initiatives either existing or abandoned under the single roof of an international institution, that can guarantee persistent existence, such as the Library of Congress or an equivalent European or Asian institution. It would need to be supported with adequate expertise from the network of important archives and initiatives – this could be the best way to protect documentations from being lost. 2.) But also the establishment of an appropriate research institution bringing together the best heads of the field would be necessary. 3.) The European Commission expressed the goal to double funds for pilot projects in interdisciplinary fundamental research! But this is not enough: for up to date digital humanities, the funding structures must be internationalized in ways similar to those enabling modern astronomy, genomics and climatology. In order to create enough momentum and the necessary sustainability, responsible sponsors like NSF, DFG, the EU, etc. have to ensure international long-term sustainable structures. Only when we develop systematic and concentrated strategies of collecting, preservation and research we will be able to fulfill the task which digital culture demands in the 21st Century. In astronomy, the funding agencies developed and modernized their systems towards sustainability. The virtual observatory infrastructure is funded on an on-going basis and there is international co-ordination between a dozen or so countries that produce astronomical data.

For Media Art Research, a commitment by the best experts from the field is needed in a long-term occupation. Let's recall the enormous and sustaining infrastructure that was developed for traditional artistic media, painting, sculpture, architecture, even film, photography and their corresponding archives over the course of the last century. What is needed is an appropriate structure to preserve at least the usual one to six per cent of present media art production, the best works. If we compare the world-wide available budget for traditional art forms with the one for digital culture then we understand how inadequate the support for our present digital culture, the most complex material based art, is; it is almost statistically immeasurable. The faster this essential modification to our cultural heritage record can be carried out, the smaller the gap in the cultural memory; shedding light on the dark years, which started about 1960 and lasts till now.

Hearing that there are experts of contemporary (old media art, sculpture, painting etc) that try to exclude the art of our time with the widest need is sad and ironically, as we learned from Shanken, Cubitt and Thomas, the exponents of an exclusion of media art justify this by its connection with technology.

This confession truly is a disaster, not so much for the interests of those people, but for the tax paying public, who deserves the right to be enabled to think about our time through media art. It might be 'blindness,' but it seems more a desire to keep life easy and save the time needed to understand the immense complexity of media art and its preservation needs. This ignorance is not something we should just tolerate: it means that although our societies – the political, financial, and cultural – are more and more driven by modern technologies, the art market, a number of biennales and most 'contemporary art museums' deny the public, which pays their bills, the needed aesthetic and intellectual confrontation with the art of our time. The attempt to separate art from its time is not new, it is also comparable with earlier movements of world escapism, like the forms of 19th century historicism; but our modern societies need to be enabled to reflect on their time and future and, as we know, media art plays a seminal role in that process.

As we see, Media Art needs as many bridges as possible: conferences, new scientific tools like databases and text repositories, new strategies for documentation and visual analysis of complex data, new curricula for the next generation of teachers and collectors. Maybe in a near future we can create collective tools, as represented in Christa Sommerer and Laurent Mignonneau's work *The Living Web*, which generates a spatial information sphere from search engines for web images in a CAVE. The work represents a new instrument for visual analysis, with the option of comparing up to one thousand images in a scientific discussion. Captivating new visualization tools could provide access to the breadth of digital cultural production, which, coupled with the depth of historical optical media, can enable new unpredictable understandings of today's image revolution.

REDISCOVERING HIROSHI KAWANO – JAPAN’S PIONEER OF COMPUTER ART

Simone Gristwood

The paper that follows stems from interviews and conversations held with Hiroshi Kawano in Japan in 2009 and Germany in 2010, as well as from research undertaken with the support of ZKM|Zentrum für Kunst und Medientechnologie, where the Kawano archive has been held since 2010. The author has also used information gathered through personal correspondence with the artist. This paper forms part of the early stages of an ongoing study into Kawano’s life and work.

It is well known that the 1960s was a pioneering decade in the history of computer art, particularly in the West. However, little attention has so far been paid to equally important work being undertaken in Japan. This paper aims to introduce some of the innovative work that was taking place in Japan at this time, and its origins and activities. With the aim of highlighting the importance of this little known history, particular attention will be paid to the work of Hiroshi Kawano (1925 -). Kawano is a philosopher and aesthetician who was interested in both visual art and music, with the first publication of his visual art as early as 1964 in the *IBM Review*, making him one of the earliest pioneers experimenting with computing technologies in art. The paper will discuss how he first became interested in using computers as a way to apply his theory inspired by Max Bense and Claude Shannon, to visual art. His early theories, influences and experiments in the 1960s will be considered as well as his participation in the First Computer Art Contest Exhibition in Tokyo in 1968 and his first solo exhibition that took place in Tokyo in 1970.

Kawano takes a unique position as a philosopher and aesthetician who approached computing technologies with a view to experimenting with aesthetic theory rather than as an artist or engineer. He first studied traditional approaches to aesthetics in the department of philosophy at the University of Tokyo as both an undergraduate (1948-1951) and graduate student (1951-1955). However, despite his love of traditional aesthetics, Kawano moved away from this approach when he was an assistant in the department of aesthetics at the University of Tokyo.

It was here that Kawano came across the work of German philosopher Max Bense and American mathematician Claude Shannon around 1956. Kawano hoped to find a breakthrough – a new approach to study aesthetics - and after reading Bense (*Aesthetica*, 1954) followed by Shannon (*A Mathematical Theory of Communication* 1948), Kawano saw the potential to use these approaches to aesthetics and the possibility of their application to art. Kawano first published an article about his ideas on Information Aesthetics in 1962 entitled 美学的情報理論の一考察 (*Inquiry into Aesthetic Information Theory*) [1] and soon after began writing about the possibility for using computers for art. In 1964 Kawano began to program computer graphics.

In order to be able to apply these theories, Kawano began to study the Markov process model. Markov chains are probability-based mathematical states demonstrated by sequences of random patterns. The properties of these chains are defined either by their relationship between the present state and that which immediately precedes it, rather than its entire output history, or the present state alone. This approach worked well with Shannon’s theory with regards to language and the letter-based approach if

the alphabet is thought of as a kind of chain. Kawano found that Markov theory had been applied to linguistics and musical expression already, yet he wanted to break from the one-dimensional structure in order to apply the Markov model to visual expression.

Despite studying mathematical approaches such as that of Markov, and grappling with alternative approaches to aesthetics relation to information processing, it was not until a few years later that Kawano began to use computers. Around 1960 the University of Tokyo opened a computer centre that all students, staff and members of the University were permitted to access, and where they could study programming. Kawano began to study programming independently in 1963 in this Computer Centre. He learned the assembler language and used the OKITAC computer. (Fortran, which Kawano first used in 1966, was not introduced in Japan until a few years later). The OKITAC was a room-sized computer made by the Oki Electric Company in Japan that used a magnetic core memory and was attached to a line printer – an output device that influenced, and proved useful for Kawano’s approach.

Kawano first published some of his designs made using the OKITAC 5090A in an article about *Computing and Design* in the Japan IMB Review in 1964 [2] and another (*Series of Pattern; Flow*) in November of that year in the Science Yomiuri. [3] Nevertheless, *Series of Pattern: Flow* was actually only “a prototype for his masterpiece *Simulated Colour Mosaic* using a more complex quadruple Markov chain for the vertical and horizontal directions, which was published later in 1969. [4]

Kawano not only saw the potential for creating visual art using the Markov method, but also other art forms such as poems for which he looked to traditional Japanese Tanka poems of 31 letters/characters. Kawano remembers that programming would take many hours, however, the most time consuming aspect to producing works in this way was making the concept for the tree-type Markov model structure. He recalls the concept might have taken as long as one or two months, but writing the program was simple, and generating the poems was even simpler.

In 1967 Japan held its first (and only) computer art contest at the Sankei Building in Tokyo (though there were further exhibitions of computer art in Japan). The exhibition that was held in March 1968 included exhibited works by the CTG, Kawano as well as the first computer animation in Japan. A summary of the exhibition was published a month later in COMPUTOPIA magazine. [5]

Three years later, in 1970 Kawano held his first solo exhibition at the Plaza DIC, Tokyo for ten days between 5th and 14th October. The Plaza DIC is the exhibition hall of the Great Japan Ink Company, a printing company situated in the Nihonbashi area of Tokyo. The exhibition space was found with the help of Kawano’s friend and well-known graphic designer of the time, Mitsuo Katsui. The preparation for the exhibition took approximately six months. This included time to complete the programming, printing the output and painting the output. The works were completed on a HITAC 5020 digital computer, designed by Hitachi, using FORTRAN 4 code. In an article about the exhibition published in Kawano is attributed to “planning, Programming and text”, the HITAC5020 for “design and works.” [6]

The exhibition is significant because not only because it showcased Kawano’s work - and in particular, *Simulated Colour Mosaic*, as well as other studies and output, but it also showed his early ideas beginning to develop in relation to artificial intelligence and art, a topic he would come to explore more deeply from the mid 1970’s onwards.

This paper has briefly outlined the early stages and work of one of the pioneers of early computer art; Hiroshi Kawano. It has given an introductory overview of the early period in his academic life from when he began to explore new theories and move away from traditional aesthetics in the late 1950s. It has also shown how he progressed to using computing technology to apply his aesthetic ideas to art at a time when internationally, only a few pioneers had begun to explore these areas.

METAPLASTICITY & INNER BODY SCHEMAS: VR FOR CHRONIC PAIN

DIANE GROMALA

This paper describes a new paradigm of VR created for chronic pain that turns ideas of pain distraction inside-out. This paradigm enables manipulation of inner states, emphasizing the role of aesthetics in therapeutic contexts. We propose that this paradigm extends ideas of body image and schema and dissociative states, providing evidence that managing inner states is possible, a process referred to as meta-neuroplasticity.

The three VEs developed to address chronic pain integrate immersive VR with biofeedback, which serves as a primary means of navigation. The VEs are designed to help immersants become aware of and to gain agency with their inner states in an effort to remap their pain and body schema. Copyright Diane Gromala, 2010.

Pain[s]

Pain is a boundary condition – a non-normative experience that can alter one’s perception, distorting it beyond all imaginings. By understanding boundary conditions in more depth, the Transforming Pain Research Group (TPRG) believes that more normative states may be more fully understood.

All humans experience pain[1], an essential warning system that alerts us to injury or disease. Like the historical figure of the pharmakon, pain is indeterminate, unquantifiable and beyond language. When intense, pain is beyond sharing, causing one to curl into oneself in a primal way, stripping away, bit by bit, our most basic feature as a social creature: our ability to communicate or connect with other humans. In *The Body in Pain: The Making and Unmaking of the World*, Elaine Scarry explains that pain “. . . unlike any other state of consciousness – has no referential content. It is not of or for anything. It is precisely because it takes no object that it, more than any other phenomenon, resists objectification in language” [2]. Pain bears other paradoxes: certain kinds, such as childbirth pain, work in tandem with other biochemical actions, and are thus dimly remembered; other forms, like chronic pain, prevent the kind of forgetting that habituation usually enables [3].

Chronic pain is a category of pain that significantly differs from acute or short-term pain. Acute pain is a symptom of a disease or injury; once the originating disease or injury is cured, acute pain subsides. In contrast, chronic pain is defined as a disease, an on-going, degenerative state [4] in which the pain response systems remain ‘stuck’ in high gear. Although chronic pain affects, by conservative estimates, one in five people in so-called industrialized countries [5], little is known about its causes or mechanisms. Because chronic pain cannot be cured, the emphasis is on managing this usually lifelong kind of pain.

Background

1991 marked the seventh year I had unremitting, chronic pain. What seemed like a hundred odysseys in search of even temporary ease led, in that year, to two parallel experiences – universes apart, they nevertheless were what neuroscientists term dissociative states. Far from out-of-body travel, they were scramblings of inner and outer sensations, a fluid, otherworldly state that I glimpsed in meditative practices. These practices enabled me to ‘re-map’ my pain, a hard-won ability, to put it in the background of figure/ground experiences that comprise my moment-to-moment, everyday states.

The first of these two experiences was at the Blue Mosque, during a sunny afternoon in Istanbul. The second was in a computer lab in the Banff Centre for the Arts in Canada. In a kind of fate that is too unbelievable to concoct, I was able, to combine and recreate these experiences in an artwork I produced with Yacov Sharir in *Dancing with the Virtual Dervish: Virtual Bodies* [6]. One of the very first VR artworks, this collaborative effort was continually refined over a decade. The virtual world that immersants experienced was a torso, derived from an MRI of my torso that physicians insisted on in some quixotic quest to ‘verify’ that some non-existent biomarker of a disease or injury was the cause of my pain [7]. By recontextualizing this torso as a virtual environment (VE) to inhabit, Sharir and I strove to create virtual worlds to inhabit in unfamiliar ways. The VE comprised continuously decaying and reforming skeletal bones that defined a non-rectilinear space, while smaller organs revealed unexpectedly immense and abstract worlds.

Although we created this work at the height of technological discourses favoring a disembodied view, ours countered it. In our view, the new sensations of ‘flying’ while simultaneously feeling the tug of gravity, or of becoming aware of proprioception, were experiential states that one could not easily brush away into the bin of disembodied experience. This appears to have escaped art critics at that time, perhaps because the notion of transcendent or dissociative states seem to be predicated on an assumption that one is leaving one’s body, not experiencing it in new ways.

Throughout the next two decades, I explored multiple ways in which diverse technologies could provoke non-normative states that brought usually quiescent, inner sensations to the foreground of awareness, from interactive books made of meat [8] and typographic fonts that changed according to one's biofeedback to evolving forms of VR [9]. Although the TPRG investigates other technologies from robotics to social media, VR is currently our main focus, in part because prior and current research makes it clear that VR provokes or opens access to inner sensations in multiple and persistent ways.

Immersive VR

Building on our experience in creating well-known virtual environments designed for artistic [6], cultural heritage [10] and medical applications [9], we examine the affordances of immersive VR through a fundamental human experience – pain. Known strategies for managing chronic pain necessitate that we design systems which bring inner senses to the foreground of awareness, and sometimes are seemingly exteriorized so chronic pain patients may learn how to remap their pain in sustainable ways.

Although virtual reality is admittedly an unfortunate term, artists and others working in videogames and online communities such as Second Life redefine the terms 'virtual' and 'immersive,' eliding the longstanding distinction between screen-based work and immersive VR as defined by its originating disciplines, or they perhaps mix ideas of social presence with immersion [11].

VR differs from 3D videogames and online communities, however, in the complexity and affordances of its integrated technologies, including interactive stereoscopy, spatialized sound, haptic force-feedback and six degrees of freedom, among others. But the most important distinctions are experiential: in VR, attention is far more directed, and the human sensorium – interceptive and exteroceptive – is tightly bound in technological entanglements, or what computer scientists term feedback loops. And although much of the focus is on experiences manifested within the VE, these experiences persist beyond it. The use of immersive VR for training pilots and surgeons illustrates the profound degrees to which our embodied processes are affected in long-term ways that alter perceptual, neurological, sensorial, autonomic and other systems. The brain and nervous system were believed to have been set in adulthood; however, their long-term malleability that results in structural changes is now recognized as meta-neuroplasticity.

Although similar phenomena may be observed in other media forms, immersive VR maintains specific affordances that are important to explore. The intensity of sensorial and embodied perceptual involvement in VR remains profoundly and measurably different. For these reasons, I maintain the longstanding distinction between immersive VR and other interactive, 3D work.

Pain and VR

The tendencies to create enhanced, unfamiliar and dissociative experiences, and to explore boundary conditions, have deep roots in human history: we have carved out spaces, places and environments; created communal experiences and practices; and ingested opioids, hallucinogens and now-common mood-altering drugs [12]. It is, therefore, perhaps no surprise that humans have developed technologies that function similarly.

Over the past decade, immersive VR has been explored as a non-pharmacological analgesic [13], a sensorially-rich method of 'pain distraction' for attenuating acute pain. This directing of attention outward

proved to be more effective than videogames in reducing pain, and provocatively, is on par with opioids. Simultaneously, V.S. Ramachandran's research in how chronic pain may relate to body image and body schema grew from his use of mirrors to produce analgesic effects for phantom pain [14]. The profound effectiveness of mirrors in alleviating phantom pain led to the acceptance of mirrors as the first instance of 'VR' for pain [15].

Still other forms of technology initiated by Paul Bach-y-Rita enable sensory substitution [16]; this further demonstrated that our neurological systems are plastic or not as hard-wired as was once believed.

Current Work

Currently, our three works-in-progress are varied VEs created to address chronic pain. The first, nearing completion, is the Virtual Meditative Walk, an extension of our prior work, the Meditation Chamber [9]. It integrates VR with biofeedback and a treadmill to train immersants in mindfulness meditation. Both biofeedback and mindfulness meditation have proved to be effective in treating chronic pain [17] through 'self-modulation.' In studying the different forms of meditation across cultures, we chose walking meditation [18] because many who have chronic pain become less active, a phenomenon referred to as kinesiophobia. In the Virtual Meditative Walk, immersants slowly walk on a treadmill while their GSR (galvanic skin response) and HRV (heart rate variability) data are fed into a computer. This data drives the visual, binaural and spatialized sonic elements in real-time. Immersants see a 3D forest that changes form in response to moment-to-moment changes in their physiological data. Immersants also initially hear a vocal 'coach' that guides them through the method of walking meditation.

We are concurrently developing two other prototypes that use similar biofeedback as a method of interaction. Cool! is a snowy world, created in partnership with Firsthand. Seated immersants develop skill in meditating – the more they approach a meditative state, the higher they 'hover,' to about a meter above the terrain. The VE becomes progressively non-realistic, designed to enhance a sense of weightless 'floating' that is often noted by experienced meditators.

Both prototypes comprise several phases. The first phase is designed so that immersants may discover the cause-and-effect relationships between biofeedback and those aspects of the VE that respond. An important issue that remains unexplored by others is that when those who have chronic pain try to meditate for the first time, their awareness of their pain tends to temporarily spike. To address this, we designed non-normative experiences, such as hovering or manipulating proprioception. Proprioception, the sense of where we are in our bodies and where its boundaries may be, affects one's body schema. We think that the unfamiliar experience of distorting proprioception may help immersants manage their initial spike in pain, and may help them discover that they can learn to self-modulate their pain by remapping their body schema. Initial tests appear to confirm that this approach indeed works [9]. The aesthetics of the VE are crucial here, for artists are arguably expert in creating otherworldly or non-normative experiences that are compelling enough to evoke one's sense of proprioception.

Through this work, we have found that visuals tend to pull one's attention outward, while non-linguistic sound seems to remain in an ambient or background relation to attention. Thus, the second phase promotes a transition of focus from the visual to the sonic. It is in this phase that immersants accrue their greatest skills in meditation practices.

The Sonic Cradle, our third and fully developed VE, is predominantly sonic, and does not incorporate any visuals. Immersants sit in a suspended, semi-reclined hammock. They are told little except that they should breathe slowly and regularly from the belly, which alters sounds in real time. When they hear a sound they like, they hold a deep breath in order to 'add' that sound to the on-going sonic composition. Immersants don't know that this VE is built upon Kundalini Yoga practice and theory. The sounds spatially rotate counter-clockwise among four speakers, while a sub-woofer vibrates the pelvis. According to principles of Kundalini Yoga, rotating sound in this way enhances our body's electric field. This system is designed for immersants to add sounds and repetition in order to drive this field up and out toward the ceiling. While little scientific evidence has verified this phenomenon, initial participants report that they feel deeply relaxed and 'float' upwards, which they describe as mildly euphoric. These reactions are probably not responses to any known intention of the system design, since no references to mediation or yoga are made.

Neuroplasticity: Persistent & Intentional Change

In the wider, related arenas of VR research, the process and role of gaining skills to intentionally manipulate inner or interoceptive senses – besides exposure therapy – has rarely been explored. Although 100,000 times more of our resources are dedicated to sensing inner states, compared to those for the five exteroceptive senses [19], our inner states are necessarily quiescent, lest they overwhelm our awareness [20]. Yet humans have the ability to learn how to access and consciously affect some of these inner states, as evinced by yogic traditions, biofeedback and newer technologies with intensive practice, these skills result in longterm changes.

Unlike pain distraction, which is useful for acute pain, the TPRG developed a different paradigm designed to enable those with chronic pain to learn both biofeedback and mindfulness meditation. Both are skills that persist beyond VR, and are standard in managing chronic pain. Obviously, technology is unnecessary for learning how to meditate. However, it provides real-time feedback, which our subjects report is important for learning, and reduces frustration in not knowing if they are making progress [9]. The tight feedback loops and multiple perceptual and sensory modes engaged by VR appear to enhance skill acquisition, according to over 400 immersants [ibid]. Finally, skills acquired in a VE are known to persist. With practice, we believe it is possible for immersants to make long-term meta-neuroplastic changes that may dampen pain levels. Therefore, we are using standard pain research methods to measure pain thresholds.

Our design of these VR systems takes the knowledge of media producers, interactive artists and sound designers as fundamental. Through extensive preparatory interviews and participation by patients, we have learned that in the first phase the VEs must act in direct response to immersant's changing inner states. In other phases, however, the VE functions better as a counterpoint. The visuals and sounds are emphasized and de-emphasized, according to the ways immersants respond.

We have also learned that expectations based on knowledge of other media do not directly translate in immersive environments. For example, when walking and meditating, a meditator learns not to become

distracted by visuals. They concentrate on what it feels like to step forward, using their peripheral vision as an ambient guide. Thus, while we believed that fog would parallel this experience, we found the inverse to be true. Therefore, we are developing principles derived from interactive art, media studies, perceptual science and neuroscience. None provide working principles in isolation, yet their combination appears to work. At present, we are focusing on ideas from the nascent area of neuroaesthetics, particularly by creating a VE to work with and against body image and schema, and by drawing upon aesthetics from Indian and Middle Eastern samas. It is important to note that the ways in which chronic pain affects experience foregrounds our work. For example, those who have chronic pain are often sensitive to certain kinds of sound, and have issues with moving and anxiety, among other factors.

Finally, while recent technological advances have dramatically reduced the cost of VR, it remains relatively complex and inaccessible. Thus, we are testing our systems in physicians' clinics and hospitals so that chronic pain patients will not need to travel to another site. Further, these systems are being extended to home computers and mobile devices, both to reinforce the VR meditation sessions, and to track progress, compliance and changing pain levels.

User testing includes both qualitative and quantitative methods, drawing upon the varied expertise of each researcher. It is particularly fortunate that the preponderance of wider research in chronic pain is based on a biopsychosocial model. While the group members work together to create the VR systems and methods of testing, each member also examines ideas within their particular domain. This approach prevents any one disciplinary bias from dominating, yet allows for concurrent research in each discipline.

Conclusion

Because VR has been successfully used in therapeutic realms, including treating acute pain, numerous researchers have called for the development of VR to address chronic pain [15]. The TPRG is the only group we are aware of that focuses specifically on VR for chronic pain. The VEs we create are designed to help immersants with chronic pain to learn biofeedback and mindfulness meditation techniques. These are long-term, intensive skills which, when practiced, are effective ways of self-managing chronic pain. We verified that the affordances of VR provide real-time feedback that enhances skill acquisition, and are investigating how the roles of dissociative experiences may help initial spikes in pain, and in learning to remap relations between pain and body schemas. Our paradigm runs counter to methods of pain distraction, since it is unreasonable to spend all wakeful hours in VR. By focusing on learning skills to self-modulate inner states, we believe this paradigm may extend knowledge of VR as it relates to body image, body schema, dissociative states, chronic pain and pain self-management. The focus on the aesthetics of VR distinguishes this work from other therapeutic uses of VR. Finally, if our paradigm proves successful, we believe that what is learned in VR and practiced outside of it may persist in ways that reduce pain levels and may result in structural, meta-neuroplastic changes.

BOTANOADOPT, A PARTICIPATORY INTERDISCIPLINARY ART PROJECT

TORSTEN GROSCH & HAIKE RAUSCH (431ART)

botanoadopt is a participatory interdisciplinary art project among art, science and social commitment. The project defines plants as independent beings and offers them for adoption on the internet. A hatch is available for the anonymous local handover of plants. The humorous contextual displacement makes it possible to question one's own definition of nature, and the adoption process establishes links with the theme of responsibility.

Introduction

Botanoadopt is a participatory interdisciplinary art-project among art, science and social commitment. The project shifts perspectives by humorous recontextualizations.

Botanoadopt presents plants with charming biographies as independent individuals and offers them for adoption on the internet. A plants hatch is available for the anonymous local handover of plants. The adoption contract asks adopters to send botanoadopt photos of their fosterlings. These photos are then published at botanoadopt.org offering insights into the socio-cultural environments of the whereabouts of the plants.

The humorous recontextualizations allow to question one's own definition of nature, and the adoption process insinuates the topic of responsibility. Botanoadopt draws on alternative economic models of exchange and donation.

Thus the issue of environmentally responsible behaviour is investigated via models derived from realms beyond the boundaries of art.

Keyrole of plants, artistic statement and strategy

“Never before has the extinction of species been as massive as today. If this development will continue, it is to be feared that within a shortest period of time flora and fauna will shrink by 60-90%.” [1] At the same time plants from all over the world are merchandised as mere decoration items. Several stores offer them very cheap and as a consequence plants are seen and treated as disposables.

Here, at this massive discrepancy botanoadopt comes into play. In merchandise management systems plants are regarded and used as decoration, as food and as supplier of material resources. Woodlands formerly considered as inviolable and to be protected are more and more subject to economic interests. Botanoadopt subverts this political and economical system by defining plants as individual beings and by taking them out of the circulation of commodities. As a result, the only possibility to obtain a botanoadopt plant is by way of adoption.

Botanoadopt is a participatory art-project with the aim of rethinking our idea of nature as such. Plants are playing a keyrole on our planet. They could live without human beings easily. Conversely, men are not able to survive on planet earth without plants. The artistic statement of botanoadopt is: plants are individuals with their own independent perception.

Plants interact with their surrounding in a very sensitive way. For example, they react extremely sensitively to negative thoughts. The book “The Secret Life of Plants” [2] explores the concept that plants may have sensations, despite their lack of a nervous system and a brain. To prove this the authors, Peter Tompkins and Christopher Bird, describe several scientific experiments and evoke a deeper understanding of plant life.

This undergirds our artistic theses: Every plant is to be seen as an individual being with its own perception, its own name and its individual biography. This biography deals with social, emotional, economic or ecological aspects. With the adoption project we are blurring the line between fact and fiction, in order to broaden the perspective, to leave behind common definitions of nature, to open avenues of thought leading to new and individual concepts of nature.

After having rescued several plants from the trash heap in the year 2006, we clearly became aware, that a basic knowledge about plants is not part of our general education anymore. Withered plants are thrown away even if they were able to live on for years to come. Usually, they just need a short recovery time – a normal and necessary process within the cycle of nature. The daily life of industrial societies is no longer connected with these cycles. We think that this loss of being involved into the cycles of nature and the imperative of our capitalist society to be productive all the time and everywhere while ignoring the current critical environmental situation, is the main cause of the immense social and environmental problems of our planet.

Saving plants and giving them up for adoption with name and biography is our strategy, that people become aware of their own definition of nature and behavior. Even a small house plant which could be bought very cheap and easily is a living being.

baseline shifts and modules of botanoadopt

BOTANIA

In 2006 we founded the plants village "Botania". Its name refers to the free city-state "Christiania," [3] which is part of Copenhagen, the capital of Denmark. "Christiania" was founded in 1971. It is a self-regulated state without police forces. Its peoples' aim is to live in peace with each other and in harmony with nature. This idea is strongly influenced by the hippie movement. Accordingly, in "Botania" plants can recover from their sufferings and bad treatments. "Botania" can as well be seen as a symbol for the utopia of living together in peace.

INTERNETPLATFORM BOTANOADOPT.ORG

Nowadays life is deeply influenced by digital technology. So our aim was to realise our main idea with the aid of Internet technology, not only as a means to advertise the project all over the world, but also as a means to help nature. The Internet platform botanoadopt.org was launched at the beginning of 2009 and is a digital interactive network to organize a different and sustainable future society.

The website offers plants for adoption (Fig. 1). Plants handed in from all over Germany are given a name, a biography and an ID picture. The biographies inform about family background, preferences and the respective relationship patterns of the plant individuals. These biographical profiles play a key role in our project and exemplarily exhibit our artistic approach: the humorous shifting of contexts.

Succulent "Edward Tomlinson," [4] a plant of Argentinean origin, grew up in London and has been training Polo since he was a little child. He founded one of the first botanic Polo teams in Great Britain. This team did its secret nightly training in the Royal Botanic Gardens until unfortunately several window-panes got broken by a club. The incident was never cleared up. Nevertheless the players moved their activities to Richmond Park, became the world's best botanic Polo team and arranged tournaments in the Hyde Park once a year. With a handicap of +7, "Edward" is among the best players of his age and committed himself to achieve the official recognition of plants as professional Polo players. Furthermore, he is interested in Sinology and has a liking for red-white checked ties. Edward found a new home in Huddasfield, UK.

Money tree "Lehman" [5] is a latecomer and the youngest of four brothers. He left his extremely materialistically orientated family very early and tried to become a stand-up comedian. Due to certain language barriers and his appearance the audience regarded him as stopgap. But he kept his life's motto: "Humour is laughing in spite of it all!". Against his wish he was brought into a casino and explored the rules of successful gambling. He internalized them and now he helps everyone close to him to gain material wealth that is based on natural growth. Eventually, a leading employee of a German financial institution at Frankfurt/Main adopted "Lehman".

At the end of 2009 an article about botanoadopt and "Lehman" whose name and biography refers to the Lehman Brothers and the crash of the financial market was published by in the German version of the "Financial Times". This article is an example, how deep botanoadopt is interwoven with contemporary society beyond the strong boundaries of art.

Botanoadopt is an entirely non-commercial project. The "currency" adoptive parents have to pay is responsibility. The adoption is regulated by a contract and the adopting person undertakes to send a photo of his protégé to botanoadopt twice a year. These photos are published on the web, so that every visitor can follow the development not only of the adopted plants, but also of the sociocultural environment that is partially documented in the photographs.

WEBSITE AS ADOPTION PLATFORM AND POOL OF KNOWLEDGE

One can easily apply for adoption by an online form. Available plants can be found by full text research and postal code. A checklist [6] for plant adoption offers an aptitude test to every potential adoptive parent. More than 350 plants have already been adopted; most of them live in Germany and some others all over Europe.

In general, the adoptive parents pick up the plant themselves – residence and first digit of the postal code are published on botanoadopt.org, so that plants in your area can be easily found and selected (Fig. 3). Adoptiv parents collect their fosterling at the plant owners home. In this way people independently from their origin, education, religion or social status meet each other. In rare cases plants will be sent by mail or by organizing a lift. On botanoadopt.org it is also possible to put plants up for adoption, a service that has been used by people from all over Germany.

The website offers a huge and versatile pool of knowledge and tagged articles, as well as online-databases on plants and biodiversity. This collection is constantly updated and can be consulted under "Fakten." Thus, botanoadopt.org can also be used as a knowledge base. In addition to biological facts about plants, many more facts about genetic engineering, farming, scientific research, new European laws or biodiversity can be found. Eventually, links to other non-commercial organisations, networks and projects are provided, that altogether aim at a new view of nature. The virtual platform contains a wide range of topics around our central theme plants life.

The page "Media" is linked to documentaries and reports like for instance a documentary film about Monsanto [7] or a report about "Smart Plants" (both ARTE). A "Forum" can be used for knowledge exchange. The whole project combines online- and offline strategies. It brings together global concerns with local actions as well as digital technologies with plants life. Conversely, locally based actions are always announced and documented on the Internet platform and published by using social networks as facebook and twitter. As we implemented the translation tool of Google on our website, botanoadopt can be visited from all over the world.

PLANTS-HATCH

Independently from the Internet, we also wanted to create a space where everyone can hand in his unwanted plant anonymously and without restrictions, instead of throwing it away. Consequently we invented the "Pflanzenklappe" (plants hatch) in which unwanted plants can be put into similar to the

human baby hatch (Fig. 2). The "Pflanzenklappe" takes place at different locations for only a short period of time of 10 up to 14 days. Its idea is derived from the baby hatch, which is very popular in Germany and Japan too. Baby hatches can be linked to the former parochial custom to care about anonymous babies abandoned from mothers in trouble. Those babies were usually left in wicker baskets at church entrances.

The idea of altruism, which is anchored in every religious system, leads to the ethical code of caring about others, particularly about persons with physical infirmities, disabilities or maladies; this code also includes the requirement to pay respect to old persons. Accordingly, adopting a plant or using the plants hatch is an act that shows respect for plants and their invaluable capability to clean our air, to nourish us, to provide resources and medicine, which helps us to relax, to smell good and to have fun.

In February 2009 the worldwide first plants hatch was officially unveiled in Schöppingen by its mayor. The word "Pflanzenklappe" led to more than 100.000 Google-entries within 10 days. Journalists from all over the world were reporting about the plants hatch. The plants hatch 2009 and 2010 was mounted in different districts of Frankfurt/Main and in September 2010 in the botanical garden of Münster. During a period of 10 days, more than 150 plants were left in the plants hatch.

ON-SITE ACTIVITIES

Furthermore, botanadopt arranges regular on-site activities and performances in different cities, e.g. adoption offices and empathy trainings. Adoption offices were installed so far in Frankfurt, Berlin, Cologne, Schöppingen, Münster, Dortmund and London. In 2011 an adoption office offered its services at the Schirn Kunsthalle Frankfurt. The empathy trainings offer "trainees" the opportunity to test their capacity to be empathetic and – at best – to develop and increase it.

BANNWALD - A FOREST MIGRATION

Another botanadopt activity was the "Bannwald-Migration" at Kelsterbach close to Rhein-Main-Airport in February 2009. With the help of proactive supporters botanadopt saved 34 beech tree seedlings from a "Bannwald", that faced clearing because of preparing works for a new airstrip.

In Germany a "Bannwald" [8] is a forest that is protected by law and has to be maintained in any case. The "Bannwald" near Frankfurt was protected by law since the early 1980s as a result of the protests against the runway "Startbahn West," [9] which was being built in a former forest. In 2009, 25 years later, this "Bannwald" had to disappear in order to clear space for another runway.

2009 the company was really well prepared, the whole building area was surrounded by fences and protected by the police. Therefore, botanadopt decided to intervene tactically and create a catch-22: We successfully managed to pass the police barriers unchecked, gained access to the area and collected a big bag of young beech trees, while nature activists were living in tree houses to save the forest.

Finally, botanadopt succeeded to shift 31 of them to the grounds of a foundation in Schöppingen, where a new forest was created – a site-specific artwork called "Bannwald". The mayor of Schöppingen adopted another three beech tree seedlings.

CONCLUSIONS AND FUTURE

botanoadopt saved more than 350 plants since 2009. Most of them were given away anonymously by using the plants-hatch. These plants live in their new homes in Germany and other European countries. In general plants could be adopted by using our Internetplatform or in locally based adoption-offices, f.e. 2011 in front of Schirn Kunsthalle Frankfurt. In 2012 we plan to install the plants-hatch accompanied by adoption-offices f.e. in Cologne. Furthermore we are developing an interdisciplinary participatory education concept, which will start 2012.

COLONIZATION AND SCIENCE NETWORKS BETWEEN PERIPHERIES AND THE CENTER: THE CASE OF THE NATURALIST FRITZ MÜLLER

YARA GUASQUE

The correspondence and the exchange of specimens between Fritz Müller, 1822-1897, and Charles Darwin, 1809-1882, characterize what Bruno Latour called transformation networks. The naturalist's procedure in his observation of the phenomena in loco in the forest could only be legitimized as science after the screening of the "transformation networks".

The construction of scientific knowledge takes place far away from the periphery where data are collected. The scientist, with a focused view that differs from that of the naturalist immersed in the forest, reduces the phenomenon to an abstract inscription. The peripheries with their ecosystems are the ones that feed the centers, with data collected among a diversity of phenomena, through the "transformation networks". The correspondence and the exchange of specimens between Fritz Müller, 1822-1897, and Charles Darwin, 1809-1882, characterize what Bruno Latour called transformation networks. Fritz Müller, a voluntary emigrant in the Brazilian South region, belonged to the first settlement group of Dr. Blumenau's colony in Vale do Itajaí – Alto do Itajaí. He found in Brazil an almost untouched nature which he visited in his lonely pilgrimages along the coast and also in the plateau, accompanied by the highway engineer Dr. Oderbrecht, in the service of Dr. Blumenau. Without having visited the capital city of Rio de Janeiro and without ever returning to Europe, Fritz Müller lived 45 years between the village of Blumenau and Desterro, in Santa Catarina – from 1852 to 1897, when he died – and there he conducted studies and research on aquatic flora and fauna - according to Zillig, 'on commission,' [1] sent by letter to his foreign correspondents. The botanical material expatriated through letters has not been dimensioned. *Oxalis*, *Cassia*, *Abutilon*, *Gesneria* — *Corytholoma*, *Maxillaria*, *Plumbago*, *Coccocypselum*, *Eschscholtzia*, *Heteranthera reniformis*, *Epidendrum* are the names contained in the letters he exchanged with Darwin. Many specimens collected by Fritz Müller in the Atlantic Forest biome, which portray the diversity in the South of Brazil in the 19th century, are in the English herbarium of Kew Gardens. In Brazilian institutions, only 158 samples have been preserved, 152 at the National Museum and 6 at the Botanical Garden. Without quantifying the ones sent to Charles Darwin in the form of seeds or dried specimens, Teixeira, Santos, Hagen and Fontes [2] cite the 483 specimens that Fritz Müller sent between 1867 and 1869 to Joseph Dalton Hooker, who was, at the time, the director of Kew Gardens, near London.

Fritz Müller graduated in Medicine in Germany and, attracted by a libertarian dream that had spread in Europe about life in the recently founded German colony, he abandons his country to run away from social and religious pressures. During the period between 1852 and 1897, in which he lived in Santa Catarina, he established a link with Charles Darwin and with other foreign researchers: Hermann Müller and Wilhelm Müller, his brothers, Hans Spemann, Max Johann Sigismund Schültze, Ernst Haeckel, Ernst Krause, Oscar Schmidt, Carl Friedrich Wilhelm Claus, Wilhelm Moritz Keferstein, Friedrich Hildebrand, Friedrich Ludwig and Friedrich Leopold August Weismann in Germany; in France, Henri Milne-Edwards; in Italy, Paul Meyer; in the United Kingdom, Raphael Meldola and Joseph Dalton Hooker; in the United States, Alexander Agassiz, Robert McLachlan and Herman August Hagen. But he continued exchanging information with researchers in Brazil: Ernst Ule, Hermann von Ihering and Nicolau Joaquim Moreira.

Peer recognition contributed to Fritz Müller's projection as a scientist. In the period in which he lived in Brazil, Fritz Müller received several titles, among which two Ph.Ds, sixteen years after the University of Berlin, where he had studied Medicine, denied him this title because he had not taken the oath: Ph.D. *honoris causa* in Medicine, conferred in 1868 by the dean of the School of Medicine of Bonn, Max Schultze, during the festivities in celebration of the 50 years of the School; Ph.D. *honoris causa* in Natural Sciences by the University of Tübingen, in its 400th anniversary celebration in 1874 – the year in which he was also invited to be Correspondent Member of the then recently founded Argentinean zoological society, National Sciences Society, of Buenos Ayres; and the title of Honorary Member of the Entomological Society of London, in 1884.

Although Fritz Müller's garden is large, the space reserved in the house for scientific work is little and modest. A critic has said that the size and opulence of the laboratories were many times in inverse proportion to the importance of the works that were conducted in them. I remembered these words whenever I saw the small office of Blumenau, from where so many fertile ideas were launched to the world. The small room has only three square meters. Beside the window there is a simple table covered with the most necessary devices for work, among which there is an old Hartnack microscope. In addition, there are a very simple bookcase, a bed and a lavatory, and next to the only worn out chair there is room only for a second one. There are no collections. I don't believe that in the entire Earth there is a wise man who is more worthy of this name that is satisfied with such a modest device. But all the zoologists and botanists know how many scientific results were achieved with that small device. [3]

In his voluntary exile in the Southern Hemisphere – which made him venture as a settler in the recently founded colony of Dr. Blumenau – he starts a pioneer research. The Brazilian ports, open at that time to European scientific expeditions, would not reserve to Fritz Müller, a European among us, the post of sole observer of the flora. The fact of having lived in the colony restricted the interchange of ideas with scientists from more advanced cities of the Brazilian Empire, like Rio de Janeiro and São Paulo, but he conducted an investigation in the open air about the coastal vegetable cover and the crustacean larvae of Santa Catarina. His notes survived the timid environment of Desterro, as Florianópolis was then called, and Blumenau, and were also launched beyond the national network of researchers that was being formed around the National Museum of Rio de Janeiro or São Paulo's Museum. His friendship with European scientists, Ernst Krause, Charles Darwin and Ernst Haeckel, among others, enabled him to publish short papers in *Kosmos*, in *Notícias Entomológicas*, and in other zoology journals, such as *Relações da Sociedade Botânica Alemã*. During his exile in Brazil he produced 237 of the 248 papers he wrote in his life. Many of them, extracted from the manuscripts contextualized with detailed illustrations he had shared with his European correspondents, were published abroad as if they had been written by the addressees of his letters. The publications of the National Museum in the Brazilian territory that had been promised by its director, Ladislau de Souza Mello e Netto, if carried out in time, would not be important to the European scientific circle – despite the effort of institutional consolidation.

Although he worked in Brazil with modest equipment, his enormous advantage was the scientific background he obtained through the education and formal schooling he received in his native country, Germany. Afterwards, in Brazil, his education was consolidated by the network of international collaborators and the activities of teacher and Traveling Naturalist. Immersion in the forest did not prevent him from extracting singular discoveries from the live material he observed. We highlight just a few of them, like the insect-plant interaction in the bromelias and orchids; his ontogenetic recapitulation of phylogeny – recognized as an Ernst Haeckel's proposition; his representation, in branch diagrams, of shared characters to show phylogenetic relationships between species – known today as cladistics; and Müller-

ian Mimicry, about which he wrote in 1875. Developing the Batesian Mimesis, in which palatable butterflies imitate unpalatable butterflies, Fritz Müller demonstrated mathematically that, between two species of unpalatable butterflies that imitate each other, the rarest would have a smaller number of losses, being benefited regarding the non-predation of its individuals in an inverse proportion to the square of the number of its individuals. [4]

His investigation for the National Museum, and his job as an elementary school teacher in the cities of Florianópolis and Blumenau, mix with his difficulties to adapt to the Southern hemisphere and live as a colonist in Blumenau. Beside the hard work in the colony and the distance from Rio de Janeiro, another obstacle that the naturalist had to overcome to act professionally as a teacher, and afterwards as a Traveling Naturalist, writing reports, was the Portuguese language.

The legitimation and the scientific nature of his job depended on the international collaboration network, but also, on the enculturation and formation of the Brazilian research institutions, responsible for the scientific circles that were created around them: the National Museum, the Botanical Garden of Rio de Janeiro and São Paulo's Museum, directed by his colleague Ihering from Rio Grande do Sul, also a researcher in the service of the National Museum, like Fritz Müller. The efforts of Imperial Brazil in relation to equipping the scientific and cultural institutions are determinant, although they were still below the expectation of a European with university education. D. Pedro II was recognized in Europe as a friend of the arts and sciences. It is worthy of note the influence of D. Pedro II on the nomination of Fritz Müller for the post of Traveling Naturalist on October 2, 1876, and on his readmission in 1888 – after having been exonerated due to intrigue in 1884. This influence was highlighted in the necrological text written by Ernst Haeckel, when Fritz Müller died. After the proclamation of the Republic in 1889, the National Museum received information from the Minister of Instruction, Post Offices and Telegraphs of the new Government, determining that the Traveling Naturalists had obligatorily to live in the Federal Capital City, Rio de Janeiro. As he did not want to abandon his family and his home in Santa Catarina, Fritz Müller quits the job definitively in 1891. His residence in Blumenau, where he stayed after being dismissed from the job of teacher of the Lycée in Desterro, was his live laboratory, “where he collected a considerable volume of scientific data that have already been incorporated into the collection of zoologists and botanists all over the world”. [5]

The Europeans believed that Fritz Müller's dismissal in 1884 from the post of Traveling Naturalist had a political connotation. A sympathizer with the monarchy regime and with the influence of the imperial family on the political directions of the country, Fritz Müller - a follower of *Deushtum* among many others in the colony – had become inconvenient concerning the purposes of the new State, and of the creation of the nation in the passage from Imperial Brazil, which had brought the division between republicans and federalists.

To take on the post of teacher in a public institution at Desterro, he became naturalized as a Brazilian. As a teacher of the Provincial Lycée of Santa Catarina, he taught Mathematics between 1857 and 1864 and thought about teaching chemistry and physics, among other disciplines, to the more advanced students. This activity kept him “in uninterrupted contact with all branches of the natural sciences and literature, and this contact was much closer than the one he would be able to keep in the subsequent years of his life.” [5] In parallel with teaching, he researched, in his free time in the shore of Desterro, which is now Florianópolis, the medusas, the Bryozoa, the polyps, and the crustaceans, which resulted in the only book he published, *Für Darwin*. The book, concluded in 1863, was published in 1864 by Engelman in Leipzig, Germany, just five years after the publication of *The Origin of Species*, by Charles Darwin. Since

1861, the year in which he received a copy of this book, his investigative effort derived from his argumentation in favor of the theory of evolution.

Still as a teacher in Desterro, he projects, in one part of the farm where the *Lycée* was built, the creation of a small Botanical Garden. He collaborates with seeds and specimens for this small Botanical Garden and for the National Museum, with replicas that ended up being transplanted to the Botanical Garden of Rio de Janeiro. After the school's renewal, Fritz Müller was prevented from exercising his role of teacher without, however, losing the employment bond. Thus, he could propose to the government the creation of an experimental field on the margins of Itajaí river for planting and cultivating exotic species of the flora that were useful to the country, an activity to which he was designated in 1867. [6] Later on, his collections, scientifically argued and illustrated in detail, enriched the National Museum of Rio de Janeiro. The invitation to the post of Traveling Naturalist of the National Museum of Rio de Janeiro, which Fritz Müller held from 1876 to 1891, was made by Ladislau de Souza Mello e Netto, who was then the director of this Museum.

To contextualize the stage of the equipping process of the cultural and scientific institutions in Brazil, in the passage from colony to Empire, between 1807 – when D. João VI, at the time prince regent of Portugal, abandoned Portugal upon Napoleon's troops' invasion of the Iberian Peninsula, and came to live in Brazil – and 1815, the National Museum was instituted, as well as the National Library, the Fine Arts Academy, the Royal Press, the Bank of Brazil. Three generations of monarchs were necessary so that the Botanical Garden of Rio de Janeiro, also constituted by D. João VI in 1808, could form in 1890 its herbarium, with the donation of a rich collection of dehydrated plants that belonged to D. Pedro II. [7] The herbarium of the National Museum had preceded it – founded in 1831 by the botanist Ludwig Riedel, who participated in the scientific expedition of von Langsdorff from 1825 to 1829 in the country. The job that Fritz Müller had in the Museum between 1876 and 1891 coincides with the advancements of the institutions created in the consolidating Empire and the passage to a new administration of the already republican Brazil.

The conflicting view of nature in the colonization of the South of Brazil can be exemplified by Hoehne's testimony. In the volume dedicated to the coast of Southern Brazil, Frederico Carlos Hoehne [8] highlights the opposition between two words, fields and woods. As the director of the Botanical Institute of São Paulo, which he had founded, a post he held between 1942 and 1952, Hoehne planned to pay homage to Fritz Müller in a singular way, not with a statue to be erected in the urban space, but attributing his name to one of the rough-hewn trails in the lands of the Botanical Institute that still need to be demarcated at the time. He believed this would be a fairer homage than dedicating to him the name of a street or urban square, "in which the completely banished nature cannot establish anymore the relation between the person who has been honored and the reason for the homage." [8] The trails should be "a practical school of botany," [8] immersing the observer and exempting the help of the master.

To Hoehne, the two illustrious figures of the history of colonization of Alto do Vale do Itajaí in Santa Catarina, Dr. Blumenau and Fritz Müller, were opposites. In Dr. Blumenau, Hoehne saw the disciplined obstinacy of a persevering explorer and administrator, an educator, a "man of material initiative." In Fritz Müller, he saw the consolidated scientist who had "the forest as his favorite book", although *The Origin of Species*, by Charles Darwin, was one of the volumes of his extremely reduced library. What determined that his observation became a scientific investigation? What were the implications of having the forest as experimental practice of the observation of phenomena in their complexity? Between the fields and woods, he was thus described: "in the fields, barefoot, wearing a large straw hat, sleeves

rolled up, hoeing weeds from the cornfield, pruning the orange grove, [...] by the Itajaí river or in the woods, collecting insects, observing birds, plucking plants.” [8]

The interdependence between flora and fauna observed in the forest is different from the one observed in the fields and in the garden. Between the forest, the fields and the garden there are different degrees of nature domination, which reduce the complexity of the relations and show the advance of colonization. Knowledge extracted from these collection places, which were Fritz Müller’s laboratory, would have to differ from knowledge produced in the academies’ laboratories.

The garden was the live inventory of his correspondence exchange with European scientists. The proximity to Fritz Müller’s house enabled the monitoring, at different times and seasons of the year, of the rotation of the stems of climbing plants or of the movement of leaves in the rain, and a more comfortable and speedy transposition of these data to his worktable – where he registered them with indexes and formats that were more reliable to science, and in long-lasting media. The fields, even with the utilization of cultivation methodologies, were, at first, the colonists’ subsistence area, with no greater economic ambitions.

The fields, with the felling of the forest and a clearing open in the woods, served the increasing needs of safety and communication of the inhabitants of the colony, which was becoming a city. It was part of the administrative project of domination and rationalization, which saw the native vegetation as a productive force.

In 2010, the REFLORA notice was opened for cataloguing and repatriating the Brazilian native species of the 18th, 19th and 20th centuries that are in two international herbariums. This initiative has strengthened and stimulated the creation of networks of researchers working with the inventory of the remaining flora specimens in the state of Santa Catarina. One of the aims of *Inventário Florístico Florestal de Remanescentes Florestais do Estado de Santa Catarina*, IFFSC – Forest Floristic Inventory of Remaining Forest Species of the State of Santa Catarina, is the update of the list of endangered species. The project expects to conclude, in three years, the mapping of the species that are in the herbarium of Kew Gardens, in England, besides others. Among the species catalogued in this institution, some were collected by Fritz Müller in the 19th century. Of the species planted in Fritz Müller’s garden, fruit of his investigation and correspondence with other foreign scientists, nothing is known. With the discussion about the changes in the Forest Code in Brazil, the trajectory of Fritz Müller’s life and work becomes of paramount importance for reflection. Transformation networks is the movement of the observation carried out in the periphery that is legitimized, as an abstract datum, in the calculation centers that promote an accumulation of knowledge, the surplus value of information. It is in the transformation network that intellectual control is exercised, and through it the centers are capable of representing phenomena that were previously out of their reach. The paper focused on the science network between the German colony in the south of Brazil and the center, with the European scientists and naturalists with whom Fritz Müller exchanged letters, and tried to map the plant specimens that Fritz Müller sent to Europe. The concept is employed in the paper to refer to the naturalist’s procedure in his observation of the phenomena in loco in the forest, and also to highlight that his observations could only be legitimized as science after the screening of the “transformation networks.”

TRAVELOGUE: AUSTRALIAN FORUM PANEL DISCUSSION

MARK GUGLIELMETTI

The focus of my panel discussion centers on Artificial Life, as encoded in three-dimensional computer generated space (3D space), with a specific orientation on the view into the Artificial Life virtual “world”; this view is predominantly mediated through the virtual camera.

Introduction

“A rich history has prepared the way for Artificial Life to make sense” writes Stefan Helmreich, [1 pp.6] reminding us the various dimensions through which to consider the Artificial Life are many. The discursive frameworks that tend to frame Artificial Life include; biology, the genealogy of cybernetics, the history of twentieth century generative art, often economics [2] and, more recently in relation to Islamic Art. [3, 4] It is not without irony then that Artificial Life visualisation *itself* as a specific dimension of the moving image is a somewhat impoverished discursive field with few notable exceptions such as. [5, 6] Reflecting the state of discursive impoverishment is the number of Artificial Life artworks that specifically explore Artificial Life in relation to the grammar of the moving image; *Technosphere* (1995) by Jane Prophet et al and Nemirovsky’s et al’s *Emonic Environment* (2001-2005) are but two exceptions.

How the view into Artificial Life ‘world’ frames our perception of the virtual world is the concern of this presentation. Reframing Helmreich I argue, a rich history has prepared the way for us to *view* Artificial Life images; there are many visual grammars and interpretative regimes that inform our capacity to engage with Artificial Life virtual worlds. In a recent response to an abstract I submitted to a media arts history conference I was surprised to read one reviewer’s response; “The idea of the “virtual camera” in simulated settings is an interesting hold-over from the filmic world and deserves more exploration”. The response was unexpected for a number of reasons, which I address here. Firstly and pro-saically, the virtual camera is simply a de-facto protocol in all types of 3D simulation, filmic or not; it is the tool [7] or device through which to frame the image, window or view into 3D modeling software, VR simulation, FPS games, architectural visualisation, engineering simulation or, the artificial life virtual “world”. Secondly, I argue there is a ubiquitous regime and protocol in Artificial Life image making that draws from *both* science and cinema even if these normative practices are not explicitly obvious to the practitioners creating Artificial Life images. Finally, I argue Artificial Life image making draws heavily upon the interpretative grammars and strategies developed in the scientific nature film. In summary, this paper outlines provisional research that situates Artificial Life visualisation, science and art, in both; the interrelated genealogies of scientific visualisation and cinema and, within a particular discursive orientation traced to Disney animation and nature films.

Science and the ‘long take’

Whilst much research energy has focused on computational techniques to generate lifelike behavior and emergence (Langton) the scopic regime through which to view artificial life “worlds” helps gives rise to the key themes of emergence and “lifelike behavior”; there are interpretive fields through which to *view* Artificial Life worlds. The scopic regime in Artificial Life visualisation is a “hangover” from scientific observation, vis-à-vis devices such as the microscope and telescope, *and* from film/cinema, vis-à-vis Andre Bazin’s device “the long take”; the perception of an uninterrupted view of the world underwrites

both the *arts of reality* [8] and Bazin's long take. Scientific objectivity and the long take function to 'record' an unmediated reality; this reality gives rise to the idea that one looks through a window into a 'world', in this context through a window into an Artificial Life world and not and at an image of Artificial Life (albeit there are exceptions).

The idea behind the virtual camera is embedded in the genealogy of analogue devices such as the microscope and telescope'; the virtual camera impassively enframes the 'world' whilst it simultaneously optimizes the credibility or factuality of the 'world'. Moreover, similar to a photochemical camera (still or motion) the virtual camera 'records' or documents a temporal image of the 'world'; in other words the virtual camera approximates Vertov's "microscope or telescope of time." [9 pp.213]

There are a number of ideas at work here worth considering. Firstly, the camera is employed objectively; as we know objectivity forms a tactical and an interpretive regime.

Secondly, similar to analogue telescopes and microscopes, the virtual camera operates in and is operated on in the 'present tense'; Jenna Ng is instructive here observing that the long take also functions not just to record reality but *presentness*; Ng writes, "Pier Paolo Pasolini attributes presentness specifically to the long take as it is the shot which takes in the greatest amount of reality, and "reality seen and heard as it happens is always in the present tense": "the long take, the schematic and primordial element of cinema, is thus in the present tense. Cinema reproduces the present" [10 pp.133-134] or in the words of the film Director Aleksandr Sukorov's in describing his film *Russian Ark*(2002) "the present continuous." [Sukorov in 10 pp.123] This present continuous has special resonance in Artificial Life image making; with few exceptions the key to Artificial life's *emergence* [11] involves evolving *live* to a "global audience" (Scott Draves <http://electricsheep.org/>).

Thirdly, the virtual camera is routinely considered as a window into a 'world'. Unlike analogue telescopic, microscopic and, photochemical images which are indexical to the physical world, in the case of photography and film they record imprints of light from the world, [10, 12] Artificial Life 'worlds' are not indexical to the physical world, they are isomorphic to a specific computer model. Moreover, the computational models are mathematical expressions that *interpret* the physical world; they are neither indexical nor isomorphic to the physical world. Like all digital images Artificial Life images don't 'represent' the physical world, digital images encode information and "computers produce tokens of *numbers*." [12 pp.131] That "Images are mediations between the world and human beings" [5 pp.9] is a important reminder that an image is not a window into a world it is an image. This point is critical when framed against the very premise of artificial life, which is predicated on "generating *lifelike* behavior [... and] focuses on the problem of creating *behavior generators*." [11 pp.5] Frequently, the success Artificial Life visualisation is dependent on observing or deciphering emergent patterns in the 'world'; what is perceived in the world or on the screen is what there is to perceive. According to Flusser transposing the act of looking at an image into the act of looking at or into a world is "dangerous" business:

What one sees on them [technical images and by extension images created by the virtual camera] therefore does not appear to be symbols that one has to decode but symptoms of the world through which, even indirectly, it is to be perceived. This objective character of technical images leads whoever looks at them to see them not as images but as windows. Observers thus do not believe them as they do their own eyes. Consequently they do not criticize them as images but as ways of looking at the world ... [this] lack of criticism of technical images is potentially dangerous at a time when technical images are in the process of displacing texts – dangerous for the reason that the 'objectivity' of technical images is an illusion. For they are – like all images – not only symbolic but represent even more abstract complexes of

symbols than traditional images. They are metacodes of texts which ... signify texts, not the world out there. [5 pp.15]

The problem with technical images, from art or science, is what you see is *not* what there is, what there are, are highly sophisticated models and concepts that require decoding and the virtual camera is strategically organized to impassively enframe these encoded models.

This account of the virtual camera in Artificial Life has particular resonance with the status of photography and film, from science and art, in the late nineteenth and early twentieth century; “Photographic images, according to the skeptic, were the automatic product of a machine, not of a mind” [13 pp.8] that is, the photographic machine “automatically [reproduced] whatever [found it’s] way in front of the camera lens.” [13 pp.9] The skeptical accounts were later confirmed in the *actualités* or documentary films of the Lumière Brothers [13 pp.9] and exquisitely represented in the photographic work of Karl Blossfeldt, a pioneer of the “New Objectivity” movement in the early 20th century. [14 pp.5-22] As is apparent in the images created by Blossfeldt, the framing of the ‘world’ is a tactical account of ‘reality’, an account that does not automatically record the natural landscape but frames it through various apparatus. Blossfeldt’s formal grammar is often manifest in artificial life image making, for example in Karl Sim’s *Galápagos* (1997) series and in Jon McCormack’s elegant study of the “computational sublime” in *Bloom* (2006) see http://www.csse.monash.edu.au/~jonmc/projects/Bloom/Bloom/bloom_main_page.html.

Disney Animal Animation and the Nature Film

A common feature in Artificial Life research, art and science, is the accompanying publication describing the research. The published material often includes both a description of the target system and a stylized fictional description of the system; the word “world” is such a stylized, rhetorical, descriptor. The beautifully evocative description of the homeostatic simulation *Daisyworld* (1983) suffices as a demonstration; published in the scientific journal *Tellus Series B: Chemical and Physical Meteorology*, the account reads; “Owing to a subtle change of climate, clouds appear on daisyworld. The clouds are light in colour. We will assume that the clouds form only over stands of black daisies because of the rising air generated over these warm spots.” [15] Obviously, stylized descriptions have properties that the models don’t. [16] These stylized accounts of the ‘worlds’ that describe ‘natural’ systems are nature stories, stories that would not appear out of place in David Attenborough’s *Life* series (1979-2010) nor in Disney nature stories.

The fictive re-imaginings of Artificial Life ‘worlds’ have much in common with the nature or wilderness stories popularized by Disney in the 1950s and 1960s and other production units in the 1970s, which re-told stories of a mythic “western interior” as natural ‘progression’ and, anthropomorphized the subject matter. [17 pp.117-120] The similarities between the Disney stories and artificial life narratives, in how they both organize ways of thinking about the world through retelling of ‘eternal’ stories of birth, death, cycle, pattern and adaptation (progression), are many. Compare, for example, the role of the 1950s Disney filmmaker and Artificial Life practitioner; the filmmaker captures or “shoots” something on film and the Artificial Life practitioner captures life in the computational ‘world’ using the virtual camera, both are on the metaphorical hunt for the ‘novel yet familiar’ exotic life form in an ‘undiscovered land’. And similar to the Disney stories that did “something far more than reveal “nature’s mysteries”: [... and] spoke to us of a living and intelligible world beyond the fence of civilization, a world we could enter at will and experience in something like human time” [17 pp.118] Artificial Life proposes a comparable arrangement.

Whilst the reader might find the relationship between the Disney nature film of the 1950s and artificial life unpersuasive consider the 1993 commissioned report by Ars Electronica in which the author of the report, Roy Ascott, details the demarcated exhibition spaces at Ars Electronica. In a provocative gesture “Walt Disney, animal animations” are included as ‘artists’ in the “Artificial Life” section of the Ars Electronica exhibition. [18 pp.296] My reading of this provocation is twofold and interrelated; Disney animations and nature films attempt to simulate the ‘laws of nature’ - Disney animation “follows the laws of physics — unless it is funnier otherwise” observed Disney animator Art Babbitt whilst Disney nature films attempt to simulate life as we know it vis-à-vis the moral and political refractions of life as it is and life as it could be. Disneynature, the division of Walt Disney Motion Pictures Group that specifically releases Disney nature documentaries, renders explicit this interrelation between Disney animation and Disney nature film. Disneynature’s latest blockbuster *African Cats* (2011) is “An epic true story set against the backdrop of one of the wildest places on Earth, “African Cats” captures the real-life love, humor and determination of the majestic kings of the savanna [...] the story features Mara, an endearing lion cub who strives to grow up with her mother's strength, spirit and wisdom [...] Fang, a proud leader of the pride who must defend his family from a rival lion and his sons. Disneynature brings “The Lion King” to life in this True Life Adventure... An awe inspiring adventure blending family bonds with the power and cunning of the wild”. (<http://disney.go.com/disneynature/africancats/#story/>)

Artificial life ‘world building’ is located in this trajectory of nature storytelling; cyberbeasts, virtual organisms and, agents are optimized in a similar vein to Mara, Fang and other ‘big cats’ to fight, breed, and die; moreover we observe them as they carry out the real life drama on the fitness landscape. This relationship between artificial life and the nature film is a theme repeated in artificial life researcher Terzopoulos’s conceptual framing of his artificial life work, for example in his paper *Artificial Life for Computer Graphics* Terzopoulos writes “computer animators can begin to play a role less like that of graphical model puppeteers and more like that of (National Geographic Society) nature cinematographers.” [19]

Artist and writer Michael Punt writes, “the gap between science and entertainment is much smaller than imagined. The interaction and exchange might occur not only in shared technologies but in the very imagination that seems necessary to negotiate our consciousness of the world as complex and ultimately unknowable. Science in narrative cinema and the cinematic in scientific research do seem to function reciprocally to help account for difficult things, providing images, metaphors, and useful descriptions for each other.” [20] Punt’s argument is clearly illustrated in Jon McCormack’s *Turbulence* (1995). Described by the artist as “a menagerie of synthesised forms, evolved within the computer using a process of artificial selection. A video laserdisc contains over 30 minutes of computer generated animation” [21] *Turbulence* is a series of pre-rendered animated sequences that are selected and viewed in no particular order. Whilst McCormack wrote the code to “allow certain algorithms and their graphic progeny to flourish through a recursive process of digital “procreation,” and to terminate others—a case of survival of the aesthetically fittest” [22] the overall experience is expressed through the conventions of cinema as the user/viewer watches the pre-rendered movie files; the camera shots are composed by the artist director and; the narrative arc, regardless of the viewing order, reworks the story of Genesis creation or a “post-Fantasia reprise.” [22] In the words of Michelle Barker “In the end what we see is closer to a narrative cinematic experience complete with sound track.” [23]

Closing Remarks

In Artificial Life image making, a constellation of grammars from science and film are assembled as constituent of a particular 'natural order'. Whilst this 'natural order' appears benign it is important to remember the 'natural order' in Artificial Life is neither neutral nor impartial; the capacities required to engage and interact with the metaphors, models and techniques of artificial life are cultural and political, they are recruited, so to speak, into Hayles' posthuman world [24] in which the machine becomes the model for understanding the human.

At stake in Artificial Life screen based 'worlds' or images is agency both in the terms of the Artificial Life-form and being human; instead of looking *at* animats, virtual pets or "cyberbeasts" perhaps we should consider looking *through* the Artificial Life forms point of view. Virilio's somber observation; "Once we are definitively removed from the realm of direct or indirect observation of synthetic images created by the machine for the machine instrumental virtual images will be for us the equivalent of what a foreigner's mental pictures already represent: an enigma" [25] and Cubitt's astute observation, "Machine perception and human perception are co-dependant and must co-evolve"[26 pp.108] are nice bookends to this topic.

"AI Life" researcher Margaret Boden argues, "An idea can be "possible" or "impossible" only with respect to a specific conceptual space. It is possible if the rules for generating new structures allow for it; impossible if they do not. The more clearly we can map the conceptual space, the better we can identify a given idea as creative, in this way or that." [27 pp.269] If I understand Boden correctly she argues that an idea (as creative) is possible within a specific "interpretive regime", an idea transmitted through a specific dispositif vis-à-vis structures of knowledge, discourse and power. It is through the institutionalised apparatus that I understand Cubitt when he states "Computers will talk to anyone, but only the wealthy teach them to speak, to define what perception might be and what is interesting." [26 pp.47] The irony is this; in a contemporaneous media saturated landscape in which the "new space of mediated vision is post-Cartesian, postperspectival, postcinematic, and posttelevisual," [28 pp.7] artificial life screen based work tends to orient around a single stationary view into the virtual 'world'.

TRAVELOGUE: THE EXPRESSIVE POTENTIAL FOR AN A-LIFE FILMMAKER

MARK GUGLIELMETTI & INDAE HWANG

Travelogue: a recording of minute expressions explores the expressive processes of film and A-Life to propose co-evolving an A-Life world with an artificial filmmaker to evolve a documentary of 'interesting things'. The paper frames the research and examines the potential to expand both the grammar of film and A-Life to evolve a new visual syntax and to create new logics for transitions and alternative visual/thematic analogies.

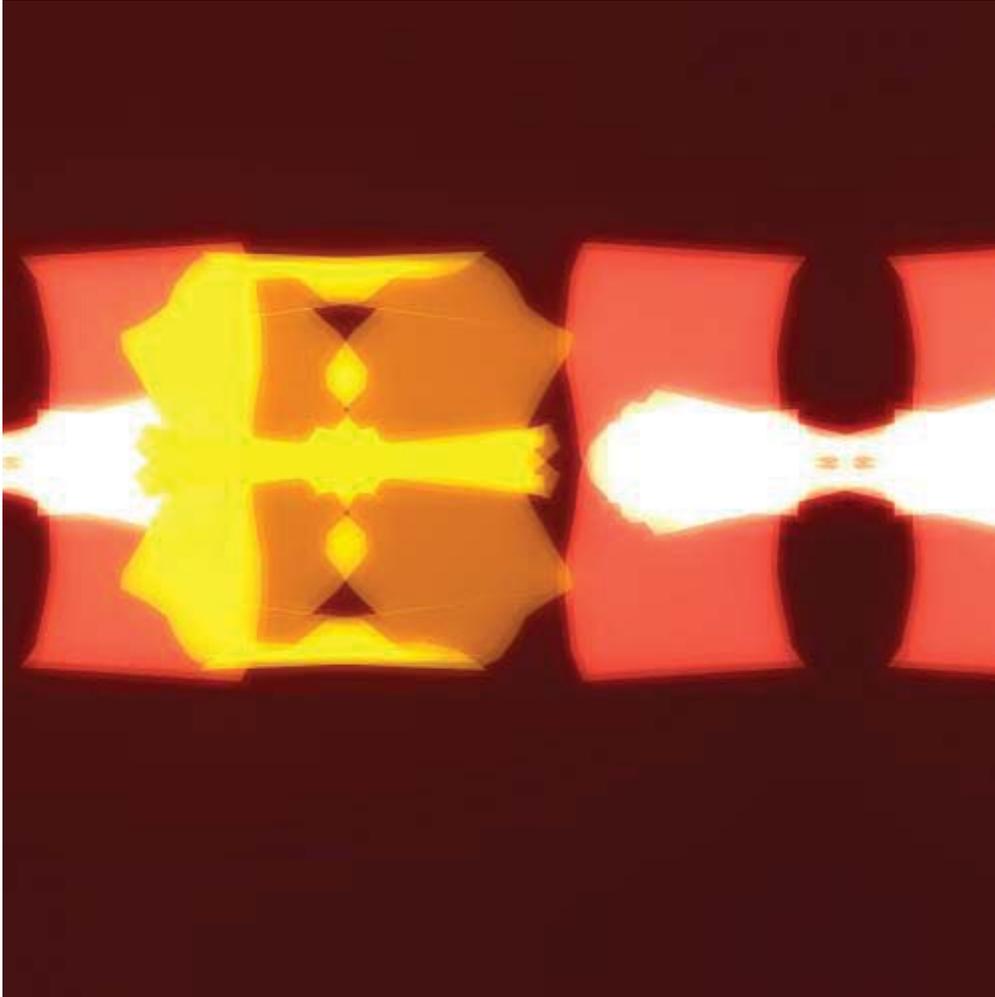

Figure 1-3. *Travelogue: a recording of minute expressions, 2011, Mark Guglielmetti in collaboration with Indae Hwang. Software, code. Copyright the artists.*

INTRODUCTION

The term ‘artificial life’ (A-Life) and Langton’s often-cited trope to locate “*life-as-we-know-it* within the larger picture of *life-as-it-could-be*” are beautifully evocative and provocative, as are the descriptions of the occupants of these “virtual worlds”; such as Sommerer and Mignonneau’s “creatures”, Jane Prophet’s “cyberbeasts”, and Karl Sim’s “virtual organisms.” These creatures, etcetera, often “live,” “fight,” “breed,” “trade” and “die” in the virtual world; that said, rarely do they “work,” “shop,” “cook” or afforded a ‘point of view’; sticky messy descriptions that, apparently, rarely pervade the imaginative and iterative loop of pattern generation. The anthropomorphic machinations of an A-Life “world” are usually described through the discursive framework and nomenclature of science and occasionally economics, more so than from a personal intimate perspective of life.

This institutionalised orientation is not exclusive to the nomenclature of A-Life as a journalistic enterprise for academic publications and as filter for the artist’s press release, but extends to other taxonomies of A-Life such as the interpretive viewing regime of the A-Life world. The normative viewing

protocol through which to view an A-Life world is predominantly through a "window" into the A-Life world; in 3D computational space this window is framed through the virtual camera view into the modeled world. Whilst there are a few notable exceptions, such as *Technosphere* (1995) by Jane Prophet, Gordon Selley et al, I argue there is a ubiquitous approach and standard protocol in A-Life world making that draws from both the practice of science, observation as *raison d'être*, and expressions from cinema, specifically Bazin's 'long take', even if these normative practices are not explicitly obvious to the practitioners modeling these 'worlds'.

Whilst the A-Life artist's vision centers on a range of poetic investigations and interventions, the aforementioned institutionalised discursive orientations and normative grammars are nonetheless political. Observation as a model occupies a long-standing tradition in the west for a social-cultural controlled search for natural order; how we see what we see as a spectator or user is important. [8] A number of A-Life artist's might dismiss this argument, however as Shanken demonstrates in his brief analysis of the *quadri riportati* and *quadratura*, the view into and of the world is critical; varied representational schemas reconfigure our perception and relation to the world. [10] In the case of the virtual camera, observation vis-à-vis the 'long take' stands in reserve as the de facto protocol which functions to record (shoot) an unmediated reality of the A-Life 'world', perhaps for good strategic reason; when "we abandon the notion of a camera as an adversary to the world ... and instead place the accent on its "natural" connection to the world, we reach another, more orthodox version of a camera. This approach stresses the necessary, scientific links among objects, light rays, and film emulsion [...] A camera comes the bearer of tokens from the world." [4] A natural order is established in service of scientific method; measurement, classification, documentation and re-presentation arbitrate fact from magic, facts are not man made, as Shapin and Schaffer observe "it is not I [the experimenter] who say this; it is the machine." [11] The apparatus of the scientific optical device, including telescopes, microscopes, the immobilized lens, in other words the *arts of reality*, [9] stand in reserve to observe and reaffirm a natural order; the virtual camera affords a strategic 'world view'.

During the "speculative pre-history of artificial life" [5] cybernetic artist and theorist Roy Ascott openly contested "deterministic vision" in art, writing; "The perception of our own times is more inclusive and panoptic; the simultaneity of events and their endless changeability have called for a depth of field that zooms from the microscopic to the macroscopic." [2] Whilst contemporary new media artists explore the "microscopic to the macroscopic" in an infinite array or indeterminate number (n) of expressions in software and hardware, including the virtual camera in A-Life's sibling Artificial Intelligence, the virtual camera in A-Life predominantly remains underexplored; the entire parameter space or *phase space* of the virtual camera in A-Life is up for grabs.

PROJECT DESCRIPTION

The project *Travelogue; a recording of minute expressions* is a hybridized visualization-generative-cinematic system exploring the tension between the microscopic and macroscopic, and it does so to examine a range of cultural grammars including; the scopic regimes of both the 'long take' and montage; representation and aniconism; narrative and visualisation; in other words, grammars of realism (without the ideology that underwrites much in A-Life, the biological metaphor). The work is rendered in real-time in three-dimensional software (3D space) and displayed as a multi-channel installation; at ISEA2011 the work is displayed in two 24" LCD monitors.

The central motif of the work draws inspiration from Islamic art including Turkish and Persian carpet making, see Figure 1. The motif strategically orients both the project and A-Life, including ‘emergence’ as *de rigueur and practice*, into the longer genealogy of the human enterprise. Whilst much is made of the critical role of emergence in A-Life, [12] the conception of emergence in art precedes A-Life in Islamic art and carpet making; Laura Marks observes, “both Islamic art and algorithmic media enact the emergence of Everything (or, A Lot) from One (or, Not Much).” [7] For Christopher Alexander emergence in A-Life is even more tightly connected to Islamic carpets in that the purpose of the carpet was more than to create a representation of life as it is but moreover to generate life as it could be in the “emergence of a being” or God; “A carpet is a picture of God.” [1]

The “world” in *Travelogue: a recording of minute expressions* is seeded or initialized with statistical census data on tourism in Turkey, September 2010; data from the “Monthly number of arriving foreigner visitors” provides the initial ‘resources’ to populate the work. Other data, such as “\$ spent per foreigner” and “Number of foreigners of Nationality and Group of age-gender” populate other variables in the system; these variables are used to mathematically describe ‘agents’ (expressions). During runtime the expressions “engage” with other expressions; this “engagement” is not visualized, reducing the capacity to anthropomorphize the system. The algorithmic transactions between expressions provide various resources to other expressions, which enable them to change scale, colour, location, number; similar expressions enacted in other A-Life systems without layering the expressions with slippery terms like “fighting” or “breeding”. The orthographic view into the work frames and gives context to the system; the resulting moving image might be described as a re-imagination of the *potential* enfolded tourist trade in Turkey but just as well be described as an expression of the system.

The second screen displays a view as expressed from the virtual camera in the “world”. The format of the virtual camera expressions draws from a variety of grammars from the moving image, such as montage, zoom, pan etc. but also novel expressions unique to 3D software space such as rewiring the virtual space’s *z-buffer* to reorganise the drawing logic of the virtual space in relation to the virtual camera, as discussed in Guglielmetti. [6] The virtual camera/filmmaker shoots or *nframes* what is ‘interesting’ to it; whatever that interesting is, is unknown to the author. See Figure 2-3.

The virtual camera in *Travelogue; a recording of minute expressions* does not attempt to capture or attempt to construct narrative as it is or narrative as it could be. Moreover, any attempt to reconfigure the project within a user-centered utilitarian approach found in some A-Life art [12] misses the point; this is a process-centered work that self-regulates the microscopic to the macroscopic. The virtual camera expressions resist, to limited degree, the “patterned clichés” enlisted as normative narrative protocols in addition to any claims to “realism.” [3] In other words the virtual camera functions as “an eye unruled by man-made laws of perspective, an eye unprejudiced by compositional logic, an eye which does not respond to the name of everything but which must know each object encountered in life through an adventure of perception.” [3]

CONCLUSION

Travelogue: a recording of minute expressions is an initial and tentative foray into the potential for artificial life filmmaking with much predicated on the “virtual camera” in 3D space. The virtual camera is critical for this iteration of the project in that it simulates a fully functional *digital* camera; the virtual camera is an array of algorithms, some of which are mapped to functions that have equivalence in physical digital video cameras others specifically used for ‘post production’ effects, such as motion blur or glow. In

and around these technical constraints have developed various grammars of the moving image; for the purpose of ‘simulating’ a subjective point of view these grammars persist in *Travelogue*.

However, the virtual camera is host to a range of algorithms, such as the z-buffer, that specifically encode *3D space* and have neither correspondence in the physical world or in other software formats. The challenge for research into the grammar of artificial life filmmaking is to jettison the "camera" itself as the primary metaphor to describe the view into a 3D space; there simply is no camera. Meredith Hoy rightly observes in her ISEA presentation description for *Virtual Resistance: A Genealogy of Digital Abstraction*, “computationally generated pictures analogize and favor the visual qualities of a world seen through a camera lens”. Hoy’s statement has particular resonance in visualizing 3D space in FPS games, VR, machinema, artificial life, architecture and engineering. Any extended investigation into artificial life filmmaking for the purpose of creating a new syntax and visual grammar must include a closer inspection of the infinite array of views into the world for the purpose of re-compositing these views into a non-photorealistic rendering of the ‘world.’

This experiment into an extended range of capacities in A-Life imagemaking is inspired by artist and experimental filmmaker Stan Brakhage who understood what is at stake perhaps better than most:

the increased programming potential of the IBM and other electronic machines [are] now capable of inventing imagery from scratch. Considering then the camera eye as almost obsolete, it can at last be viewed objectively and, perhaps, view-pointed with subjective depth as never before. Its life is truly all before it. The future fabricating machine in performance will invent images as patterned after cliché vision as those of the camera, and its results will suffer a similar claim to “realism.” [3]

THE RHYTHM OF CITY. GEO-LOCATED SOCIAL DATA AS AN ARTISTIC MEDIUM

Varvara Guljajeva & Mar Canet Sola

The paper introduces our approach for applying geo-located social data for artistic purposes, and elaborates on the related artworks. By describing The Rhythm of City we explain an innovative and artistic way for using geo-located data as a score in real-time. At the same time, the data represent a city's pace of life. We stress the malleability of the digital world to the physical one, and the interpretation of social data for artistic purposes.

INTRODUCTION

Starting with the inspiration for the project, Bornstein & Bornstein discovered a positive correlation between the walking speed of pedestrians and the size of the city. [14] Robert Levine [10] demonstrated the faster pace of life in the northern, economically developed and individualistic countries in his study. In short, the investigations proved that it is possible to describe a city and its' culture by the speed of inhabitants and services, and its location.

Consequently, we assume that the digital geo-located social data can give us similar results: in economically developed countries bigger cities generate more digital social content rather than the cities of undeveloped countries. In other words, we believe that the analyses of geo-located social data will give similar results as have achieved Bornstein & Bornstein and Robert Levine. Thus, the aim is to artistically relate to these studies.

Our assumption is based on numerous facts and writings. First of all, the society is going through the digital revolution and we are living in the information age. Social media has gained an important role in our lives. Kristie Fisher and Scott Counts state in their paper that the relevance of social software is already comparable to the older media like books and television. [5]

In addition to that, location-aware ubiquitous and mobile technologies allow us instant participation in digital social networks. For example, Twitter has announced "182% increase in the number of users tweeting from mobile devices in the past year." [9] That brings us to a conclusion that social media are well received and extremely used by the society. The usage of Internet is much more than the source of information nowadays. Social media are extremely engaging by encouraging socialization and expression of own thoughts, moods, and reporting on the events. Thus, it can be claimed that microblogging and upload of various media is becoming an integral part of social life.

Fujisaka, Lee, and Sumiya state in their paper that a significant part of population is sharing its' daily life and social events through microblogs, like Twitter. Even more, the growing usage of mobile devices makes blogging more popular and accessible. It means people are reporting about happenings, their activities, feelings, etc instantly. [8] The authors refer as well to the fact that it is possible to make sense of the microblogs' data. Although the messages on Twitter are short and have limited information, many researchers are looking for a set of mass movement that allows "discovering interesting and useful patterns such as social/natural events or social customs/culture." [8] All this is possible because of a location and a time-stamp that are involved into many posts in social networks. As well Kristie Fisher and Scott Counts see Twitter as "a very large and rapidly changing information source." [4]

Drawing on these facts, a city's culture, events, and pace of life can be observed by analyzing the geo-located social data. Paul Virilio concludes following: "a virtual reality that dominates the reality while disturbing its own idea of 'reality'." [13] Therefore, it is inspiring for us as artists to use the data of social media as a material in our artistic practices. Moreover, it allows us to reflect upon the phenomenon of hybrid virtual-physical world and provoke discussion.

CONCEPT

The Rhythm of City has a multifaceted concept. First of all, geo-located data are translated into the mechanical rhythm of a metronome. The same rhythm represents a city's pace of life. Second, there is a twist from digital to physical. The digital data are translated into physical kinetic motion and mechanical sound. Thus, the meaning of information has been altered and applied for totally different purposes. The same has happened with a metronome – the device has been given totally new and unexpected function from its' original one.

And finally, the users of geo-located social media are influencing the rhythm of a metronome in real time. It constitutes that The Rhythm of City is an installation that can be viewed as an open work, which score is dependent on geo-located social data. As well the work goes under real-time art according to Jeffrey Crouse. [6] He states that this kind of genre of art comprises two distinct parts: the information source(s) and the work it self. The art piece on its own gives a new frame for the data source, and at the same time, alters the meaning of it. Hence, the information does not stand for the information anymore, but for something totally different. In the case of The Rhythm of City the geo-located social information of sources are transformed into a rhythm of a metronome in real time. On the other hand, The Rhythm of City can be seen as mixed reality installation because it crosses and blurs the borders of virtual and physical spaces.

In addition to that, the artwork can be viewed as a representation of a city's pace of life. In other words, the tempo of a metronome is an interface of a city. Through observation one is able to make a conclusion on the tempo of life in certain city and compare different locations between each other. Hence, the installation can be perceived as a performance by 10 metronomes representing different cities but also one is able to observe a single metronome and listen to a specific city (Fig 1).

When it comes to our inspiration for using metronomes, we were greatly influenced by György Ligeti, who composed "Poème Symphonique for 100 metronomes" in 1962. [12]

Ligeti's work is a relevant reference in terms of score composition and applying a mechanical object as a musical instrument. In addition to György Ligeti, many other Neo-Dadaists and Fluxus artists, like John Cage, Eric Andersen and many more, were looking for new forms of score and art in general. Chance played a significant role in their works often. Basically they treated an art piece as a field of possibilities that underlined the role of chance and choice. [2] We see a number of parallels between The Rhythm of City and the early works that used chance and choice as an integral part of the composition. It constitutes that the geo-located social data play a role of chance in the composition. The important difference is that the tempo of metronomes goes beyond chance and adds cultural meaning. Moreover, the work builds a bridge between virtual and physical spaces, and thus, is a manifestation of networked society and digital age. As Lazlo Moholy-Nagy puts "art crystallizes the emotions of an age; art is mirror and voice." [1] Hence, we are making use of modern technology in order to explore a new possibilities and forms in contemporary art, and to reflect upon the networked age.

REALIZATION

In order to achieve the most accurate rhythms of cities, multiple social networks as the sources of social data are used. According to the selected cities the recent geo-located social data from Twitter, Flickr,

and Youtube are retrieved every minute. Thus, for each location the score is composed periodically. It is a combination of recent social activities in the three social networks.

In short, the software robot of The Rhythm of City gets the number of posts from the social platforms in the last minute and converts it into the rhythm of a city proportionally based on the current trend. All this is repeated every minute (Fig 2).

Explaining the dedicated software, the application was developed in Python. The specific programming language was chosen because Python is an optimal solution for creating web crawlers. Web crawlers is a software-based search robot, known as well as web-spider that analyses web according to the target. In this case, web crawlers is looking for the social data appeared in the last minute on selected social services and afterwards counts the new input. The query of search robot is location specific. It means the program is looking for the new social data only in the declared cities.

The database was created in MySQL for storing the information gained from web crawlers. All location specific values that are used for generating the rhythm of each metronome are placed into the database. The database is used as well for storing the historical data of each city in order to understand the local activity within the social media networks. It means the rhythm of every city is compared to its' historical data periodically. Hence, we are normalizing the data of each location in order to ensure accuracy of the rhythm. The quantified data is then returned to Python application that forwards the rhythm value of each metronome to Arduino every minute.

Continuing with physical part of the project, it consists of modified metronomes and a microcontroller. Arduino (microcontroller) is connected to dedicated computer in order to obtain the scores of the metronomes every minute. The score from 0-255 is translated to the different rhythms by ArduinoMega and forwarded to the servomotors.

The metronomes used in the installation are modified: inside each of them is placed a servomotor that is realizing the tempo of metronome sent by the microcontroller (Fig 3).

LIMITATIONS AND REASONS FOR APPLYING CERTAIN SOCIAL NETWORKS

Twitter, Flickr, and Youtube were selected as data sources for several reasons. First of all, these social services are widely used all over the world and have been applied for describing epidemics and other social events in several studies. [8] Therefore, the score that is a proportional combination of users' activity within these social networks is reliable and realistic for representing the rhythms of cities. Moreover, the project is one of the few ones that apply a combination of data sources and evaluate their importance. Normally just one source, for example Twitter, is applied for extracting and translating social data.

The second reason for selected specific social application was available search by a city. For example, Google provides the geo-located search by country only. Opposite to Google Twitter, Youtube, and Flickr support search by city in real time and therefore were applied in the project. However, it is possible to expand the number of used social networks. For example, Wikipedia could be considered as an additional source for the score calculation.

Concerning further limitation, it is important to point out that certain social networks are banned in some countries. For example, Youtube, Twitter, Facebook, Google and some more web sites are totally or partially blocked in China. It constitutes that it will be difficult to include any Chinese city to the installation.

RELATED WORKS

The explosion of web technology and digital culture continue to be an inspiration for many artists. Moreover, virtual social environment is applied as an artistic medium often. For example, Julian Popp has produced amazing artworks based on his significant exploration of digital culture and real-time web as an artistic medium. Bit.Fall is an installation that displays the most popular keywords of current online news. The words, extracted from digital sources, can be read only for some seconds while the water drops are falling. [11] An art piece from 2003 by Jonah Brucker-Cohen called PoliceState, is another example for applying digital data as a concept and a medium that affects physical matter in real-time. The artwork points out the fact that certain governmental organizations, like FBI, are snooping users on Internet. The artist has developed a software script that makes use of the data being “snooped” by the authorities and turns it into the radio signals that control the toy police cars. [3]

Urban Mood by Mahir M. Yavuz is another project that uses geo-located tweets in order to describe the mood of a city. A single word that is a summary of a post is projected for a minute before displaying the next one. [15] The installation remains in the digital environment. However it demonstrates well how geo-located social data can be used for artistic purposes within the virtual space.

The next related example is News Leak by Timothy Devine, Jamey Cochrane, and Shervin Afshar. In the similar way as The Rhythm of City News Leak brings together virtual and real world by extracting local online activities from Twitter, Flickr, and Google News; and publishing the social data as a kind of instant publication in public space. In short, the authors are collecting geo-located data and giving it a form of publication as soon a person press a button of a dedicated box. [7]

To sum up, there are a huge number of arts, who apply social media as a concept and as well as an artistic medium. Interestingly there are much less artists, who make use of geo-located social data. And even less of creative people are concerned about transforming intangible geo-located social data into a physical form. There might be many reasons for that. First of all, technically it is not trivial tasks to analyze location-based social data and transform it into an artistic material. Second, social media platforms have a number of limitations and not all service providers are eager to share the data, like Facebook.

CONCLUSION

To sum up, The Rhythm of City is an inter-disciplinary artwork that demonstrates creative approach towards emerging social web technology. At the same time, the artwork draws attention to the vanishing border between virtual and physical, and allows perceiving a city’s digital pace of life.

In addition to that, the artwork introduces a unique experience to its’ audience. Suddenly it is possible to see and hear the cities’ pace of life that is performed by mechanical metronomes. The score is unpredictable and unique because the digital inhabitants are the composers of the score in real-time.

In conclusion, a significant amount of artworks that exist in hybrid space constitutes the increasing interests towards digital culture, and possibilities of real-time and location-aware web. Hence, the borders of electronic art are widening rapidly.

FROM ASSISTANT TO PERFORMER: THE CHANGING ROLES OF TECHNOLOGIES IN DIGITAL DANCE

ZEYNEP GUNDUZ

The aim of this paper is to demonstrate that the integration of technology in the choreography of staged digital dance changes the role of technology into a performing element onstage and to a dance partner for the human dancer.

The performance takes place in the venue Fabrica in Brighton. The audience looks down from all sides of the theatre upon a square, white floor, which functions as a stage and as a screen. The performance begins with the appearance of three straight, short white lines on the floor. The lines move horizontally from the left to the right of the stage during which they extend in length. To the right of the stage, the three white lines converge to form a diagonal and then disappear. A moment later, a bright, white light illuminates the theater. The dancer appears on the left of the stage. She is sitting in a curled position. Similar to the lines before her, she too walks horizontally from the left to the right of the dance floor while maintaining her curled position. In the meantime, a white line traverses her body vertically and moves with the dancer to the other side of the stage. During this passage, the line moves forward and backward simultaneously with the dancer as she shifts her body weight forward and backward. Gradually, a second light appears onstage. This time the light forms a silhouette around the dancer's body and contracts and expands together with the dancer's movements. In addition, the silhouette intensifies its amount of light as the dancer intensifies the force of her movements, in particular the movements of her arms and legs. The scene ends with the dancer and the light next to each other. Each in their own way, they perform the same movement phrase (organized movement into units of time and space) while moving simultaneously in the same direction. At a certain point, the dancer stands still and watches as the white light grows to cover the entire dance floor, and then, slowly shrinks back down to a spot in the dark before disappearing.

The above paragraph describes the opening scene of *Glow* (2006), a recent example of a dance practice labeled digital dance. *Glow* is made by the choreographer Gideon Obarzanek and the media artist Frieder Weiss. Weiss's website promotes *Glow* as a "spectacular 27-minute duet for body and technology created with the "latest video-based real-time interactive technologies that operate with sophisticated motion-tracking software." [1]

Watching *Glow* left me feeling disoriented. Although simple, there is something peculiar about *Glow*'s choreography as a result of the replacement of one of the human dancers with interactive technology in its presentation of a 'duet'. To start with, the projected images are present on the stage throughout the entire performance. Therefore, the actions executed by the technology, perceived in the form of projected images, are over-exposed for the perception of the spectator. Second, the projected images play an active role throughout the performance in conjunction with the movements of the dancer. In turn, the movements of the dancer seem to complete the movements of the technology and vice versa. Hence, *Glow* seems to portray two different types of movement to be perceived onstage: human and technological. *Glow*'s choreography raises many questions: How can one dance with computer technologies? What is the role of technologies in this performance? And why do I feel so disoriented by watching *Glow*?

The second viewing of *Glow* made me realize that *Glow's* choreography is peculiar because it does not fulfill my expectation of a dance performance, which is—in a strict sense—to see dancing bodies onstage. Technology, however, does not form part of my expectations from a dance performance. Rather, I perceive technology at moments in which technology creates a certain effect on the dancing body: for example, when side-lights add an extra lyrical effect to the movements of the dancer. Hence, there seems to be a certain hierarchy in my perception of a dance performance. In this ordering, the human body is of primary significance while technology seems to be of secondary prominence. Moreover, I realize that until this performance, I have paid little attention to relationships between dancers and technologies.

The integration of technology in *Glow's* choreography, however, seems to unsettle this primary/secondary positioning of the human dancer and technology to which I am used to. The staging of technology in *Glow* requires a distribution of attention between the human dancer and the projected images provided by the technology. In fact, technology seems to occupy a role equal to the dancer's and it seems to function as a central element of the choreography. Although non-human, the central role played by technology leads to the unconventional idea that technologies may function as performers in the choreography, alongside the human dancer, in the sense of executing an act in front of an audience.

Historically, in theater, technologies have most often functioned to assist the performance and to direct the focus of attention to the performer onstage. An extensive description of the historical role of technology in Western European theatrical presentation is offered in the work of Christopher Baugh (2005). A key observation of Baugh's is that the assisting role played by technologies, in particular in the 19th century, has led to a neat division between the animate and inanimate elements onstage. Interestingly, Baugh uses a rather incidental expression to describe this division. The term he uses is "hierarchy of perceptual importance", and although in his text it operates as an incidental term, it seems to neatly conceptualize the clear division of roles he describes. [2] As such, and because of the relevance to the present paper, the term is adopted as a key-working concept in this presentation.

Baugh locates the roots of the hierarchy of perceptual importance in the changes in artistic values and infrastructural developments in theater in the 19th century. For Baugh, the changes that took place in theater in this era are highly significant because they led to a dominant understanding of the functioning of theater, in which the theater text and its mediation via the actor stands central. Technology, on the other hand, functions to assist the actor onstage or to enhance the dramaturgy of the art work. In fact, Baugh explains that the 19th century functioning of theater was so influential that it designates a paradigm in theater, which remained constant until it was challenged in two different eras in the 20th century. The first challenge came with the onset of modernist and avant-garde approaches at the beginning of the 20th century. The next most significant challenge to the paradigm of theater came in the last three decades of the 20th century, with the shift towards the postdramatic paradigm and continues to grow in strength. Nevertheless, despite these challenges Baugh writes that the paradigm of theater and its associated hierarchies are still widely understood in the domain of theatre and performance.

Artistic and infrastructural developments in the 19th century European theatrical dance presentation show many similarities to the developments in the 19th century theatrical presentation. Also in dance, the 19th century designates an important era in which dance as art form went through major artistic reforms in form and content, accompanied by infrastructural changes. Each in its own way, the shifts in the infrastructure and artistic status of dance as an art form in the 19th century can be seen to contribute to the hierarchy of perceptual importance in dance.

For example, whereas in the 18th century, the dancer had to make great effort to maintain the audience's attention, in the 19th century, the changing value of the dance as a serious art form, and the infrastructural changes in theatres, with a separation of the auditorium and the stage, demanded nothing else but the audience's full attention to the action, and thus, the human dancer onstage. Another strategy to keep hold of the audience's attention to the action onstage was to reduce changes in set design to a minimal level. As Alexander Bland explains (1976), at the start of the 19th century, in dance, stage design showed a tendency for simplicity and was not necessarily designed for tricks and surprise effects, which could distract the attention of the audience from the performance. [3]

In addition, in the 19th century, a shift in the status of the female dancer shaped the audience's perception to what they should be seeing onstage, namely, the dancing body. An important shift in the 19th century is the introduction of a star system and the rise of the female dancer. Although Bland points out that the star system could not have taken place if it was not for the invention of gas lighting that allowed the dancers to be individually noticeable by the audience, Selma Jeanne Cohen underlines that in the 19th century, "innovations in theme, in technique, costume" accentuated the artistic and physical qualities of the female dancer and they "all centered on her." [4] Moreover, the rise of the star system, with a particular focus on the ballerina indicates that the position of the human body onstage is even more stabilized and centralized, because the evaluation of the choreography is now to a large extent reliant on the performance of the ballerina, meaning the demonstration of her artistic and physical skills in front of an audience. In sum, the staging of dance in the 19th century implies a separation of the roles of the animate and inanimate elements onstage.

Moreover, the influences of the understanding of technology as assisting devices for the human performer, and thus a hierarchy of perceptual importance, can be detected in current studies on the role of stage elements in dance. According to stage designer Rouben Ter-Arutunian (2004), in most cases, technologies simply support the choreography and the physicality of the dancer as elements of stage design, such as lighting, costumes, and scenery. [5] According to this linear working mode of creation, first the choreography is created whilst the supporting elements, such as lighting or costumes, are designed when the choreography is finished. Hence, technology is not a part of the 'dance proper' but is considered as an additional element to give the choreography a final touch.

The division of roles between the human and non-human elements in dance can also be demonstrated by considering the words of dance scholar Selma Jeanne Cohen. Cohen describes the elements of standard theatrical dance as "a performer equipped with movement skills, a role to be played, a stage to lay on, music, costume, and décor to enhance the spectacle, an audience to respond to it." [6] Here, the performer is introduced as the primary focus and the other elements are introduced to enable or enhance the focus in one way or another, which, in most cases, lead to reduce the relationship between dancer and technology to a minimal level. In sum, the hierarchy of perceptual importance leads to the creation of certain roles and relationships amongst the human dancer and technology in the staging of the choreography.

This paper argues that the integration of technology in staged digital dance, [7] exemplified here with *Glow*, may represent a turning point in the understanding of the role of technology in dance as assistant devices to the human performer. The specific integration of interactive technologies in *Glow* cannot simply be seen as an extension of the conventional role of technologies as assisting devices in dance. Rather, this paper argues that, in *Glow*, technology functions on a higher level, as a performer, alongside the human dancer, which leads to certain shifts amongst the roles and relations in the involved parties within the cultural practice of dance. Due to restrictions, in this paper, I will focus only on the shifts roles

and relations amongst four parties during the creation of the choreography in staged digital dance: choreographer, media designer, dancer, and technology. By examining these shifts, I aim to show how technology functions as a performing element onstage and as a dance partner in staged digital dance.

STAGED DIGITAL DANCE

One of the most significant changes resulting from the fundamental role played by technology in staged digital dance is the introduction of the media designer as co-creator to the choreography, in collaboration with the choreographer. It is important to underline that, in staged digital dance, the media designer takes part in the creation of the choreography from the very start of the process. Hence, the introduction of the media designer as co-creator from the very beginning marks a difference of the artistic status of the media designer from that of the supporting staff, such as light designer. Whereas technology and other supporting stage elements are most often created when the choreography is finished, in staged digital dance such a linear and independent mode of working during the creation of the choreography is problematized. Hence, the status of the media designer as co-creator in the artistic process can be understood as a symptom of a change in the understanding of the role of technology in dance: no longer as a supporting device but as a central element in the choreography.

What follows, the introduction of the media designer in digital dance requires a shift in the position of the choreographer, which involves the distribution of the choreographer's creative authority. Richard Povall argues that the emergence of digital dance was possible within the context of a new "paradigm of collaboration." [8] For Povall, this newly emergent art form of digital dance fundamentally changes the distribution of power structures and roles both within the creation and the exhibition of the performance. Povall argues that digital dance performances require the choreographer to hand over the omnipotent role he or she enjoys in non-digital-technology based dance performances in favor of a more egalitarian, collaborative relationship primarily with a computer programmer. [9] This new paradigm, according to Povall, stands in direct opposition to the conventional working paradigm in which the supporting disciplines, such as the lighting or sound technician, bring their separate pre-designed parts to the table as and when the choreographer requires them to do so. [10] Translating Povall's points to the argument of this paper implies that technology no longer functions as an add-on in the creation of the choreography in staged digital dance. Rather, technology functions on a higher level, as a performing element in the choreography to the extent that it requires the expertise and creativity of the media designer, alongside the creativity of the choreographer.

The crucial role of technology in the creation of the choreography requires new ways of working from the choreographer and also from the dancer. Whereas in choreographic practices in which technology functions as a supporting element a basic knowledge of the effects provided by technology is sufficient, staged digital dance requires a more detailed understanding of the technical system from the choreographer and dancer. In turn, the thorough understanding of the technical system required from the choreographer and dancer signals the dissolution of the staging of technology and the human dancer in a non-relational manner within a hierarchy of perceptual importance.

Johannes Birringer (2008) states that, most often, the understanding of the operations of the technology necessitates additional training from the choreographer and the dancer. [11] The additional training required from the choreographer and dancer usually takes place before the rehearsals. It may take the form of workshops or informal gatherings in which the media designer demonstrates the technology to the choreographer and dancer. In the case of *Glow*, for example, choreographer Obarzanek and media

designer and programmer Frieder Weiss met before the creation of the choreography. This was necessary because it was important for Weiss to understand the choreographic concept that Obarzanek aimed to achieve. In the same manner, Obarzanek needed to understand the way the technical system operates as well as the aesthetic possibilities offered by the technology. For Obarzanek, this was necessary because just as one needs to get acquainted with the strengths and weaknesses of human dancers, one also needs to get to know the strengths and weaknesses of the technical system:

The system has an inherent quality to it and a particular way of existing. For me as a choreographer it was really important to understand that and work with that. For example, the system is never completely still and stable; it always has this little movement to it. [...] The technology brings a kind of 'frequency' into the choreography that you'd normally never really have in a dance work. It has an aesthetic-kinetic quality to it that is in the nature of the machine. [11]

Hence, for the choreographer the understanding of the operations of technology—its potentials and limitations—is necessary because it leads to effective collaboration with the technology, as a performing element in the choreography. It also demonstrates that technology is now understood as a dance partner for the human dancer.

In sum, in staged digital dance, it is important for the choreographer and also for the dancer to understand the operations of the technology because the potentials and limitations of technology shape the choreography to a certain extent. Erin Manning (2006) underlines that the use of interactive technology in dance results in a reduction of the quality and tempo of the physical movements of the dancer. [12] She explains that a fully actualized (visible and complete) movement is necessary for software detection, usually by accentuating the extremity of the body (for example, by prolonging the arm or leg movements) or a displacement of the whole body across space. Therefore, technology conditions the choreography because it generates a preference for fully actualized movements rather than small ones. Moreover, Manning underlines that video-based motion-tracking systems require the dancer to slow down the tempo of the dance movements because slow movements can be better tracked by the system.

Certain scholars, such as Manning, are critical of the integration of technology in digital dance because technology conditions the choreography and restricts the physicality of the human performer. Yet this criticism can also be read on a different level—that is how the integration of technology functions as a dance partner on the basis of its influence on the choreography. From this perspective, which is the point of view of this paper, the restrictions brought by the interactive system are useful to understand how technology functions as a dance partner for the human dancer.

Hence, with staged digital dance, the interrelation and interdependence between technology and the human dancer, which has mostly remained hidden from the perception of the audience in the history of dance, is laid bare in the aesthetics of the choreography for the perception of the audience. In digital dance, technology moves to the center of the stage, alongside the human dancer. Moreover, staged digital dance portrays human and technology in a dynamic relationship with each other. This implies that, within the art form of dance, we need to expand the evaluative criteria of performer and performance to include technology and technological performance.

THE SPECTRE OF ANONYMITY

Seda Gürses

In dystopian debates on digital privacy, it is suggested that privacy can only be protected if we hide our personal information or practice control over it. In my paper I will look at the strengths and weaknesses of anonymity in each case, both as a technology as well as a strategy. I will also delve into its relationship to control, meaning how it evades and replaces different forms of control.

Anonymity is a powerful concept and strategy. It supersedes concepts such as authorship and origin, and manifests itself in our songs, poems, oral histories, urban legends, conspiracy theories, chain mails... For centuries, communities have used anonymity to articulate their collective voices. Anonymously produced statements or artefacts have expressed the cultural practices, beliefs and norms of the past, while creating a space in which to collectively build the future.

Anonymity allows the individual to melt into a body of many, to become a pluralistic one, for which the act of communicating a message is more important than the distinction of individual participation, be it at a demonstration or a football match. Yet, the seemingly unbreakable bond is fragile, since participation in the anonymous is fluid and is organized in a distributed manner. The anonymous perseveres only as long as the common line is held, hence at any point it may experience dissonance and simply dissipate. It is hence the volition of its participants that distinguishes anonymous groups from other types of collective bodies.

Anonymity is a means, never an end in itself, and can be utilized in unexpected ways. For example, in centrally organised forms of anonymity, e.g., military, corporation, participation in the anonymous is mandatory, individual actions are heavily controlled. The objective is still to protect, though the ones being protected are not necessarily the participating individuals but the existing power hierarchies.

The power of anonymity in communications has long been recognised by computer scientists and hackers. Anonymity is hence also a strategy on the Internet. So I ask, how is anonymity implemented, why, and by whom? What are its strengths and limitations?

'Anonymous communications' technologies like TOR, strip messages of any information that could be used to trace them back to their senders, so that a set of individual communication partners are not distinguishable. Observers cannot determine who is communicating with whom, so that individuals are protected against any negative repercussions resulting from such disclosure.

The architecture of the Internet makes it plausible to track the data bodies the users of the Internet leave behind, approximating all actions to their individual authors in physical space and time. These data bodies are open to scrutiny, dissection and re-use by collecting parties. By masking the origin, anonymous communications channels protect the individuals who authored these data bodies.

Despite the diversity of the groups and communities using anonymous communications, such technologies are usually cast in a negative light in policy papers and in the media. Anonymous communication

infrastructures are seen as providing channels for criminal activity or enabling deviant behaviour. But perhaps what bothers authorities most is not the fact of anonymity as such, but rather the user base and the distributed organization it relies on. After all it is obvious that data miners and regulators are keenly interested in systems that generate another type of anonymity, database anonymisation, a technique that is instrumental to the growing data economy.

The ideology behind the current data-driven economic hype suggests that the data collected will make the behaviour of populations more transparent, easier to organise, control and predict. Massive datasets are expected to reveal ways of improving the efficiency of markets and systems of governance, by applying statistical analysis methods to these datasets to infer knowledge. According to behavioural advertisers and service providers, these datasets will become 'placeholders' for understanding populations and allowing organisations to provide them with refined individualised services. In the process, elaborate statistical inferences replace 'subjective' discussions, reflections or processes about societal needs and concerns. The data comes to speak for itself.

However, collecting and processing such massive amounts of data is historically linked with a serious privacy problem. This is where database anonymisation provides a protection. The database can be manipulated in such a way that the link between any data body included in the dataset and its individual 'author' is concealed, while the usefulness of the dataset as a whole is preserved. If this is somehow guaranteed, then the dataset is declared 'anonymised'. Inferences can be made from the dataset as a whole, while ideally no individual participant can be targeted. This approach is endorsed not only by data miners, but also by regulators. The EU Data Protection Directive [1] includes a clause that frees anonymised datasets from regulation.

Once the link between the original author(s) and the message is broken and the message is released, it is likely to be subverted and reclaimed by others. This is one of the charms of the anonymous message: any individual or group can claim it as their own. But when a group subverts the message to negate all other linkages and continuities, monopolising the interpretation of the message's senders, destination and content, the relationship between 'the anonymous' and the message can get lost.

An example of this is given by Adela Peeva in her documentary film "Whose is this song?", [2] where she searches across the Balkans for the origins of an anonymous folk song. In each country or region she visits the song changes, becoming a love song, a song of piety, even a war song. Each variation comes with conflicting claims about the song's 'true' origins, all of which attempt to separate it from its nomadic past. The song is invariably re-shaped to uphold the local collective memory, as well as the community's future identity, in mostly not-so-subtle stereotypes: young Turks, amorous Greeks, proud Albanians, pious Bosnians, debauch Serbs, superstitious Roma, unflinching Bulgarians...

The film captures the dilemma associated with any anonymous action or artefact. Anonymity allows the articulation of a collective message. The message travels, free from the burdens of origin or authorship. However, this freedom is limited when a specific group claims the message as its own, and bends the message to suit its own interpretation of the past or future. The anonymous message can then boomerang to hit its collective authors: the hijacking of popular uprisings by a small group establishing its power, the re-writing of folk songs into chauvinistic hymns, or using anonymous actions as a pretext to introduce draconian security measures, are all examples of such de-contextualised anonymous messages.

In the data economy, the anonymised dataset becomes a digital mirror of the population's activities and tendencies. Organisations that hold a monopoly on these datasets assert their own categories of (un)desirable activities, in order to improve their markets and forms of governance. Since such datasets are anonymised and cannot be linked to individuals, privacy is supposedly intact (though anonymisation techniques provide no formal guarantees) and so the general population is not expected to question the ways in which the anonymised data is used.

We have seen how anonymity can be used to collectively protect individuals against Internet surveillance. But we must also recognise how similar strategies are being used to create discrete, decontextualised (yet linked) datasets that are essential to the data economy. We now have huge databases of 'friends' who rate, tweak and 'like' information which can then be used to guess our interests, desires, passions and weaknesses. The goal of the anonymisation of these databases is not to protect individuals, but to make it impossible for them to understand, scrutinise or question the ways in which these datasets are being used. We must cherish anonymity as a strategy for protecting individuals online, while rejecting its reincarnation as a tool to separate us from datasets being used to manage our lives.

Anonymity will always remain a powerful means of achieving political objectives and spreading collective messages. However, especially in political contexts, the vulnerability of the anonymous means that multiple strategies should be used to create a continuum of anonymously initiated activities. This includes making political statements that are explicit and precise, sometimes anonymously, sometimes not.

FLOSS CULTURE

Adnan Hadzi

This paper continues the debate raised in the Next 5 Minutes media conference

FLOSS Culture

In 1985 Richard Stallman formulated an alternative to, some might say resistance against, the practice of locking away computer source code through the use of copyright: *The GNU Manifesto* (1985). In *The GNU Manifesto* Stallman advocates four major freedoms for anyone engaging with Free Software:

- 0) The freedom to run the program for any purpose.
- 1) The freedom to study how the program works and adapt it to your needs.
- 2) The freedom to redistribute copies so you can help your neighbour.
- 3) The freedom to improve the program and release your improvements to the public, so that the whole community benefits (1985)

Stallman went on to write the first 'copyleft' license, the General Public License (GPL), arguing for access to source code as a basic "human right", by paraphrasing the Bill of Rights of the United States stating that "the ethical response to this situation is to proclaim freedom for each user, just as the Bill of Rights was supposed to exercise government power by guaranteeing each citizen's freedoms" (2001). The GPL as well as the Open Source Definition (DiBona et al. 1999, p.171) are often referred as the roots of the 'copyleft' attitude, also applicable to non-software information, which in the hacker lexicon the jargon file (Raymond & Steele 2003) is defined as:

copyleft /kop'ee-left/ /n./ [play on 'copyright']

- 1. The copyright notice ('General Public License') carried by GNU EMACS and other Free Software Foundation software, granting reuse and reproduction rights to all comers (but see also General Public Virus)
- 2. By extension, any copyright notice intended to achieve similar aims (Raymond & Steele 2003)

Copyright asserts ownership and attribution to the author. Copyright protects the attribution to the author in relation to his/her work. It also protects the work from being altered by others without the author's consent and restricts the reproduction of the work. Copyleft is not an anti-copyright but rather an extension of copyright: it includes copyright through its regulations for attribution and ownership reference to the author. Nevertheless, it also extends copyright by allowing for free re-distribution of the work and, more controversially, the right to change the work if the altered version attributes the original author and is re-distributed under the same terms. A user can exercise those freedoms provided that s/he complies with the conditions of this license. I would argue that applying such copyleft licenses to media productions is a possible strategy for enabling media and arts practitioners to engage in collaborative production processes.

For the copy-paste generation, copyleft is already the natural propagation of digital information in a society which provides the possibility of interacting through digital networks. In doing so one naturally uses content generated by others, remixing, altering or redistributing it. At the same time the Debian project, an independent decentralised organisation of mainly computer coders, argues for 'copyleft' over 'public domain' as the latter is not a good alternative to copyright, "because some will try to abuse this for profit by depriving others of freedom; as long as we live in a world with a legal system where legal abstractions such as copyright are necessary, as responsible artists or scientists we will need the formal legal abstractions of copyleft that ensure our freedom and the freedom of others" (1997).

It is not only corporate companies who strongly enforce copyrights, but also established artists and writers who are afraid of losing their position: "Plagiarism and piracy, after all, are the monsters we working artists are taught to dread, as they roam the woods surrounding our tiny preserves of regard and remuneration" (Lethem 2007)^[2]. The fear of copyright infringement often derives, not only from producers and publishers who are making most of the profits from sales of intellectual property, but also from writers and artists fearing their 'bread and butter' will vanish if shared freely. Linda Smith even argues that copyright is an extension of colonialism. Smith explains that the 'project modernity' ended the absolutist society (feudalism), and it signaled the beginning of the 'modern' state. This new state system, being born out of the industrial revolution, had to fulfil the requirements of the ruling economic forces. According to Smith, a system of ideas started to focus on self-interest and on a state system that had to regulate a "public sphere of life" (2006, p.59)^[2]. With this system being accepted, liberalism and the ideology of individual autonomy and self-interest ideas could be discussed in academia, especially the 'scientific exploration' of the rest of the world by Europeans. The 'modernist project' was born with the systematic exploitation of indigenous people in the 18th and 19th centuries. "The production of knowledge, new knowledge and transformed 'old' knowledge, ideas about the nature of knowledge and the validity of specific forms of knowledge, became as much commodities of colonial exploitation as other natural resources" (Goonatilake 1982)^[2]. In *The Contestation of Code* Berry argues for an analogy between code and law:

As technology increasingly colonizes and structures more aspects of our lives it is becoming increasingly important that the constitutive nature of technology as socially shaped is recognized (Kesan & Shah 2002)^[2]. If computer code is analogous to law (Kesan & Shah 2002)^[2], then it is clear that without some form of democratic accountability the code-based regulation of human behaviour will continue to lack legitimacy (Habermas 1988)^[2]. It is ... an important challenge for wider society to recognize that values are being instantiated within technological forms that can and should be contested before they become sedimented. (2004, p.83)

In that regard intellectual property (IP) law seems to be a romantic idea for authors of computer code, but more and more also for authors of texts, as well as media and art productions, because most authors have become nothing other than employees, the profits go to the software and media moguls, and the big moguls lobby for the extension of intellectual property laws. Proprietary software is an exercise in power politics because the IP laws grant firms power and control over the programmers and the users, and only a “few make the basic software decisions for everyone” (Stallman & Kuhn 2001). A possible alternative to this exploitation of authors might be through the principles of attribution and share-alike, meaning “that while creative work may always be copied, modified and synthesised into new works, previous creative work is valued and recognised by the community for its contribution to creativity as a whole” (Berry 2005, p.4)². Furthermore the FLOSS movement could regain control over projects through the use of componentisation which “is the process of atomising (breaking down) resources into separate reusable packages that can be easily recombined” (Walsh 2008). More and more technology shapes our social lives, therefore the discussion around the constitutive nature of technology becomes an issue. “Introducing democratic accountability to code may well be the democratic challenge of the twenty-first century and steering the implementation of technological artefacts will increasingly contribute to our ability to keep our future open and democratic” (Berry 2004)².

This could signify a *Culture Without Commodities* (Stalder 2002). To a certain degree this is already being practised within the fields of music and software programming and some forms of cultural production (such as avant-garde, underground, DIY-movements, parts of academia and Open Source movements) that are not selling objects. The motivation of those groups is not the commerce, but the recognition, often by limited numbers of people, that the exchange between peers is the vital part of a culture without commodities. FLOSS culture, which extends into net culture, is more than about what happens between people and networks. In *Free Software as Collaborative Text* Florian Cramer argues that FLOSS is a “rare example of electronic literature which does not confuse the Internet with web browsers” (2000)². As FLOSS is a non-rival, non-excludable good it cannot be sustained according to conventional market logic. Paradoxically it is being sustained, exceeding often “the capabilities of conventional proprietary, binary-only software” (J. Boyle 2003, p.44)². But for Chris Atton it “seems that the dominant regimes of copyright and intellectual property relations are unlikely to be replaced by a new model based on social authorship. At best, these practices of file sharing on the Internet appear as marginal interventions that can do little more than chip away at the enduring and limiting logic of capital” (2004, p.110). In that sense we might soon be witnessing a disappearance of public spaces in cyberspace, as happened with urban public spaces. Urban public spaces were planned in the form of parks, squares, and promenades. These spaces served for people to meet, communicate, exchange ideas, and expose themselves to diversity. But today urban public spaces frequently do not support this freedom any more because often they are privately owned places, like shopping malls, which can prohibit any action that hinders the consumption of commodities, such as demonstrations.

Remember that a 'boulevard' was originally a walk planted with trees which circled the town and usually occupied the space where the old ramparts had been. (Perec 1974)

On the other hand, digital networks provide new possibilities for participatory media practices, especially through the use of Free Software. Since art and ideas never develop within an art-historical vacuum but always feed on the past, Free Culture promises to make our cultural heritage accessible to everybody to re-read, re-use and re-mix as they like, “without open access to the achievements of the past there would be no culture at all” (Medosch 2003)². Participatory culture often ignores or violates copyright restrictions that might apply to media artefacts or software employed; this form of 'piracy' and sharing can be perceived as a cultural statement.

*But one ought have a critical stance towards the notion of the 'free', because 'free' is included within the economic system and, as such, file-sharing is part of the economy. Free production, as well as sharing, should be an option, allowing for experimentation, and “producing culture with other economic models, on a global scale” (Lovink & Rossiter 2006). An example is the academic AAAARG file-sharing network: an effective distribution system in terms of its scalability, openness and durability – only made possible, however, as a conglomerate of both human and non-human agency. In fact, file-sharing can not only be used for distribution, but for actual collaboration and production. In that sense a legal system, social contracts, aiming to control the data spheres, needs to be tailored carefully because “sharing” a file is not equal to “sharing” in the physical world, it is rather facilitating the copying of that file (Logie 2006, p.85). In his research on file-sharing, Jonas Andersson refers to the situation as being controlled by the most driven producers and consumers, and further states that the old distribution model is so impoverished that it chooses the safest route, “the most bland of bets” (2009b). Boyle warns in *Guerilla Television Revisited* (1997) of the pitfalls of participatory media. For Boyle historically such cultural statements, coming from media and arts collectives and their participatory media practices, have often been absorbed and used by mainstream media, paradoxically the very institutions these collectives resisted and tried to change.*

I further argue that the windows of opportunity emergent digital networks are currently offering might be short lived, especially the potential of decentralised distribution technologies such as file-sharing. Due to current changes in legislation we see the first examples of digital networks being formatted and regulated, for example the blocking, and many argue the censorship, of websites offering access to decentralised distribution technologies. FLOSS culture therefore might allow for a new legislation, as well as alternative licensing schemes and open contracts offering participatory media producers a possible legal framework. Thus applying the notion of 'social contracts,' the notion of open and distributed sharing can be reinforced as an overall heuristic and social ethos.

Seen in the light of media moralities media production for the welfare of others challenges the ideological belief in the 'individual' having to succeed. When sharing code (Himanen 2001), media, art and culture in general, it is ultimately a challenge to one's own ego, and it is also a subversion of selfishness. Arguably our drive to own property, or in the context of FLOSSTV 'intellectual' property, makes us underestimate the difficulty of engendering a greater compassion in ourselves for those we live with and share our lives with— basically the society we are part of:

The purpose of property is to ensure a propertyless class exists to produce the wealth enjoyed by a propertied class. Property is no friend of labour. This is not to say that individual workers cannot become property owners, but rather that to do so means to escape their class. Individual success stories do not change the general case. As Gerald Cohen quipped, 'I want to rise with my class, not above my class!'. (Kleiner 2007)

Everything we consider we own is always dependent on others. Any intellectual property (and indeed all cultural production) is based on others' efforts, dependent on others' labor, dependent on audiences supporting one's own production. Intellectual property becomes interdependent. If we accept that the welfare of others is as or even more important than our own welfare, if we accept that we all have equal rights, we can decide that intellectual property is unjust, or, to paraphrase Pierre-Joseph Proudhon (1840), that *intellectual* property is theft.

Without becoming aware of and challenging one's own greed and selfishness there is no progress towards 'social' media. The novelist Norman Mailer stated that "the only way socialism can work is if there is ... some larger sense of things. [Otherwise] you just get the play of egos" (Quoted in Bellos 1997). My view is that any FLOSS practice needs to analyse its motivation in order to overcome ignorance of greed, and that "it is not enough to address ignorance with political argument, because anger and greed are an active form of ignorance - they repel counter-arguments. If we are to open minds, we must also open hearts" (Edwards & Cromwell 2009, p.251). Engaging with FLOSS practices then becomes a virtuous action, an ethical practice. *A spiritual master, Śāntideva, once wrote in the 8th century: "All those who are unhappy in the world are so as a result of their desire for their own happiness. All those who are happy in the world are so as a result of their desire for the happiness of others. ... Note the difference between the fool who seeks his own benefit and the sage who works for the benefit of others" (1997).*

ARCHIPELAGOS OF ART

PETER HAGERTY

The paper considers the rapidly growing metaverse and its implications for a post industrial society with particular reference to the new art forms specific to this new medium.

Today the internet is the backbone of the global economy and without it our industrial infrastructure would collapse within hours, but a decade ago people would ask “Why do I need a website?” Today nobody asks that question, they may prefer a Blog or Facebook page but whatever format they choose an online presence is a recognised door which connects to other people. Today the contemporary question is “Why do I need a virtual world?”

During the period the web came to dominate the media landscape there was also a parallel development of virtual environments, commonly seen in the ubiquitous games for the Sony Playstation or Microsoft's X-Box. For most children in the western world these games have come to dominate their leisure time, gone are the toy soldiers and masquerade of 'cowboys and indians' the arena is now a virtual theatre of war where every kill is a point.

There is however a lesser known type of virtual environment which is distinguished from the aforementioned games- which are characterised by agreed movements, a defined outcome and usually in terms of one player or team winning. In contrast these other virtual environments are self authored and initially present an empty world, a *tabula rasa* where an author can create whatever he or she wants and if rules are to be used that is the authors choice.

The example of Second Life (Linden Lab 2005)[1] provides a good introduction to the possibilities of self authored virtual worlds and there are now many similar examples in the rapidly growing worlds of Open Simulator [2] where the term metaverse is used to describe a collection of virtual worlds - rather like continents which are connected to each other with the ultimate goal of creating an internet scale virtual environment network.

The word which most characterises the virtual environment is immersion, virtual environments are immersive environments. When we read a novel we immerse ourselves in the story and empathise with the struggles of the heroine or anti-hero and the dramatic arc of their lives on the page. For the duration we allow ourselves a willing suspension of disbelief in that while we know the events in the story are not real we allow ourselves to believe they are. The same pertains to cinema, particularly in the genres of the thriller and horror, these are ancient pleasures which earlier generations had similarly sought in theatre, opera and epic poetry.

Imagine then that instead of sitting in a comfortable chair, fingers tense with fear, watching and empathising with the on-screen character – that instead you are the character! This experience is already familiar to children in their war gaming where the psychological response to such immersion, the feeling of actually being there is very intense.

The rapid growth of virtual environments has prompted psychologists to ask why? What is the attraction? The evidence from surveys is complex, [3] but anecdotes suggest, for the game players at least

that a common reason is “Because real life sucks”, a sad finding perhaps but most of us would recognise some truth to this and further we would not be surprised that a university educated supermarket shelf stacker would, rather than stacking shelves, be a knight on horse back with his damsel avatar by his side leading fellow warriors into battle to defeat a deadly enemy? Oh but that is only fantasy you say, he is dreaming and indeed he is. But isn't escapism the *sine qua non* of the novel and cinema? Recollect the rebuke at the end of the nineteenth century when people remarked of a friend “Oh she is clearly not well, she spends all day at home reading French novels.”

Escaping into virtual worlds offer an escape for those who find the real world insufficient to their needs and while living a surrogate life as a medieval knight might not be your choice, a more disturbing ontological question is “If you could live in a world that was just the way you wanted it to be, with specifications you'd chosen, customized and personalized to meet your every need and fulfil your fondest desires, would you spend all your time there? Or would you prefer to stay here, in the real world?” [4]

Fundamental to this enterprise is that the avatar is an abstraction of its owner and frequently a person's avatar is an idealised visual representation of them self, a remodelling based on vanity but also, with the potential for some, to bring a beneficial change in how they can socially interact.

We discriminate on the basis of sex, race, colour, we judge people on their looks, their able bodied-ness and their age. If the base causes for our prejudice could be removed, to create a more level social playing field, would this correspond to an improvement in social well being?

In a virtual world the avatar of an isolated house bound eighty year old person could look like a thirty year old who could – in world, talk and interact as an equal again. A hospital bound patient, a paraplegic, the extremely shy, those without the power of speech anybody who can use a mouse can find in a virtual world a new place for social interaction. Let us be clear, this is not an either or situation; nobody lies in bed reading French novels all the time.

War gaming is the first and seminal example of online role playing, less complex than Aeschylus' reworking of Herodotus it is also the simplest because players don't need a 'character', they merely require to know their allowable moves and how to take an opponent out of the game. But if the motivations are not as simple as kill or be killed how is dramatic structure established? Actors in theatre and film are aided by a script describing the actions, plot and characters, in role play these crucial narrative devices, excepting the character, are not available. This is the realm of the highly literate paragraph role players where a loose plot is perhaps agreed in advance but all the dialogue is written on the fly.

Clearly the 'killer app' of virtual worlds is interactions with other people and while the potential for duplicity is a given we also know that we are in the realm of theatre. As Vernant remarked “In the case of Dionysus, the mask disguises him as much as it proclaims his identity.” [5] The avatar is our mask and like the mask in the Baccic rituals and the festivals of Carnival it offers a temporary release from the mundane. The mask offers liberation, a device for fiction which explains why role play of a sexual nature is common allowing individuals to explore psychological danger from a safe distance.

Other aspects of virtual worlds offer new opportunities for visual artists particularly photography, animation, machinima and virtual sculpture. The virtual camera presents an entirely new tool for a new subject, the *mise en scène* of virtuality. In parallel with still photography there has been the rapid growth

of machinima, the use of real-time 3D computer graphics rendering engines to create animated cinematic productions which will in the coming years transform advertising, promotional video and cinema.

There is another genre of art which is unique to virtual worlds, an art of such originality that it rarely reaches the museum visitor. Part of its description would be virtual sculpture, abstract compositions of prims, textures, particles, transparency, phantoms and physics where space itself is a plastic dimension. One struggles for a language to describe these conceptual and immaterial works in which an amalgam of technical finesse and aesthetic sensibility combine to demonstrate a pure digital craft .

Many virtual world artists use scripted code for contributory effect in abstract works to describe possibilities, others embrace the language of virtuality with formal composition and audio while others use virtual art to reflect upon the real world. Social, dramatic, aesthetic and conceptual the virtual worlds are ground breaking, the avant garde is alive and well and living on the archipelagos.

THAT STRANGE FEELING

IAN HAIG

The uncanny as defined by Freud is that which is uncomfortably strange finds a special kind of resonance with various kinds of technological media. This paper discusses how different kinds of technologies can evoke the uncanny, while tracing the emergence of electricity as a kind of uncanny phenomena to more contemporary instances of the technological uncanny in the work of various artists and other assorted pop cultural references.

Technology has long had the ability to evoke and bring to life notions of the uncanny, the history of electricity itself has been associated with the territory of the inanimate and animate in a variety of ways. A catalyst for a state between that which is living but should be dead, the familiar made unfamiliar, together with providing aesthetic feelings of dread, horror and given to feelings of distress.

Perhaps one of the most striking and memorable experiences of the uncanny and electricity occurred on a personal level on visiting an exhibition with my at the time one year old daughter featuring the work of artist Tony Oursler. On entering the darkened room of the gallery and upon seeing one of Oursler's familiar 'electronic effigies' of projected video onto a small mannequin, all was calm as both myself and my young daughter contemplated Oursler's piece. However once the video started to move and talk, my daughter let out a blood curdling scream of sheer and all consuming terror, which I haven't witnessed since. Clearly she was disturbed by what she believed to be an inanimate object, ie: a doll, suddenly come to life, however the uncanny effect was more so seeing her react in such an extreme and distressing way.

The experience on viewing the Oursler piece with my child, became doubly uncanny, his work was already playing with notions of uncanniness, of the inanimate made animate through the ethereal and ghostly effects of video projection onto anthropomorphized dolls. The intense emotional reaction my daughter had on viewing Oursler's piece was as if she herself were possessed. Such an episode recalls Freud's notion of epileptic seizures and of madness having their origin in the uncanny, of the body being momentarily taken over or possessed, indeed the middle ages saw such behaviors as ascribed to demonic influences. [1] Like the prisoner on death row, their body on the receiving end of 2500 volts, the epileptic seizure is uncanny in its appearance, in recalling the violet surge of the body electrocuted, electricity not as the spark of life, but death. The epileptic fit a kind of uncanny living death, that one recovers from. As the body slips over into another state of being, the nerve cells that transmit electrical impulses of the brain, momentarily disrupted.

For Freud the doll holds a special place in the corridors of the uncanny, in particular when dolls appear alive. [2] Freud has outlined children live in an animistic world, where the line drawn between living things and lifeless toys is a blurry one. Children engage with their dolls as if they were alive, while adults are often unsettled by things that oscillate between life and death, as the doll, or mannequin momentarily appears as a living entity, activating our uncanny senses.

1890 saw the release of one very strange and uncanny doll indeed, known as Edison's talking doll. The doll featured a miniature phonograph embedded inside. These "talking" baby dolls were possibly the

first attempt at using sound technology in toys. As Gaby Wood has pointed out, the capturing and reproduction of speech in the early phonograph was integrally linked to finding a casing for it in human form. [3]

Edison's talking doll however was a disaster for the inventor, production delays and poor recording technology and damages to the toys when they were distributed. Combined with a recording of a voice that sounded entirely strange and otherworldly, which did more to creep children out. Edison would later refer to the dolls as his "little monsters".

Erik Davis too has pointed out today's realistic "Real Baby" dolls are a weird mix of servo motors, electronics, and that imaginative zone of the uncanny. [4] Programmed to simulate real infants, The Real baby doll, can poop its pants and fart, as basic bodily functions take on a strange, electronically mediated life for their attentive real life baby mothers.

Mark Dery sees "The Home Shopping Network's Gallery of Dolls as a televised infomercial for Freud's uncanny", featuring an array of disturbing, lifelike collectible porcelain dolls. Their transfixed gazes frozen for all time in a "queasy mix of sentimentality and side show grotesquery" [5] glaring at us through televisions unflinching electronic stare.

From televised transmissions of the uncanny doll and uncanny sound technology to the uncanny phenomena of electricity itself. In 18th century England electricity was an ongoing preoccupation with many. Benjamin Franklin the American politician and inventor, presented a paper in 1751 at the Royal Society putting forward the idea that lightning was an electrical force. As the new world was being discovered, so too was the discovery of various new and exotic animals, one of which was shipped to London in 1774: The electric eel. Combining the absorbing preoccupation of the uncanny wonder of electricity together with the strange, and almost otherworldly new species which could emit an electric charge. The electrical eel also saw the bizarre and popular craze in London of 1775 of electric eel parties, which saw gatherings to see how many people could feel the electrical eel charge, as people joined hands shocks would be felt by all. [6]

The technological uncanny too finds its home in medical equipment, devices for keeping the body from slipping over into death. The medical machine infused with a high degree of uncanniness and certainly downright creepiness as Bruce Grenville has pointed out is the iron lung. [7] The machine embrace of the iron lung, once the only way to assist individuals whose chest muscles has become progressively damaged by polio. The Iron lung has many connections to the uncanny, the undead body being kept alive by the assistance of a machine designed to expand and contract the chest. Not to mention the associations of the machine and its relationship to the unsettling fear of a horrific and devastating infectious disease, as if somehow the iron lung embodied the disease of polio within itself. However perhaps it is the notion of the iron lung as a kind of perverse cyborgian architecture, the notion of the body being controlled by a force outside of itself.

Andy Warhol's Big Electric Chair from 1967, also understands the idea of a technology that can embody an unsettling quality and provides us with an aesthetic quality that arouses a feeling of absolute dread. Warhol's iconic image revealed that aspect of the uncanny, where something is seen which is normally hidden from view: Death by electrocution, planting the seed of the electric chair in the popular consciousness as a technological object imbued with a devastating fear.

Electricity can create life, as easily as it can destroy it, capable of transforming the inanimate into the animate and back again. For some time too it was believed it could also heal the sick and the diseased. Electrotherapy has a long history in early 20th century medical practices, in particular the galvanic bath, of soaking in electricity infused bath water for a cure all. To electro shock therapy, now renamed as Electroconvulsive therapy, a psychiatric treatment in which seizures are electrically induced into the patients brain. Early electro shock therapy often resulted in extreme side effects, of seizures, and turning patients into a vegative state, as consciousness slipped over into that uncanny space between being alive and dead.

It is the Alternative Health fraternity that have carried the torch for electrotherapy in recent years. Which puts forward the belief that the human body is composed of negative and positive electrical energy, indeed all living matter carries with it an electrical charge. The appearance of the electrical zapper, for the user to wear, which literally zaps the users body with an electrical current to rid the body's internal organs of pathogens and disease, renders the body as an uncanny conduit for electrical impulses.

I sing the body electric and electricity as that life-force which one takes for granted, as a bringer of death, life, re-animation and health and perhaps most of all as an activator of that mysterious terrain of the imagination known as the uncanny.

SEAMLESSNESS IN THE ANALOGUE AND DIGITAL

Sigune Hamann

Sigune Hamann will discuss work on representation of movement, time and narrative structure through image manipulation with a focus on her process of capturing and reading the dynamics of urban environments in panoramic film-strips.

Introduction

As consumers and producers of contemporary visual culture, we are in an era of high-resolution photographic realism. Continuous hardware and software development simulate close up sharpness in images and hyper-real movement through zoom and panning-actions and enhanced playback technology. In counterpoint to this, I develop analogue film-strip imagery using a still camera in the manner of a movie camera that offers a different representation and a deconstruction of the way we see rather than the objects to be seen.

Reflecting on ideas of data disinformation, this paper will look at the representation of movement, time and narrative structure in film-strips, and examine shifts of information and overlapping, repetition and blurring of images as part of the analogue and digital process of production. It will reflect on ideas of seamlessness and continuity at a time dominated by fragmentation and layering.

Film-strips

PHOTOGRAPHY

In photographic film-strips I capture the energy of urban environments and the movement of people. This process of 'tracing' in film-strips involves using an analogue photographic camera like a movie camera. A whole roll of 35mm film is exposed in a continuous rewinding movement while I am also moving in relation to the subject. The celluloid moves past the lens in a cinematic movement, although unlike film exposed in a cine camera, time is not separated frame by frame but flows in a continuous exposure over minutes to produce one long panoramic image. Although the images are static, they contain the indexical traces of movement – of the film, the camera and myself moving within the optical field.

The hand held camera as an extension of my body and the performative process allow for elements of chance within the work. I intuitively respond to each situation, varying the speed of my own movement and of rewinding the film. Moving elements such as people register more clearly than static backgrounds, which dissolve into ambiguity. The movement of the camera parallel to the movement of the objects let them appear in repetition.

The speed of the rewind is un-even. Moments of slowing reveal the analogue photographic process; vertical lines due to momentary framing become visible. Accelerating the turning results in extensive movement blur. However the level of layering, abstraction and focus cannot be planned, only performed.

INSTALLATION

Digital technology allows the film to be scanned and seamlessly printed in large segments. Viewers can re-enact the time sequences chronologically in video animations or by moving along the images of large-scale photographs, from segments to 360-degree installations relating to the situation in which they were taken. Like fleeting mental images they are at the same time linked and freed from the event, the environment and action that they record.

The film-strip showing at this year's ISEA exhibition *Uncontainable: Broken Stillness* is a segment of a photograph taken in Whitehall in London last year, during a protest march against the increased student tuition fees. As a demonstrator at the march I captured the dynamics of students and fellow staff moving through Whitehall, chanting and waving banners and flags in a unified expression of protest. For the duration of the exposure the film is rewound past the lens in the hand-held camera, following the movement of the crowd. This process abstracts and compresses the action revealing both chaos and order, yet details are enough to fix the image as an indexical record of the actual event.

The imagery captures the moment described by Götz Großklaus referring to Elias Canetti, when multi directional movement becomes homogenous and when a common goal directs crowds in a common movement, physical and psychological — the moment when we are no longer in a crowd of strangers but in a crowd of 'equals': The movement of the crowd appears in short time stops and starts, in stagnation and continuation. [1] These rhythms and the compression and expansion in transit find their correspondence in the mechanical process of rewinding the film, hesitating and accelerating, and by the fluid density of the resulting imagery.

SEEING AND READING IMAGES

Film-strips are a result of a direct, perhaps pre-cognitive form of seeing and an experience of the duration of time, produced through mechanical and chemical processing. The images are referential and real with a clear pictorial definition within them while showing a general degree of motion blur.

An absence of language is suggested, while objects are present that refer to something apparently quite concrete. As conventional ways of seeing and reading images become less applicable, the representation of visual information in the film-strips becomes closer to the physiological process of seeing than the information itself.

We have learned to see and to understand visual data, to make sense of images in a subconscious process. It is part of an evolutionary development, processing visual input to concentrate on what's vital to us and builds images in our minds. The brain constructs images and seeks order to establish correlations, consistency and continuity. Images change with rapid technical developments, and our perception tries to adjust correspondingly. I think however that the discrepancy between reading an image as a form as it used to be and now experiencing it as an event, fragmented, layered and changing over time needs to be addressed, and that the change of conventions of processing this information is not quite as fluid as it might seem.

The construction of movement and seamless images in the brain depends on our sense of space. According to Wolf Singer the clarity of inner spatial images stems from an evolutionary development, defining the long-term memory mainly as a memory of places and their relationships. [2]

Conclusion

TIME AND CONTINUITY

The length of time represented in the film-strips is determined by its physical length. In terms of mathematical, continuously moving time a couple of minutes of an event are captured. Film-strips don't have beginnings and ends in terms of narrative; they are segments of an ongoing experienced time, the long format suggesting continuity before and after. These segments become like fragmented memories that represent situations or narratives within them.

Film-strips represent a unique sequence of time, but there is a sense of eternity also through repetition of movement, one film-strip written in panning movement over another, images and activities being replaced by others continuing an ongoing narrative. "In life we are accidental witnesses of certain events and images, whose duration in time we cannot control. That's why all art begins with the wish to fix a moment, and to make it last for a long or even infinite time. Only then will the viewers have endless time, that they need to determine duration and rhythm of their observation autonomously." [3] Time is embedded in the film-strips in a curious way relating equally to sequential moving images, sequential still images and single photographs. Although time is stopped, a moment is extended. As Andy Warhol described it in connection with his 8-hour projection *Empire one* one can "see time go by."

The film-strips are loops, particularly in panning animations or 360 degree installations. Loops create new meaning through fragmentation and seamless repetition of original data. As with patterns or a motif in music, the brain registers repeated elements. Loops are generators of form; they offer the possibility of infinite extension, continuity and the evasion of an ending.

"The art of today seems to have discovered a new endlessness. However we are not dealing with a renewal of a romantic aesthetic of the sublime, but the endlessness of the continuation of the always similar in small variations, the endlessness of a project of Continued-Life, that cannot be completed, but only left behind." [4]

BIOCYBRID ECOLOGY: ART, TECHNOSCIENCE AND LIVING SYSTEMS

CAMILA HAMDAN

The article is about two transdisciplinary art projects, developed in Brazil. These works were made by the augmented reality technology. In the first, the body tattooed with AR code, in performance art was connected in network for modelling winds. The second, an object modelling - 14BIS-, Santos Dumont's aeroplane was in the sky. These artistic works describe the reinvention of the environment by physical space and cyber data.

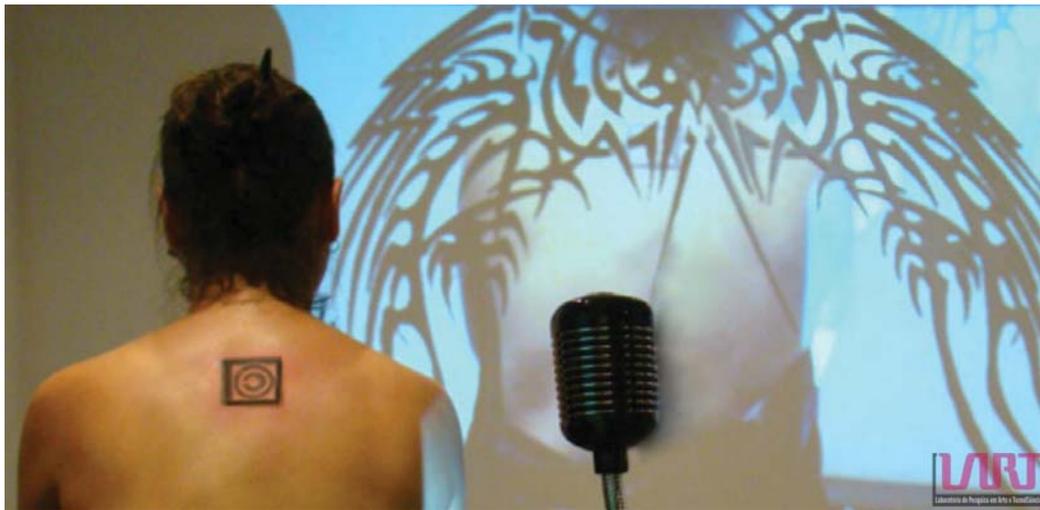

Image 1. Opened Body Connection. Computer vision system and projection of the wing actually increased from the tattoo.

Image 2: Opened Body Connection. Cyberperformance held at the Museum of Image and Sound/MIS during the IV International Festival of Mobile Creativity - Mobilefest on November 14, 2009, in São Paulo-SP, Brazil.

Image 3: 14 Bis airplane. Latin America Memorial, São Paulo, Brazil. September 2010.

Our goal in this paper is to describe the theoretical-practical context of our current production, developed in Brazil, in the Laboratory of Research in Art and Technoscience, that from a transdisciplinary approach offers us a new vision of nature and reality integrating concepts of Philosophy, Biology, Physics, Art, Computing and Engineering, as systemic parts of knowledge, in which 'all disciplines investigate the same issues, all sciences become a single science.' [2]

Thus, we find in Art and Technoscience a way that allows us to contribute with the reflections about the contemporary human being in the environment in which he/she lives. The challenge of relating art and software engineering, automotive, electronics and biomedical research at the Faculty of Gama, Brazil, is unprecedented in Latin America. To guarantee this, we rely on national agencies to foster scientific and technology research that enable the formation of human resources for research in the country. The partnership between the Government, companies and universities in which it begins, allows us to generate new ideas and suggestions that can contribute to our common goal of expanding knowledge of human possibilities.

The current scientific world has unveiled a new condition of life on the planet. We are increasingly concerned with the nature and the human being, thus, innovative possibilities of artistic creation emerge.

Studies that approach art, biology and technology research of artists and precursor scientists of the body dialogue as support, manipulation, speech, expression, and biological view and that overturned or challenged the physical, emotional and sensitivity limits of the human being concurrently with technologic developments of his/her time, have been of great importance for our research.

Assumptions of body art: visible and invisible imagination

The body in motion as a proposal to challenge the physical limits of the human being can be seen in the 'Manifest of Futurism' by Fillippo Marinetti (1909), which explores the notion of speed and strength in sculpture at the beginning of the twentieth century. The body that is represented there, crawls, fighting against an 'invisible' force which introduces the concept of time as the fourth dimension represented in a sculpture. The 'invisible' forces grounded in technological developments of this time, for example, the work *Unique Forms of Continuity in Space* (1913) by Umberto Boccioni, suggests the viewing and the tactility of informational data from an unseen force, where perception is not only in the hand, but on the whole body/mind complex that it touches.

Gestural actions are also noted in Pollock's *Action Painting* (1947), in which the visceral motion of his action, allowed to record information of the violence of his muscular body gestures through the paint on panels. Abstract art emerges then, as a painting from hand signals of the body as expressive means.

The paintings and conceptual objects of the 60s start the dialogue of the moving body, which soon become ephemeral artistic actions experienced in performances, *happenings* as social and conceptual criticism that relate the aesthetic art of the event and the human condition of the time. Yves Klein's (1960) female bodies as 'living brushes' contribute to the visual record of biological images, in a process of stamping anthropometry.

The principle of using the body as support and artistic expression also comes from the conceptual physiology of the *Body Art* (1960) movement, in which performing creations are developed with public participation, in places related to the concept of the presentation. Artists experience bodily limits of sensitivity and affection: pain, pleasure, discomfort, intimacy and happiness in intuitive, cognitive, basic and complex emotions in the performing actions.

Thus, the set of logical operations of the possibilities of human actions are considered as natural languages used in the analog art (op art and kinetic art, Fluxus, *happening*) with the intuitive use of the concept of algorithm (instructions to perform a certain task) leading to an explicit integration with the public. [10]

In parallel with the artistic manifestations, technological advances in programming languages, artificial languages or digital codes created sequences of signs in the form of letters of intuitive instructions from control systems, instruction and game rules. [10] It was with the mathematical, logical and cryptanalyst Alan Turing, in 1937, that the concept of algorithm and the area of Computer Science were created, by the *Turing Machine* through the computing devices designed to help investigate the extent and limits of what can be computed.

There are many trials and artistic provocations that test the limits of the human body and assign in experiential character, in performing and objectual actions, the visible and invisible imaginary, involving questions about life itself.

Today, seven decades after Alan Turing and much artistic experimentation, proposals for computing the sensitivity and affectivity of information through human body emerge. In this sense, we consider the concept of 'biocybrid ecology' we have proposed as a perspective of a systemic view of interaction, perception and cognition through practice and theory of techno-artistic that allows reengineering life.

Reframing of consciousness attained in the post-biological era, lived in the 'Cybrid Architecture.' [1] proposed by Peter Anders, where the properties of the informational data of the cyberspace are entered into the physical world we know, in which a new quality emerges, the cybrid, composed of contents added to the hybrid world of cyber data.

These are systems that allow a co-existence in a continuum between the virtual and physical reality endowed by an interface for vision and interaction. They hybridize the physical and digital spaces, simultaneously, overlapping them in a hybrid that becomes cybrid. [5]

In this sense, the important technological change, proposed by Mark Weiser, [9] is the one that fundamentally changes our lives from the place of technology. In this way, what really matters is not the technology itself, but its relationship with us. According to the author, in the last fifty years there has been in computing major investments in research on the relation of bodies with the technologies.

Today the Internet is taking us through an era of widespread distributed computing for the relationship of ubiquitous computing. It is the relationships and interrelationships of technology in our lives, in the environment and in our bodies, when shared between each one of us and the things of the world, everywhere, that ubiquitous computing has aimed to make the use of computers emotionally invisible to the user, making it available throughout the physical environment, subtly, characterized by the spread of properties that make the cybrid emerges.

The bonding of synthetic data to the real world creates scenarios by inserting the virtual to the real. This is the mixed urban life or mixed reality whose actions mix spaces that aggregate and paste information to specific locations. Mobile and locative technologies are used, pasting data on the reality to be viewed through devices such as webcams and/or cellphone cameras.

In this sense, we are going to describe the work *Opened Body Connection* as an artwork that uses the technology of augmented reality (AR), approximates the human body of the desire for ubiquitous technologies and contributes to new perceptions of reality, for the production, awareness and interaction of natural and artificial feelings as an integrated whole of the body in interaction with the environment.

For two hours, three-dimensional animations ranged the body being tattooed in a ritualistic moment experienced in the interstitial space between flesh and the cyber of data. On the back, the figure of the tattooed copyleft, as a marker of augmented reality that allows the machine to enter on it three-dimensional animated wings. In this sense, the marker makes a pun on the concept of copywriter, which is commonly used in reference to copyright, the intellectual works and their authors. Thus, copy-

left opens a new thinking that enables the copyright as a way to subvert the rules of copyright protection and remove barriers to the use, distribution and modification, in this case, of a creative work, demanding the same freedoms to be preserved in modified versions.

Opened Body Connection is an artistic proposal that alludes to the body without authorship, copyright, collective and artistic production with the use of free software and open source for the continued process. In this sense, the body is not unique, but open, built by multiple senses of the connection. They are cyber data flowing through it and beyond it in direct contact, invisible, tangible by the network sensations. A freedom to bend boundaries that transforms the organic into a cyborg body. Skin with a data cloud that are seen and experienced by the sharing of information. A cyber performance configured in the relationship between humans and the environment, a mixture of information, transmitted in real time by the Internet through streaming of sounds, images and texts in an interaction channel composed of social networks.

Another artwork that uses augmented mobile reality and geo tagness for mixed landscapes is *The 14 Bis Air Plane*. Expanded interactions and mixed landscape generated the *14 Bis* cybrid system, to celebrate Brasilia's 50th birthday, in a public event that explored mobile and locative interface in mixed reality. LART creative practice put in the Brazilian capital's sky the historical plane *14 Bis*, invented by the pioneer of aerospace engineering, Santos Dumont. The virtual plane in real scale (with a length of 15 meters) is geolocated in augmented reality, with the tag code placed in the satellite exploring the Global Positioning System and results into the data visualization apparition of the historical plane flying in the city sky.

Perception and cognition in the new human condition

Thus, the phenomenon of behavior and perception is, according to Merleau-Ponty, the first contact with the world that takes as its starting point the existential facticity, human phenomenal, doing a transformation of subjectivity, making the body the subject of perception. Similarly, ubiquitous computing presents a new approach to appropriate technology for our lives, called 'calm technology' [9] involving the center and periphery of human attention.

It is in the periphery that things are tuned by a large portion of our brain devoted to processing sensory peripheral to the notion of ecological perceptual possibilities [4] applied to the psychology of things. [7] It is the mixed environments that people are surrounded by intuitive interfaces embedded in everyday objects and around them.

The perception, according to Alva Noe [6], is not something that happens to us or in us, it is something we do. Consciousness of perception depends on the capacity of action in a physiological process of brain thinking, on the ability of the body as a whole. To perceive, according to this enactive approach of perception, is not only to have feelings, but it is to have the sensations that we understand. According to the author, the content of perception is not like the content of an image; the world is not given to consciousness at once, but it is gradually acquired through active perceptive exploration of the knowledge of the body.

According to the biologists Humberto Maturana and Francisco Varela, enaction is guided by the understanding of perception through the actions of the subject in space. 'To the extent that these local situa-

tions are constantly changing due to the activity of the individual perceiver, the necessary point of reference for understanding the perception is no longer a world previously given, regardless of the subject of perception, but the sensory-motor structure of the subject.' [8]

Cognition, in its structures, emerges from the sensory-motor experienced schemas that allow the action to be built and guided by perception. It is the experiential sensorimotor contextualized structure, 'the way the subject perceiver is written in a body, [...] determines how the subject can act and be modulated by the events of the environment.' [8]

By taking a creative capacity of operational intervention upon life on manipulations of its conception and procreation, the human being participates actively, in the perspective of evolution, of a process which could alter its nature.

The construction of techniques and production of tools have always followed the human phenomenon. The formation of man – anthropogenesis – coincides symbiotically with the technogenesis that the first tool of man was his own body. In this context, nature reflects the interdependence between anthropogenesis and technogenesis in an ecological way in a new human condition.

Oliver Dyens [3] examines the convergence of computing, communication and biotechnology into a new paradigm of information as a very important thing of what is happening with the 'human condition', that was thought to be essentially unchanged.

Physiology of the Emotions in biocybrid feel

Physiological data, image processing in expert systems are the basis of Biomedical Engineering, thus, a new concept of biocybrid emerges [2], reaffirming the body/environment biology in the cultural scene of existence in Cyberculture, in sensorimotor experiences in ubiquitous computing, differs from the connections and evasions of virtual environments for the mixed bioconnected spaces.

For these reflections, the James-Lange theories (the actions perceive the emotions and the brain interprets them), Cannon-Bard (emotion is felt first and then follows the cognitive actions, the thalamus and amygdala plays a central role, interpreting an emotional situation and, simultaneously, triggering the sending of signals to the Autonomic Nervous System and to the cerebral cortex, which interprets the situation cognitively) and Shachter-Singer (contributes with differences in emotion and self-perception), are extremely important for the 'Physiology of Emotions' in the aspect of a Biocybrid Ecology, of an emotion in a dynamic state of physical events, cognitive, and cyber data with the use of ECG, EMG, Galvanic Skin Resistance – GSR and NTC thermistor for creative, artistic purposes in human edges for expansion interfaces and perceptual and affective supplementation.

Environments and smart objects, augmented reality, ubiquitous computing, pervasive and tangible, make it possible to understand the body experiences in human-computer interaction, of emotions, cognition and perception through the body, physiology and behavior.

We give voice to human free will, by monitoring and detection of biological motion signals produced as a result of conscious choice or not, measured by technology. For this interaction, the LART Research Group adds the research of physicians, therapists, computer programmers and engineers with the

aim of detecting emotional expression, turning it into sounds and images projected on the environment, in a process called Data Visualization in which we contribute to the propose of the New Abstraction construction.

Featuring biosensors, one can detect tension and intentional movements of any person during an action, in a daily performance from or even in rituals that transcend one's own body, as part of a complex ecology of the cosmos.

PERFORMING STRUCTURE: FINE ART AS A PROTOTYPE FOR PARTICIPATION

Karin Hansson, Love Ekenberg, Johanna Gustafsson Fürst & Thomas Liljenberg

The art project *Performing Structure* (www.performingstructure.se) deals with the performance of organizational systems like democracy in a place structured by globalization. An art exhibition in the public space is employed as a way to better understand the conditions for democratic participation. In this work-in-progress, artists work in relation to research regarding e-democracy using the concept of art as a method to explore the context.

1. Introduction

In a recent overview of the research on e-participation, Macintosh, Coleman and Schneeberger [1] show that a more informed discussion regarding the importance of form and structure in democracy is needed in the technological development in the field. As, e.g., Sæbø, Rose, and Skiftenesflak [2] point out; current research on e-participation lacks innovation in the sense that most software is adaptations of existing technologies. Furthermore, the Internet is treated as a distinct artifact and technological solutions are mostly taken for granted. These approaches have seldom been successful regarding broad and representative citizen involvement, and in particular not in more socially complex areas. Moreover, Dahlberg [3] notes that a belief in the ability of technology to shape a neutral place for deliberative discussions is omnipresent in the discourse on Internet and democracy.

We are skeptical against a technology strongly influenced by a liberal notion of democracy as an egalitarian sphere for reasoning, rather than, e.g., a Foucauldian notion of hegemonic discourse shaped by power relations. The question then arises whether there are other complementary approaches to the field. Our approach is more along the line with Nowotny, Scott, and Gibbons [4] suggesting that socially embedded research could give way to more robust forms of knowledge production.

Therefore, we have recently started an art and research project exploring how an unconditional conversation about the common and socially shared space can take place in practice. In contrast to a technology driven approach, the argument is that art projects can be used as forms for both investigating and creating multimodal mediated participation. Furthermore, thematic art projects can be used as a way of prototyping for participatory democracy. Artists' actions, installations and role-playing create a direct

confrontation and interaction with a specific place and its inhabitants to explore the dynamic relationships that constitute its context. The notion of art creates a certain focus and expectation of seeing something beyond the everyday perception. We would like to see art as what Metzger [5] calls a “democratic technology” – an informal context that provides an unconditional opportunity to try different positions and opinions.

Since the participatory turn in the 1960’s, art that more directly includes the audience in the performance or the process has been thoroughly investigated. [6-7] Today, participation as an aesthetic component is common in the nomadic context of contemporary art. However, we think that too often, the critical potential in participatory art is reduced to symbolic gestures. We want to overcome this by situating a participatory art project in a local context and connect it with research on e-democracy, and thereby create a possibility for the art project to inform the research and vice versa. The conceptual starting point for Performing Structure is the recognition of the need to examine the norms and beliefs forming the basis of the structures and communication patterns that current technologies co-create. We are interested in the “doing” of democracy within science, and what the bases for democracy looks like. The focus is on the daily conversations in small and large groups and the mechanisms that shape these conversations.

2. The concepts of art as techniques

In participatory design, a multitude of art genres are used as a way of involving users in the process, such as probes, scenarios and role-playing. Here we won’t emphasize any particular artistic genre; instead we use different concepts of art as a way of exploring the conditions for a participatory democracy grounded in a particular context. Our techniques for exploring different perspectives on e-democracy include:

1. Subjectivity – to compare the site with other global nodes through artists’ personal experiences.
2. Conflict – to emphasize diversity and conflict rather than consensus.
3. Pain – to use the artwork as a memory-work, a technique for understanding underlying conflicts and detecting norms and behaviors.

2.1 A SUBJECTIVE COMPARISON BETWEEN KISTA-RINKEBY AND OTHER GLOBAL NODES IN PROCESSES OF RESTRUCTURING

The notion of subjectivity is strong in the avant-garde concept of art. We can reach a contextual understanding beyond statistic generalizations by departing from the individual artist’s subjective understanding of a certain situation. We situate the art project at Kista-Rinkeby, which is the home location for the e-democracy researchers. This is one of Stockholm’s more expansive suburbs, and a central location for global companies primarily in the information industry, and both Stockholm University and the Royal Institute of Technology in Stockholm have chosen to place parts of their operations here. It is also home for programs, such as the government-funded Spider (The Swedish Program for ICT in Developing Regions) which, among other things “exports” e-democracy to developing countries. Kista-Rinkeby is characterized by extreme local segregation, and those living there are not generally the same ones working there. The unemployment rate among the local residents is high as well as the proportion of immigrants. The place illustrates the new divisions created by globalization, where diverse socio-economic worlds become wrapped up in each other and where the state’s ability to balance differences has declined.

Here, technology has not decreased but increased disparities as the importance of social and cultural capital has increased in the networked economy in general. The latter is not unique to Kista–Rinkeby and in order to compare the site with other global nodes through artists' personal experiences, we invite artist from different peripheral nodes heavily restructured by the global system. One participating group is The Khoj International Artists' Association in Delhi, an arts organization where artists work in dialogue with the space at the intersection between art, society and urban development. The Moldavian artist Stefan Rusu uses art as a way to talk about social and political phenomena. He is also the leader of KSAK Center for Contemporary Art in Chisinau, Moldova, and has developed art projects throughout Europe, the Middle East and Asia, focusing on processes and changes in post-socialist societies. The Lithuanian artists Nomedas & Gediminas Urbonas also explore post-Soviet notions of changing national identity, and the conflicts and contradictions caused by the new economic and political conditions. They started JUTEMPUS interdisciplinary program for art in Vilnius, and VOICE, an online publication on media culture. In Kista-Rinkeby these artists will work in close relation to local Swedish artists and local organizations.

2.2 CONFLICT AND DIVERSITY AS A TOOL

Unsurprisingly, and as various social media has demonstrated, communication technology, is not necessarily alienating. It can instead support previously fragmented groups to keep together and provide the means for new communities with a shared interest to form and interact. Technically, it seems to be easier to lump together similarities rather than differences, and to design services that offer us new products and friends based on our previous choices. The technology thus niches us, shatters us, and makes the common areas of understanding lesser and easier to avoid. It is difficult to get along with “the other.” But in order to develop an understanding of the common it is not enough to talk only to people who think and act like us. A technique that is not based on combining equals but different varieties appears here as a discursive democratic utopia. In the choice of artists, we have therefore tried to see beyond our own aesthetic practices while creating a heterogeneous group of artists. By bringing together artists with different experiences and modes of expression, we are promoting a situation of conflict where the individual artists' subject positions are questioned.

Conflict is also a recurrent theme in art, where the individual artist is supposed to be in conflict with the collective system. An avant-garde artist breaks with the norms and differentiates himself from ordinary men and previous art. Standard in these settings is that an artist's role is created through a differentiation process, where an outsider is opposed to the norm; Avant-garde in contrast to the conventional; painting in contrast to performance, and so on. We take another direction in this project and depart from our different perspectives; deconstructing the norms that create a difference while looking for a common denominator. To avoid locking into just one perspective, ten invited artists and artists groups approach the subject from a multitude of angles such as community art, urban installation art and activist art. The artists are using locative and interactive media, as well as more traditional artistic techniques. The particular art genre is not important here; a common denominator is that the artists work with situation-specific emancipatory art projects that in various ways relate to the physical and mediated public sphere. Therefore, we do not emphasize a particular artistic method, but rather the *actual meeting* between the artists and the procedures for dealing with differences. Using the thematic exhibition as a framework, different artistic perspectives create a triangulation of methods where a more diverse and complex picture of the situation can emerge.

2.3 THE COLLABORATIVE DEVELOPMENT OF THE EXHIBITION AS A MEMORY-WORK

Through the joint development of a theme, the group exhibition works as a special form of knowledge building. This has similarities with Frigga Haug and others' method of *memory-work*, [7] i.e., a qualitative method that uses the memories of a group of researchers to investigate norms and social structures. This use of personal experience as a tool for academic analysis is based on Husserl's systematic attempt to examine the subjective unconscious where he argues that we can reach a general understanding of a phenomenon by understanding the individual's experiences. [8] The idea behind the memory-work method is that memories often derive from situations where we have experienced a taboo or a cultural constraint that caused a conflict. But to get to the underlying experience that caused the memory, one must see through cultural norms and behavioral patterns. The memory-work method is specifically intended to reach to the underlying experience. To achieve this, one begins by describing the individual's own conscious memories. The collective analysis of each memory is then intended to identify the underlying conflicts and to detect the cultural norms and behaviors involved, i.e., the very reason for why the memory has become a memory.

In the project, we consider the similarities between the memory work approach and the thematic group exhibition and develop our own method of collective knowledge production. Within the framework of the arts organization *Association for Temporary Art [a: t]* Åsa Andersson Broms, Nils Claesson and Karin Hansson previously carried out a series of thematic art projects and exhibitions related to the information society and the changing conditions for democracy: *Best before - on the Information Society*, Tensta Konsthall (1999), *The Art of Organizing*, Gallery Enkehuset (2000), *Money - a commentary on the new economy and Public Opinion* at the Kulturhuset in Stockholm (2001, 2002). Central for the work is the collaboration between the artists and the ambition to create something beyond the multiplication of the single parts. This way of working with a thematic art exhibition has many similarities with the qualitative research method of memory-work. The artist most often departs from his or her subjective experience of the chosen theme and focuses on the elements that he/she thinks are interesting. What is interesting most often means some form of unresolved conflict that chafe at the individual or societal level. The motivation for making art is to a great extent about the need to express a subjective experience/interest on a structural level where others can read it. The collective process in a group exhibition, where artists share their ideas and reflections with each other, works at its best as a collective memory-work where the discussion of ideas creates an understanding of underlying conflicts and detects the inclusion of norms and behaviors; the very reason that the art has become an art work.

The planned exhibition is developed in the group of artist through a collective memory-work.

3. Artists and art projects in process

Most important in the project is the invited artists' personal engagement in the theme and interest in a joint development of the underlying ideas. To reach beyond symbolic gestures of community the privileges of the artist as well as researcher are examined and questioned.

To mention some of the ongoing and planned art works within the project: A project that already takes place in the Kista-Rinkeby area is Thomas Liljenbergs' *Kista Art City*, where a joint art project creates a starting point for a wider discussion about community participation and notions of belonging among the citizens of Kista. Shiva Anoushirvani's work takes place at the intersection between art, activism and performance. As part of the artist group RAR: Rapid Art Response she develops the project *Dear Citizenin*

collaboration with Husby Arthall. Here acts of democracy are taught through performance and role-playing.

One aspect of the theme is how technology can (or cannot) demonstrate and change social structures, and thus operate in an emancipatory direction and to broaden democratic participation. The artist Johanna Gustafsson Fürst, together with Kista Theatre explores communication technology applications related to a specific location. In the project *I'm Your Body* they use mobile GPS technology to create a parallel public place within Kista-Rinkeby.

Mass-distributed collaborative processes such as crowd-sourcing and open source are also an aspect of the technology that is interesting from a democratic participatory perspective. This is the field of Karin Hansson's work, *Actory*, a collaborative groupware based on the sociology of the art world, developed together with students at the Royal Institute of Art in Stockholm and researchers at Stockholm University.

4. Art as Prototypes for Participation

To conclude, this project contributes to the discussion about artistic research by showing how situation-specific art can be viewed as a qualitative method for highlighting and exploring discursive practices. Through a triangulation of different artistic perspectives the themed and collectively generated art exhibition creates a diverse and complex picture of notions such as participation and democracy. The artistic work is an iterative process where concrete images, scenarios and situations create a direct communication with the site. We want to see the project as a construction of prototypes for alternative societies as well as a laboratory for participation. Following a rich tradition of participatory art, we emphasize the artists' capacity to listen, interact and respond. Art is not something that comes in from above or outside. Instead it should be grounded in the activities at the site, creating meaning beyond the context of contemporary art.

An important practical input into the project, is achieved through the activities undertaken by local organizations such as Kista Residential College for Adult Education, Husby Association for Arts & Crafts, Husby Yard and Rinkeby People's House. The artists within the project are working in direct relation to existing activities. During the spring and summer of 2012, a number of art projects will be carried out in the public and semi-public space in Kista-Rinkeby.

CAN DIGITAL OBJECTS BEHAVE WELL (IF WE LET THEM)?

Dew Harrison

The *Shift-Life* Installation. Dew Harrison.

Within my practice I have an interest in how computer technology can augment our thinking and elucidate deeper understandings of issues and positions within the art field (see Tamblyn). In particular I have been investigating the work and ideas of Marcel Duchamp as the instigator of Conceptual Art practice and how new technologies are best suited to enable a re-articulation of them (see Blais, Gere, Manovich, Rush, Shanken, and Harrison 1999). Early works transposed his Large Glass across the internet, and inter-related Duchampian images with his notes (Duchamp 1934, 1966) into discreet offline systems. These pieces were made using hypermedia software as this enables the linking of multimedia items by semantic association rather than by indexing or alphabetic ordering (Harrison 1997). This connectivity by semantic association is paralleled in Conceptual Art where ideas are semantically linked by the artist into one concept – often presented as a visual statement, an object.

As technology advances, the interactive interfaces, which are signatures of digital artwork, can become less visible and taxing to the viewer. My work reflects this in its move towards engaging participants through intuitive interfaces with less machine-like ways of access. From mouse, keyboard and screen - to sensors, projections in physical spaces and material objects. In order to achieve more organic means of semantic association, I am now incorporating Artificial Intelligent (AI) behaviours into my Duchampian art systems to animate data objects. Recent works have bestowed the digitized Duchampian items with flocking behaviours in order to interrelate them into families of meaning, the result being more akin to a

projected animated painting in that they are not interactive and require contemplation in considering their shifting positions.

'Flocking' is more usually associated with the collective animal behaviours exhibited by many living beings such as birds, fish, bacteria and insects, but can be more largely understood as the motion of a large number of self-propelled entities (see Reynolds). It is considered an 'emergent' behaviour arising from simple rules that are followed by individuals and does not involve any central coordination. Flocking behaviours can be applied to animal-like and non-animal-like entities and the first experiments with Duchampian items are simple rather than complex, using 'Flash' to animate them. The intent is to show the criticality of oscillation required in determining the Bride/Bachelor families and shifting relationships within the Duchampian universe of objects. These are image only objects at present but when texts are added they might provide a meta-language of semantic understanding concerning Duchampian ideas, with the object/behaviour patterns lying underneath and of less interest to the viewer. They could illustrate the flux and flow of his ideas and if emergent behaviours arise may enable new discourses within the system.

It is these Duchampian experiments which have led to the hands-on installation, 'Shift-Life', by directly influencing the approach to an exploration of Darwin's 'big idea'. Instead of Duchampian objects, AI behaviours were attached to a virtual world of animated objects featured as creatures and plants that adapt to Darwinian principles for survival. These 'families' were grouped by their form and colour, and it is the changes in these identifiers that are of interest when observed by viewers who can cause physical upheavals in their world, to which the artificial families of life-forms then have to respond. The *Shift-Life* project entailed a fantasy biological life-form, 'bugs-in-a-box', existing in conditions analogous to Darwinian evolution. Interfering with the stability of their ecosystem was done through real world actions directly affecting the virtual one. The work relied heavily on the 'animal intelligences' programmed in to display accelerated Darwinian principles by allowing them survival strategies (Ch'ng).

In attempting to both respond to the idea of a young Darwin and to elucidate his adult thinking in a holistic hands-on way, the bug-like creatures in the box reflected his childhood interest in natural life-forms by taking the form of beetle-like jelly sweets and allsorts. These virtual creatures existed in a nutritional (trophic) relationship of prey/predator and vegetation with both rooted (sessile) and free ranging (vagile) organisms. They were short-lived (60 seconds minimum and 150 seconds maximum) graphically represented as 2D and brightly coloured cartoon animals. Each plant and animal type had distinct behaviours, for instance the herbivores were big, slow and lumbering, they reproduced by laying jelly bean-like eggs and could survive the toxic plants if they didn't eat too many of them. The Carnivores were quick with a scuttling gait, they could only see straight ahead and reproduced by cloning, they would die if they ate a herbivore who in turn had nibbled on a toxic plant.

In order to allow people to interact with the Darwinian 'sweet' bugs the virtual world was projected down into a real wooden box arrayed with sensors. These sensors relayed data from the visitors actions directly to the virtual ecosystem where the animals and plants would react accordingly and in real-time. As someone used a watering can to pour liquid into the box, for instance, the planet humidity altered and some plants die back, this meant less food for the herbivore green jelly sweet bugs, and consequently less bugs to eat for the pink carnivores. Switching a lamp on would dry out the atmosphere and enable the plants to grow again, however too much 'sun' might be detrimental to the point of scorching the planet surface dry and wiping out the carnivores entirely with no water and no trees for protection. The carnivores could become extinct due to their reproduction method of cloning, unlike the egg laying

herbivores. Pouring vinegar (poison) from a watering can would 'feed' the red bushes, toxic to all the creatures, but this could be remedied by pouring baking soda liquid (plant food) and restoring the plant balance, the herbivores' main food source. Banging on the edge of the box with a toy hammer caused earthquakes, which sent the carnivores into panic mode and they would spin around and run for cover under the trees. (Harrison, Ch'ng et al)

The low-tech approach to a hi-tech installation encouraged active participation but also a state of contemplation and reflection in passively observing other people's actions and watching the subsequent life-form changes taking place. The jelly bug world was set at a self-sustainable and stable level without the intervention from human meddling and as such was visually mesmerising, it was essentially a sugar-coated version of 'nature red in tooth and claw'. Through listening to the participants' conversations it was evident that there was room for deep thought, where the virtual world could be understood as an analogy for human activity and its effect on global climate change within our own real world. The animal behaviours, although quite complex with around 15,000 lines of code, were still fairly basic, but the question remains whether if given more sophisticated behaviours and left longer between the human interventions, would emergent behaviours become apparent within the social groupings of the creatures as they adapt to survive.

Both the Duchamp and Shift-Life projects await their next stages, visitors may need to view passively, observe and contemplate following any interaction with these 'live' systems, as unpredictable behaviours arise from digital objects.

IDOLS AND ART: THE COGNITIVE FETISH

WILLIAM HART

Drawing upon theories of embodied cognition and the extended mind and the writings of maverick psychologist Julian Jaynes, this paper speculates on the function and roles of anthropomorphism and idolatry in our relationship with technology.

Objects and Anthropomorphism

In her abstract for this panel Nancy Mauro Flude concludes with the question:

“Anthropomorphism continually haunts us, and our machines – have we always been and will we fundamentally remain idolaters?”

From religion to Barbie dolls and the family pet, anthropomorphism is fundamental to the way that humans relate to the world and objects around us. We make god in our own image, and he generally shares our political beliefs and social prejudices. With dolls we can explore our social fears, frustrations and interactions with others, safe from the emotional holocaust of the playground. If we didn't anthropomorphise our pets, we wouldn't empathise with them, and they would cease to be pets.

It is through anthropomorphism that we relate to entities that we see as separate to ourselves, it is a prerequisite for empathy. However a cursory consideration for the history of human interaction with our fellow creatures makes it quite clear we are capable of being selective in our anthropomorphism.

But is it useful to anthropomorphise my toaster and worry that it may be getting bored from cooking too much toast, or fret that my bicycle is feeling rejected because I haven't taken it for a ride recently. Or that my laptop is impatient because of the time I wasted in looking at pictures of robots while avoiding writing this talk.

So the question is, with what and when should we anthropomorphise? To gain some insight into this I'd like to mash up two theories that lie outside the mainstream.

The hypothesis of the Extended Mind

The first is the hypothesis of the Extended Mind, first put forward by philosophers Andy Clark and David Chalmers in 1999. [1] Clark and Chalmers argue that cognition is not confined to the brain or even the body. As humans we have evolved to co-opt aspects of our environment to augment our thought processes. For instance we can count larger numbers using our fingers, codify abstract information using dirt and a stick, or enhance memory by writing things down on a notepad. Clark and Chalmers argue that by learning to use and rely on these external objects they become equivalent to the internal processes they augment or replace.

Under this view, my laptop is not something that I anthropomorphise, it is actually a part of me, it augments my ability to write, to remember, to visualise and to know. I don't ascribe feelings to it; in the

same way I don't ascribe feelings to a limb or organ. Before I can anthropomorphise a technological other, it has to be an automaton – an independent machine entity.

Julian Jaynes and the ability to Anthropomorphise

The second and somewhat more radical theory I'd like to discuss is by maverick 20C century psychologist Julian Jaynes. Jaynes in his 1977 book "The origin of consciousness in the break down of the bicameral mind" proposes that the structure and organisation of the human mind has continued to evolve since Palaeolithic times. [2] Our modern conscious self-awareness, the introspecting 'I', emerged only 2000 years ago under the pressures of increasingly large and complex societies punctuated by natural disasters and war.

Before then Jaynes believed that our minds were bicameral in organisation, that the two hemispheres operated independently, the left-brain dealing with the routine details of the present. The right brain would communicate with the left through auditory hallucinations in the form of commands apparently from authority figures. At first the authoritative voices were those of the chief or king, and when the chief died his would continue to be heard, and became the first gods. In their left-brain state the people were caught in the moment; lacking introspection they were capable only of dealing with normal routine. When faced with stressful situations or problems outside the norm the voices from the right would provide advice or command a course of action. Jaynes paints a picture of a peaceful ordered society where everybody knew their place, where people literally walked and talked with their personal gods.

It is impossible to do justice to Jayne's theory in a few sentences, and perhaps it sounds a bit like something from the pen of L Ron Hubbard or Eric Von Daniken, but Jaynes's scholarship is impressive and he uses his theory to describe one of the most intriguing explanations for the development of religion that follows the gradual breakdown of the bicameral mind. As the individual sense of self-awareness grew, the hallucinated voices began to fade. The insecurity and loss of certainty that this created drove humans to find ways to try and recapture the direction and wisdom of the gods, and so developed increasingly complex and desperate ways to recapture this connection. Idols, prophets, oracles, seers, prayer, divination, auguries, poetry and art were all at different times used as ways to invoke the lost voices.

For instance the idols of the early first millennium BCE had large exaggerated eyes which command attention, and Jaynes hypothesised that the large eyes of the idols aided the people in entering states where they could again hear the auditory hallucinations. It is hard not to wonder if we still see vestiges of this in the large eyes of anime characters, or in the power of television to captivate us.

Neuroscience and thinking through objects

The insight and knowledge gained from neuroscience over the past twenty years tends to support some of Jayne's ideas. Cognition in the view of Neuroscientist Antonio Damasio involves emotion and physical sensation as much as it does logic or mental reasoning. [3] We say that cognition is embodied, that we use our body and intuition as much as reason to make sense of the world. We all know as artists, that you don't make art through normal verbal consciousness, and while we no longer wait to be possessed by the Muses, we do make use of non-conscious understanding and intuition. A part of the art making process for many is an almost trance like engagement with materials as we think through our work.

Art historian Barbara Stafford talks about the power of art to construct analogy and develops a theory of art where artefacts are cognitive objects that communicate through analogical thinking. [4] In a similar way that Clark describes the way we use objects in our environment to extend our mental capacity, it is hard not to conjecture that when we engage with an artwork we participate in an act of communion or communication with it, it becomes part of our thoughts. In this view the idols of the ancient world are cognitive aids that helped them to enter a mental state where the right side of the brain could direct and advise the 'everyday' left via aural hallucinations.

Idolatry is a contemptuous term, it implies an unreasoning worship, an unfounded abasement before inanimate objects – and so it must have seemed to those who no longer entered the trance and were cut off from the voices. Did the Idolaters anthropomorphise their idols? Their relationship would have been too literal for the metaphorical anthropomorphism that later developed.

Conclusions

In pondering the perspectives that the theories of Clark and Jaynes provide, I've come to the conclusion that we need a different category to describe our relationship with our digital artefacts. They are not inanimate objects, yet neither are they in their current form alive and worthy of empathy. They are the new idols, and we engage in idolatry that extends from the naive to the sophisticated.

At the naive extreme we may anthropomorphise these artefacts and ascribe authority to what they tell us. For example television is the ultimate Idol for the naive, it places us in a trance like state of passivity as it informs and commands.

At the other extreme they are thinking tools, augmentations that we have co-opted and incorporated into our cognitive frameworks, they become part of what we are, not some other. We think with these artefacts and not so much about them.

As technological humans we are idolaters, but that doesn't mean that idolatry is unquestioning worship from those in thrall to the idols, it could be the sign of a fruitful cognitive engagement that can extend our thinking and understanding of the world to places and states that haven't been possible before.

THE NEURO-LOGIC OF SOFTWARE ART

WILLIAM HART

This paper considers programming in relation to the International linguistics of Roy Harris and the Expanded Mind hypothesis of Andy Clark. It is argued that the use of the term 'language' when referring to programming is a category error that has implications for the practice of Software Art. Developing a practice of Software Art requires an open-ended and heterogeneous approach to coding involving a range of cognitive states.

"The computer is a kind of wishful self-portrait... a compendium of abilities we have as humans aspired to but are not very gifted at. We need a much clearer understanding of this complex relationship. Without this understanding we will be unable to find an appropriate partnership with our creations." [1]

Introduction

Over ten years ago I undertook my first software art project entitled The Writing Machine. At the time it had been some years since I had engaged in a serious programming project, and this was the first time aside from some scripting that I had undertaken programming with the object of an 'art' outcome, but I had had considerable previous experience in large and small experimental software projects. An initial prototype written in C for the artwork that had the essential behaviours was produced quite quickly, but then the project stalled - and failed to reach an aesthetic resolution. It was as though the material of the project became heavy, brittle, and eventually unworkable. I've since spent a considerable amount of time considering why. It would be easy to say that this failure was due to a poor software engineering methodology, but while making an artwork sometimes generates engineering problems, engineering does not describe the methodologies that an artist uses. Artworks rarely address a problem or provide functionality, in the way that engineering processes do. This has led me to explore the qualities of different programming languages, looking at processes for rapid development and flexible refinement, but that also allow for diversity of expression.

As part of this exploration I have looked closely at the relationship between humans and machines, between the formal constructs of programming and human language, and ask, what is relationship we have with the machine and what are the constraints on using it as a creative medium. I contend, that in considering programming as an expressive medium it is necessary to consider the types of cognitive states artists engage in and examine the concept of language as it relates to the domains of human discourse and computer programming. In contemporary times we are very comfortable with computing devices, with the idea that these devices occupy an intimate part of our lives, and the mainstream view is developing that it is valid for artists to be involved with, programming, hacking, tinkering - making and unmaking this machinery, as part of a creative practice that results in an experience called art.

The Artist Programmer

There appears to be a consensus that the artist engaged with programming as a creative medium should, as their skills develop, move from conceptually simpler to more rigorous (in a software engineering sense) programming environments. For instance from a visual programming with node based

metaphors such as Max/MSP or Quartz Composer, through customised IDE's (Integrated Development Environment) with scaffolded programming support such as Processing graduating to C++ using API's (Application Programming Interface) such as OpenFrameworks or Cinder. A common rationale is that C++ applications are faster, more extensible, capable of increased complexity and have greater robustness. In this paper I argue that software art is not software engineering, that a different approach is required, to achieve the flexibility, richness and ease of comprehension that expressive software art requires.

It isn't necessary to look too far back beyond the past decade to find a general unease with the possibility of the coexistence of technical proficiency in computer technology and creative expression. Current histories of software art often claim a heritage from the conceptual art movement of the 1960s, but few are enthusiastic in claiming a lineage from the Computer Art movement of the 60s, 70s and 80s, a movement which many would still claim failed to produce art worthy of consideration. [2]

The Program as Artefact

Perhaps this is partially because the concept of what art is has changed since these times. We have seen a move from the emphasis upon the art object to an emphasis upon relation or process. I remember reading an article and looking at images produced by Harold Cohen's drawing software AARON in the early 1980s and being disturbed and slightly enraged. Partially my discomfort was due to the article (and Cohen) ascribing intelligence and creativity to the software - whereas all I could see was software that produced pictures with recognisable forms, but that were always the somehow the same. Years later as I pondered the problems of writing software and creativity I began to realise that while it is true to say that AARON failed to produce engaging art objects or to display 'creativity'; it is the project in its entirety and the knowledge it represents which is the artwork.

Throughout the history of artists' engagement with computers, there has been recognition that something 'new' or novel is happening, a new medium, a novel approach to making and disseminating art - a different mode of expression than had been seen before.

The Computer Art of the 1970s and 80s suffered the disregard of the mainstream art establishment as much because of its inability to demonstrate the value of this 'newness' in ways other than novelty, and because of its association with the dehumanising program of hard AI and the military industrial complex. With the advent of the personal computer revolution and development of desktop publishing and image editing, the computer demonstrated an ability to simulate processes of traditional media (at first quite crudely and was met with a degree of scepticism by practitioners skilled in traditional analogue media). It was this ability to firstly approximate through simulation the processes of traditional media and then such as with the case of video quite quickly surpass the processes of analogue media that led to the general acceptance of the computer as a tool for artists - not its capacity for novelty.

The novelty of Computer Art?

What is this new thing though? Dominic Lopes in "A philosophy of computer art" makes a distinction between Computer Art and Digital Art, the latter he defines as art which rely upon the ability of the computer to encode and manipulate data, and is not a new art form - a digital image is still an image, digital music is still a kind of music. [3] Computer Art he defines as art works, which when run on a computer have a quality of interactivity. So for Lopes the 'new' thing is the quality of being interactive. Interactivity

as the prerequisite of difference alone seems to hark back to the new media of the 1990s as a way of distinguishing the 'newness' of art made with the computer. For the purposes of this paper I would like to instead explore this idea of 'newness' as being a cognitive loop between artist and computer, rather than as a dialogue the artist has with the computer or something that the artist expresses through the computer. Digital Art is now the mainstream, it is ubiquitous and its tools of production are invisible. There are numerous social and political problems with the solely media centric approach of digital art, but they are not what I want to address here. Instead I want to look more closely at the processes and context of the engagement between human and computer we call programming, and how it could result in a thing we call art, particularly where the artist and programmer are the same person.

I would assert that this activity we call programming is more than a utilitarian or instrumental one, that the requirements for a programming environment are different for an art activity than for an engineering one. An art project may have non-specific goals and will certainly have different criteria for determining points of completion. Art historian Barbara Stafford places analogy at the heart of the art experience, in making, as much as receiving art we are engaging in 'analogical thinking', satisfying art experiences generally engage through either an unstable and shifting meanings, or in a richly nuanced web of correspondences. [4]

Analogy, Language and Programming

Analogy / Metaphor is very powerful, it is arguably the essence of cognitive process, it gives the power to create and manipulate complex abstractions. Where analogy is in constant use it becomes invisible, and we cease to be aware of the underlying assumptions. We all know that programming languages are not the same as human 'natural' languages, but implicit in almost all theoretical discussion is the idea that on some level that it is. We talk about codes, and encoding interchangeably between analogue and digital, between organic and machine systems. But what if there is no correspondence between language and programming dialects.

There have been a long history of technological metaphors used to describe aspects of human cognition; many have become deeply embedded in consensual language and understandings. For instance the telegraph and telephone exchange were common metaphors for brain function in the early 20th Century, the photographic image as an analogue for visual perception is still a widely held naive conception. The computer as an analogue for the brain, and software for the mind, has been widely used for the past 50 years, although it is also a metaphor that is violently rejected by many. Sometimes terminologies that have been analogised from one discipline of thought to another create a further implicit confusion. Take for instance the term 'ontology' it has distinct (but analogous) meanings, whether you are discussing philosophy, cognitive science or computing. In philosophy ontology is concerned with the existence and relationships of categories of being, whereas in information science ontology is a representation of a domain of knowledge based on a formal description of concepts and relationships, taxonomy and properties. So in one discipline ontology is metaphysical; open to interpretation and in the other it is formal; precise and closed. When we discuss ontologies in terms of art and programming there is naturally a bleed from one conception to the other, a confusion between metaphysical and material modes of expression.

In the early 1950s, at a similar time to the development of the first computer programming languages such as FORTRAN and LISP, Noam Chomsky developed his linguistic theory of Universal Grammar, that is, there is a universal structure of grammar hardwired into the brain, with the implication that all human languages share a common set of fundamental rules, a formal description. Programming languages are 'Turing Complete', that is formally a logical construction in one language can also be represented in another, even though the code and logical structures of the programming languages may be quite different. Chomsky also constructed a hierarchy of formal languages, with Turing complete formal languages at the lowest level, and several levels of more complex formal grammars above that. The implications from Chomsky's theories were clear; all human languages were syntactically equivalent to each other, as were all programming languages, with programming languages being a simplified version of the languages of humans. So the idea that we think and communicate through code entered the public consciousness and was firmly embedded through the use of terms like programming 'language'.

To understand how prevalent was this assumption it is instructive to look at the history of machine language translation, the optimism in the field in the 1950s repeatedly asserted that machine translation was a problem that would be solved in the near future. [5]

Cognitive Psychologist and author Steven Pinker currently champions the idea of a Universal Human grammar, and popularised Chomsky's theories widely in his 1994 book "The Language Instinct." [6] But the theories and debates around the acquisition and representation of language in the mind are complex and vigorous, and there are a number of opposing theories to this idea that language is in some way hardwired into the brain.

BUT IF LANGUAGE IS NOT A CODE...

One of the theories that Chomsky's Universal Grammar displaced was the Sapir-Whorf hypothesis or linguistic relativity. The hypothesis, briefly stated, is that the language you speak with determines what and how you think; the form and structure of different languages can be unique, which lead to different conceptions and understanding of the world. In recent years the credibility of the Sapir-Whorf hypothesis has been revived by the work of Cognitive Psychologist Lera Boroditsky. Boroditsky looks at indigenous peoples and their languages, and how constructs available in the language they use affect the way they interact with each other and their environment. For instance she describes how some languages such as Kuuk Thaayorre spoken by indigenous people in Northern Australia, do not have concepts for relative spatial location such as left and right, but instead always use absolute directions, for instance they would not say you are in front of me, they would say you are to the north. Consequently people who natively speak this language always know where they are orientated, a characteristic not shared by people who use languages with concepts of relative location. [7]

AND COMMUNICATION IS MORE THAN LANGUAGE...

Integrational Linguistics is a branch of linguistics that was developed by Oxford scholar Roy Harris during the 1980s. Harris criticises what he denotes as the "language myth" that dominates Western linguistics. Integrational Linguistics rejects several implicit assumptions in conventional linguistics, particularly the idea of communication occurring through a system of signs that have a meaning and existence separate from the context in which the communication is occurring, or that human communication occurs through a mechanistic process of mental formulation – the idea that meaning is encoded into speech

where is it transmitted to the listener who decodes it into a mental representation. Consider an example of integrated communication, if I am carrying a load of heavy boxes, and I ask you for help, you assess my difficulty and take a box from me, to which I respond 'thanks'. We have engaged in an integrated act of communication involving spoken word, gesture and physical action. For the Integrationist, communication is always a collaborative creative act steeped in the context of the participants, it relies as much on physical acts or responses as it does on verbal or signs. [8]

Cyborgs: thinking through objects

Embodied cognition is the theory that a body is essential for thought, that physicality, sensation and emotion are essential components of mind. Philosopher Andy Clark takes this a step further with the theory of the Extended Mind. In the extended mind hypothesis the mind can extend beyond the brain and body into the external environment through objects such as notebooks as part of the cognitive process. In the original paper Clark and Chalmers argued that if a person, Otto, has Alzheimer's disease and routinely relies on a notebook to act as his memory, the notebook is not merely an instrument, but under Clark's parity principle is cognitively equivalent to a normally functioning memory. As Otto's cognition extends to his notebook, it is effectively his memory. Clark contends that humans are naturally cyborgs, creatures who routinely cognitively co-opt artefacts. [9] Interviewed on Australian radio Clark relates a story about how once when he lost his laptop it was the cyborg equivalent of having a stroke, which left him shaken, dazed and confused, its impact was worse than when he had an actual mild stroke several years later. Most people who have lost a laptop and through it engage with the world of ideas will relate to Clark's anecdote.

After pondering the idea of the dynamic and creative process of communication that Integrational Linguistics describes, which relies little on the transmission of coded signals but upon body, environment, history and context to develop understanding, or the way that the Extended Mind hypothesis argues that we use the environment around us, it is hard to continue to think of artworks as static objects, but as dynamic cognitive systems which draw us into a dialogue of analogy and sensation, or as Barbara Stafford describes them, "echo objects." [10]

Software art is interesting philosophically and cognitively not just because of its potential 'newness', but because it sits at such a distinct interface between formal logic and fuzzy expression.

Conclusions

When we engage in programming, although we use terms like 'language' and 'writing' we are not engaged in discourse with or through the computer, but are engaging in an act of cognition. This extended cognitive state involves a variety of different modes as the software develops through; inspiration, discovery and exploration, experimentation, play, construction, reflection, analysis and intuitive modelling. When engaging in a creative process through crafting software, it is not enough to just string a sequence of function calls together, or to solve a complex technical problem, or to demonstrate the capabilities of an algorithm. It is the engagement with the full spectrum of cognitive modes that leads to a resolved creative outcome.

Many of these cognitive modes are common to all forms of art practice, some like the one I have labelled discovery and exploration are more specific to software art. To move a project beyond its initial

inspiration may require lengthy exploration to find a way to proceed or a form to follow. Intuitive modelling or tweaking is unique to technical processes, as a program is developed there are often a large number of arbitrary variables that control behaviour and other qualities. Mathematicians refer to this as a parametric phase space, the multidimensional space describing the range of possible behaviours the program has. A key (and often very time consuming) aspect of the development of the program as an artwork is exploring and experimenting with different values and combinations of parameters. It is through this play that an intuitive sense of the shape and form of this phase space develops which leads to the final selection of values and consequent behaviours.

As an artist-programmer I advocate adopting hybrid approaches mixing languages with high levels of abstraction with low level high performance code based on the type of cognitive engagement being undertaken. I am not trying to engineer an application or create aesthetic code. I am struggling to enact a process of communication with the viewer.

SUSTAINABLE PRESERVATION PRACTICES AND THE RHIZOME ARTBASE

Nick Hasty

Founded in 1999, the Rhizome ArtBase is an online archive of new media art containing around 2508 art works, and growing. The ArtBase encompasses a vast range of projects by artists from all over the world that employ materials such as software, codes, websites, moving images, games and browsers to aesthetics and critical ends. The paper documents the past, present and future preservation practices of the Rhizome ArtBase.

As laid out in our mission statement, Rhizome supports “artists working at the furthest reaches of technological experimentation.” A major part of this mission is the preservation of works of art, through our online archive, the ArtBase. There are two fundamental threats to this preservation: diffusivity, and digital obsolescence. We will explore these risks respective to works by artists JODI and Golan Levin, as a basis for approaching solutions that may mitigate these risks.

INHERENT VICE & ARCHIVAL MATERIALS

Diffusivity is a term that refers to works whose content is not contained within one digital object. In some instances this can refer to works that reference external databases, or dynamic and real-time data sources but also refers to works that exist primarily as a series of actions over a variety of locations and platforms. [1] These works present a structural complexity that creates new problems for the archive. An early example of a static, non-diffuse work is Olia Lialina’s *My Boyfriend Came Home from the War* (1996). The piece consists entirely of HTML documents and GIF images contained in directory that could be easily duplicated and stored in the ArtBase. A work that is diffuse presents a structure that is diametrically opposed to objectification and ownership. *Globalmove.us*, by seminal net.art duo JODI, is a glitch website that implements HTML, Javascript, and the Google Maps API. Through the combination of the API and home-brew Javascript, the artists have created a website that negates user interaction, and creates frenetic, drawings using Google Maps interface elements. Here, the functionality of the art object entirely hinges on an external element - the Maps API. Sooner or later, JODI’s Javascript will be rendered ineffective as a result of further development of the Google Maps API. What steps might be taken in order to mitigate this?

The primary mission of the archive is to stabilize the unstable/external element (the Google Maps API). Here, a need emerges for institutions such as Rhizome to collaborate with private sector institutions such as Google. It is simply a reality that corporations and other third parties create and control much of the materials that are used by the artists we support. While it would be unthinkable for Rhizome to host an archived instance of the entirety of Google Maps, a truncated version including the functions and data called by JODI’s piece could be created. With this action taken, the API is no longer an external element and it’s fixity is ensured.

Next, we will explore the inherent vice of digital obsolescence as illustrated by *Floccus* by Golan Levin. Digital Obsolescence is perhaps the most pervasive threat to digital works. New media at its very core is built, and manifested with tools and technology that are interdependent – no element of software is autonomous. There is no artist or programmer who is not dependent on (or limited by) infrastructure built by other programmers. An artist who writes software, relies on running within a specific

(or at least a finite range of) operating system(s), and therefore on specific hardware. A recent case of obsolescence was illustrated by Golan Levin's *Floccus*. This piece created in 1999, has to date witnessed two generations of obsolescence. Levin originally created the piece using the C++ programming language and OpenGL (Open Graphics Library). It was then compiled as a Java applet capable of running either as a "stand alone" piece of software, or as an element embedded in a web page. In the intervening seven years after its creation in 1999, computer systems evolved and support for the applet began to disappear. In 2006, the artist found that the applet began to fail, and would no longer run on many contemporary systems. Levin remedied this by recreating the piece using Processing (a tool that emerged after the work's first iteration). This process also rendered an applet, which Levin embedded on a page of his website.

Floccus was once more rendered obsolete; until recently the web-based applet would not run, and visitors to Levin's site or the ArtBase would be presented with only a blank white box and error message. After investigating the issue, Levin found the problem to be that the applet was compiled to run on now obsolete 32 bit systems. Today, 64 bit systems are the predominant norm, and prior to its repair, the applet was likely unusable for the majority of visitors to his website. This particular case is a perfect example of the recurrent nature of obsolescence; once an obsolete art object is restored, it is only a matter of time before the solution is rendered obsolete. The most evident repercussion is the work of art no longer exists from the viewer's perspective. Without action, obsolescence creates an air of mythology – an inaccessible history. Levin's *Floccus* presents material gathering needs specific to compiled software. Unlike a web page's uncompiled markup language, readable by both machines and humans, once compiled source code forms a stand-alone applet or other form of software, accurate human analysis of the work is made impossible. Compiled applications do not allow for the ability to understand the artist's programming logic, structure, and style. In a restoration scenario, this information is integral. In the case of *Floccus*, there are five primary entities that must be gathered to form the archival package: the Processing source code, a font file that is used in the piece, the compiled Java applet, the compiled P3D Processing Applet, the original 1999 C++ source code, and the compiled software of the C++ version. With the description of the work, the images of its documentation, and analysis of the various formats of source code, there is ample information to inform accurate reinterpretation in a restoration scenario.

STRATEGIES AND METHODS OF RESTORATION

Beyond gathering of archival materials for the stabilization of works, there are three commonly acknowledged forms of restoration: emulation, migration, and reinterpretation. This section will explore these established methods within the context of the previously discussed works. Through this theoretical exploration, and the findings of the Variable Media Network's case studies, an analysis of how relevant these methods are to the ArtBase will be provided.

Emulation is the simulation of the architecture and behaviors of an old computer system, within a contemporary system. [2] For instance, if an art object will no longer run on contemporary operating systems, a piece of software may be written that emulates the environment of the work's original operating system. This strategy is efficient insofar that the emulation of one operating system creates a solution for accessing all works that originally ran on that system. Still, it is only a temporary solution – with time the emulator itself will become obsolete and unusable on contemporary computer systems. While case studies have shown that emulation is effective at producing an aesthetically authentic iteration of art objects, these studies have also shown that it is fact quite a in-depth process best suited for circumstances that justify a high level of investment in a short-term solution. [3]

Thus it follows that the prerequisite for restoration efforts is not simply for a work to function outside of its original format, but to a broad base of rapidly evolving web browsers and operating systems. Deprecation and obsolescence is a necessary evil for an evolving Internet. Yet, software efficiency and the politics of emergent web standards is a concern secondary to our goal of having the ability to properly support a chronological legacy of internet based culture and creativity. This establishes the need for a “museum quality browser” – one that runs on contemporary infrastructures and provides legacy support for archaic protocols and markup of the early days of Internet art. Rather than adopting a policy of deprecation, such a browser would be built on a development philosophy that is additive, providing native support for emergent standards and preserving support for the old. Building upon open-source frameworks such as WebKit, or Gecko would be ideal as they come from a rich discourse and community of developers. This model is flawed however, in the sense that it would require the user to download and install an entirely new browser. As nearly all commonly used web browsers (i.e. Google’s Chrome, Apple’s Safari, Mozilla’s Firefox) are built upon the aforementioned open source frameworks, it would be ideal to initiate collaborations with these parties, so as to aid in the development of more preservation-friendly development practices. The realization of this model as a browser extension or feature native to these browsers would be a more sustainable model, as it asks less of the visitor, while theoretically offering the same result. While emulation is a term not often used when speaking of web content, that is essentially what the model proposes – an environment that will provide support and access to art objects that are otherwise inaccessible on contemporary systems. However, while previously it was posited that emulation was not a viable solution for the ArtBase, this model is feasible and sustainable, as it provides a singular solution for the majority of the collection.

Migration is the practice of converting digital objects from obsolete formats, to contemporary formats. For example, if the .JPG image format was in the beginning stages of deprecation, works in the ArtBase that employed use of this image format would be identified, and their .JPG assets would be converted to a more stable format. While migration does present a viable solution for the management of digital assets, it assumes a high level of access and interoperability. For example, migrating a format such as .JPG is viable only because it is a format that is interoperable with many different forms of image editing tools. Lossless migration from .JPG to a new standard does not require access to any sort of source code, so long as there are tools that can interpret it. This approach becomes more challenging when considering the whole of the ArtBase, as many works include less interoperable proprietary compiled formats, such as Shockwave Flash files (.SWF), and require access to specific editing software (Adobe Flash) and original source files (.FLA, Actionscript) in order to approach migration. While migration is a fundamental component of preservation, within the context of the ArtBase, it will over the long-term be best suited for application to simple digital objects such as images, sound, and video.

Where migration offers a simple process of continual upgrade, works whose primary form is a compiled piece of software, such as Levin’s Flocuss, require a more involved process – referred to as reinterpretation. [4] When a piece of software no longer runs on contemporary infrastructures, one cannot simply convert it. Reinterpretation calls for delving into the uncompiled source of the software, and repairing whatever is the root cause of its obsolescence. In some cases this may be as simple as altering the format of the compiled software, while in others it may call for a fundamental re-write of the software’s source code. In such cases, this is only made possible by having access to the software in its uncompiled format. In the most drastic of situations, documentation of the functional work, along with analysis of the work’s source can offer a path to creating a faithful reinterpretation. The sense in which emulation is not feasible for the ArtBase is applicable here – the thought of distributing emulators for visitors to the ArtBase to download in order to run the various software based works asks much effort on the users part.

MONITORING A GROWING COLLECTION

With a rapidly growing collection currently containing over 2,500 works, each consisting of complex digital objects, an automated system for monitoring obsolescence is crucial. Although the ArtBase recently adopted a new collection policy that accepts only archival objects, it continues to suffer from the past acceptance of “linked objects.” These works exist solely as records, which link to the actual digital art object hosted by the artist, or third party such as a museum. In such cases, Rhizome has no control of the sustained access to these works; they exist in the ArtBase solely as catalog entries. If the artist removes the work from their server, stops paying for web hosting, or modifies the URL, access to the work from its ArtBase record is eliminated. Efforts are underway to transition these works to full archival records hosted by Rhizome. Fortunately, verifying a URL can be fully automated, yet monitoring anything more complex than a dead URL requires a more nuanced approach. Rhizome is currently researching the implementation of a tool (such as the UK National Archive’s DROID and PRONOM) that will allow for reports to be automatically generated on the digital object representation formats present in a work, which will in turn allow for the identification of works which implement an obsolescent format. The problem remains however that issues of browser support and obsolescence most often do not manifest themselves in a discrete manner that can be identified through automation; there is no way to write an algorithm that asks to search for anything that “doesn’t look right”. In the context of the ArtBase, the most effective means of identifying these complex problems is a human one. Providing users of the ArtBase with a simple and helpful means to report problems with an art object offers an effective means for identifying dysfunctional works. Once a user has reported a work as being in some state of dysfunction, it can be investigated for the root of the issue.

FUTURE INITIATIVES

A major wealth of material not collected by the ArtBase is the ephemera produced by the artist. Whereas the artist working with physical materials produces ephemera such as sketches, plans, notes, unfinished works, and studies, these materials are typically not collected until after an artist passes, or late in their career. For the artist working in an entirely digital environment, what is the likelihood of these peripheral documents surviving? During the life of one artist, many computers will come under their command, and while their finished works may persist in archives, what is to come of the ephemera contained on the studio environment of their hard drive? By definition, ephemera fall outside of the scope of most collecting institution’s immediate interests. It simply constitutes far too much material when considering the sheer quantity and the inability to predict what will be worthwhile. It is undeniable that some day this material will be valued. A unique example where this was executed successfully (through a combination of good fortune, and expert digital forensics) is the Rushdie archive at Emory University’s Manuscript and Rare Books Library (MARBL). Here they preserved and emulated the personal computer of author Salman Rushdie. While Rushdie was not a digital artist per se, the computer was in fact his studio environment. MARBL preserved the ability to observe Rushdie’s digital manuscripts, drafts, notes, sketches, and correspondence. This is a teachable moment in the value of digital ephemera. What provisions can be made to ensure that future generations will have access to not only preserved art objects from our time, but the ephemera produced by these artists? It is in the best interest of stakeholders to strive for developing tools for the artist that will allow for some form of self-preservation, as well as integrating these materials into the scope of interest.

A DEMAND FOR COLLABORATION

For Rhizome and other collecting institutions and repositories, the path forward is clear: interdisciplinary collaboration. Institutional and disciplinary boundaries often keep innovation and progress within their respective silos of knowledge. Within the field of technology there are powerful stakeholders far outside of the art world and museum community, who have made advances and built tools incredibly useful to collecting institutions such as the ArtBase. It is vital to expand collaboration and communication, and for institutions such as Rhizome to seek consultation from such fields. The model of collaboration forged by the Variable Media Initiative is a scalable one. The VMI was intentionally composed of diverse institutions at the top of their respective domains, be it Internet art, performance art, or collections of variable new media. Each institution offered their field specific knowledge, resources, tools, innovation, and research. This aggregation of wisdom is necessary on a broader scale, spanning public and private sector communities of computer science, digital forensics, software development, open source communities, information scientists, archivists and museums. In 2002, Richard Rinehart concluded his paper "Preserving the Rhizome ArtBase" with the following statement, "Rhizome will make a unique, significant and feasible contribution to digital preservation efforts by proposing and testing solutions for metadata and policy as outlined above." In a moment that sees the ArtBase transitioning to a truly standards based archive, this statement remains to be true. Rhizome continues to devote itself to the sustained preservation and universal access to the cultural history reflected by the intersection of art and technology.

ZEUGMA

ANNA HATZIYIANNAKI

«Zeugma» is the title of the New Media and Mixed Media Art Project, inspired from the Hellenistic twin city Zeugma, now covered by the river of Euphrates. So, six Greek young Artists, traveled to Istanbul, also a twin city built on the two banks of Bosphorus to experience a cultural zeugma, in such a way, that to implement it in contemporary artworks.

Introduction

Zeugma was an important Hellenistic city on the opposing banks of Euphrates, in the area of the contemporary South - Eastern Turkey, comprised of the twin cities Seleukia and Apamea.

In 2004, six young Greek Artists, being aware of the Zeugma project, traveled to Istanbul to live in situ the experience of a “zeugma”, in such a way as to allow them to implement the knowledge in contemporary artworks. In the Greek language, “zeugma” means “link”. The term, or word, can be applied to any place where dissimilar elements meet, co-exist and are bridged together in harmony.

They were searching in modern Istanbul for a “zeugma” of Ancient and Modern times, for an intercultural node of East and West. Though the idea to transform the concept of “zeugma” in contemporary artworks was started from the twin Hellenistic city, the workshop finally took place in Istanbul which is also a twin city built on two sides of the Bosphorus.

Istanbul was the apple of Eris among many claimants in the old times, but also the cultural meeting point of ethnicities that were living around the no-border areas of East-Roman, Byzantine and Ottoman Empires. It remains a hub for Balkan – Mediterranean and Eastern areas, a kind of a timeless Cultural Capital. The goal of the Greek artists was to bridge through their artworks concepts like: “Diversities”, “Past and Modern Times”, “Local Culture and Intercultural Digital World”.

Brief Analysis of the Project

Key Notions: The artworks that emerged from that journey - workshop, carry the following key notions: “Twin Elements”, “Vis-a-vis in a Mutual Axis”, “Contra Position”, “Nodal Point”, “Joint”, “Sacred and Profane in a Dialogue”, “Intercultural”, “Inter Religion”.

ART "GLOSSARIES":

They have investigated art "glossaries" to conclude that they may be links among all kinds of cultural diversities.

MEDIA:

They used mixed techniques and media. Techniques like constructions and installations out of Metal, Electric Light and Plexiglas. Media like, Video Installations, Interactive Multimedia Installations, Video Performance and readymade.

THE AESTHETIC IDEA:

Avoid to undermine the autonomy of diversities, but rather link them, building a horizontal network without any hierarchy, like a kind of cultural rhizome. Is this perhaps the bet of the 21st century?

The Artworks

“PRAYER”

By Constantine Tiligadis, Multimedia Interactive Installation, 2006.

Jesus and Allah meet each other harmoniously, into the interactive work “Prayer” of Constantine Tiligadis. It is a Π shaped installation. In its central side, a digital picture is projected displaying two hands in prayer. An audible environment is activated by the visitor’s presence. It is either a Byzantine or a Muslim prayer, depending on where the visitor stands, while it is possible to hear a symphony combining both prayers. Tiligadis ponders on the everlasting subject of Truth. In Istanbul, which is full of temples and mosques, he focalizes on the meaning of the word “faith”, the backbone of every religion according to Emmanuel Kant.

“THE MEMORY OF POLIS”

By Andreas Sitorego, 3D Animation, 2006.

The geographical and urban structure of Istanbul, as seen from Galatas’ bridge, inspired Andreas Sitorego the idea for the digital work “The memory of Polis”. Using a 3D animation technique, he presents three interlocking bones moving very slowly around their common joint, and allowing through their transparent material on their imaginary axis of abutment to slowly emerge a faint kaleidoscope effect. A note of the artist in Istanbul states:

Spirit and matter have been kneaded by the experienced hands of time, offering unsparingly to the next generation the magical remnants of the faiths gone by, etched into the material.

“BORDER”

By Andreas Sitorego, Video Art, 2006.

The artist sets a double projection (on the floor and on the ceiling on the same vertical axis) of a nautical cork that floats on the surface of the water. The viewer becomes a bridge between the elements of air and water, elements that he perceives from two opposing sides. The viewer stands in the middle of the two worlds the aquatic and the ethereal. While on the ceiling, the image of the cork in the water is like someone is watching it from underwater. The other projection, on the floor, shows the cork as it floats on the surface of the sea.

“FEEDBACK”

By Ioanna Myrka, In situ installation, readymade, electric light.

It is an in situ installation, made of used empty carton boxes and electric light. It is the disposable packaging of Today's Consumer Society with standard decals for evaluation and information about the content, identity, distinctiveness and evaluation. For Ioanna, this is

the leftover traces of a civilization that we throw away and in which the air is now stored in those cart boxes. It is garbage, collage and pieces of Time, the image of Polis from afar, a puzzle that is somehow dirty, somehow arbitrary, anarchic and random.

“SPHINX”

By Yannis Melanitis, Video Art, 2006.

The lens focuses on the face of a woman which is stone like. She portrays the new Sphinx. The theme derives from the ancient Greek Sphinx, a hybrid of a triple nature – with the head of a woman, the body of a lion, and the wings of an eagle, a treacherous and merciless creature. Those who were unable to answer the riddle of this mythical creature were killed and eaten by her. The contemporary Sphinx, while talking to herself, places a new riddle:

My definition of Man is not a riddle.... every word I say comes out of my despair about language...
Language is my greatest problem.

“THE HOLY LIQUID”

By Andreas Lyberatos, Installation of 2 sculptures, 1 painting, electric light and readymade objects, 2006. These three works have been fitted in such a way as to create the impression of a sacred place. The central composition is the figure of a human head that insinuates its shape and receive a kind of Holy Communion from the electric light. The other two wall-mounted works are facing each other. One is sculptured while the other is a painted composition which consist of variants of the central figure. The human head opens into two profiles looking at each other while they are connected with thin tubes, representing aquifers that end between the faces in a composition of transparent water glasses. The correlation between the human body and the holy place arises from artist's state:

The body as a building, the face as a whole city, the whole body-city, shaped as a church, fallen on its knees, praying. The shape of the cross on my face.

“VIDEO PERFORMANCE”

By Helena Poca, White dress with hook mechanisms, everyday objects and video projection.

Conclusion

The first presentation of the artworks that emerged from the journey – workshop in Istanbul in 2004 with the collaboration of the Centre for Contemporary Art of Rethymnon, took place in 2006 with a

group exhibition at the archaeological site of artillery tower at Rethymnon, Crete. The project remains open with the same or an enriched form at other cultural Zeugmas.

We can say that this project applies not only to the lost Hellenistic city and to contemporary Istanbul, but also to all Mediterranean areas because this exceptional Sea is a kind of liquid Zeugma among Asia, Africa and Europe.

A PAINTERLY APPROACH TO 3D COMPUTER GRAPHICS

ANTHONY HEAD

This paper is a review and exploration of the work over the last ten years of Light Years Projects, a collaboration between Jeremy Gardiner and myself. It covers in particular how I have explored the notion of a painterly approach to real-time 3D computer graphics. It deals with the tensions, temptations and opportunities that lie in the area where landscape painting crosses with technology, concluding with some of the lessons I have learnt.

INTRODUCTION

For the last 10 years I have worked in the field of digital landscape painting with Jeremy Gardiner, forming the partnership Light Years Projects (www.lightyearprojects.org). Our work starts with the landscape paintings created by Gardiner, and evolves into virtual digital landscapes, through the addition of my programming. During this time we have explored new techniques alongside the development of technology relating to 3D computer graphics but we have taken care to maintain a painterly approach to our work. The opportunities and limitations provided by technology can sometime lead to tensions and influence decisions that we, as artists make, but that is not always a bad thing. This paper explores our projects in terms of a painterly approach and the role of technology in our work.

A PAINTERLY APPROACH

The term painterly generally has two meanings. The first is related to ‘having the quality of expertly brushed workmanship.’ [1] The second meaning comes from the German word term *malerisch* and relates to the use of juxtaposition of colour and tone, as opposed to the use of line, to create form. Wöfflin in *Principles of Art History*, pointed out that “the outlines and forms of some paintings, such as Rembrandt, are indistinct, and as such the viewer’s eye wanders freely over the painting, giving a sense of movement. [2] In a painterly painting, brush strokes may not represent a life-like reproduction, but a deliberate choice by the artist, where they have consideration of shape, colour, texture, light and expression are all used to provide more than a photographic-like result. The term equally applies to modernist landscape artists such as Paul Nash, whose work overtly interprets the landscape through the eyes, mind and hand of the artist.

The paintings of Jeremy Gardiner reside in the painterly and modernist approach. [3] The abstraction of landscape, through shapes, lines and colour represent many perspectives of the landscape and also seasons, times, and eras. The physical approach to creating the paintings includes impasto, cutting, sanding, painting, rubbing and scoring. These combine to form the experience of the painting, not just as a flat picture, but also as a three-dimensional object.

The opposite of a painterly approach is a linear approach, attributed by Wöfflin to the paintings of Botticelli and Vermeer, paintings where the outlines of objects and people are clearly defined, brush strokes smoothed and (in the case of Vermeer) an attempt to create a realistic-looking image.

So why did we choose the medium of 3D computer graphics that has, for the last 20-30 years, been taking a decidedly linear approach to image making, from pre-rendered animations to real-time computer game graphics? The answer is partly because of the challenge, but particularly because of the opportunity to explore this medium in a different way. We wanted to adopt a painterly approach to 3D computer graphics and to try to avoid the goal of realism.

NON-PHOTOREALISTIC RENDERING

The strand of computer graphics known as non-photorealistic rendering has been achieving a *painterly effect*, a simulation of paint-strokes applied a 3D graphics or video scene, for over a decade ([4][5][6][7] for example). However, this is not what I would describe as being a painterly approach. Computer graphic techniques are becoming more sophisticated in being able to analyse scenes and simulate the application of brush strokes to them. But it is apparent that the emphasis found in the literature is mainly on the technical achievement, and underestimates the intention of any artist in taking a painterly approach. Hays and Essa, in their 2004 paper wrote “a need for non-photorealistic rendering and animation is obvious to anyone who has marveled at artistic works where complex scenes and objects are rendered using pen and brush strokes, using lines, colors, and etches.” [4] In 2008, Bhattacharjee and Narayana wrote “The intentions of an artist come out as the aesthetics and expressiveness of the painting. The accurate rendering done by computers fails to provide images with a such a feeling ... Painterly rendering ... can bring artistic abstraction to the rendering and thus mix the computer generated scenes with the hand drawn elements.” [7] These descriptions, and others, seem to simplify the artistic or painterly approach as being something that is reproducible via algorithmic methods. I would argue that this is not the case. A simplified artistic effect is achievable through these methods, but this is not the same as each stroke being deliberately made as part of the creative process, and each part of the composition being considered (sometimes sub-consciously).

I'm not saying that algorithms can't be used intentionally by an artist, in Algorithmic Art, screen, print and plotter based computer art, artists set up the rules that create the subject and content of the picture. But the above papers, take away the role of the artist in the creation of 'painterly' images, in much the same way as I wouldn't claim to have created a watercolour painting by applying the watercolour filter in Adobe PhotoShop.

LIGHT YEARS PROJECTS PROCESS

In the work of Light Years Project's we have a two-stage process. The first stage is the creation of drawing and paintings by Jeremy Gardiner. Because of this, I have not felt the need or desire to simulate brush strokes in the 3D graphics stage, and instead use scans from the paintings mixed with 3D graphical components and events for the second stage. The intention has been to show the actual paint strokes and textures within the finished digital work, and create an infinitely varied painting and an experience.

We started creating our initial project *Purbeck Light Years*, in 2001. We layered cutouts of scanned paintings within a 3D landscape mesh that had been created from satellite data. The terrain itself was of limited resolution and hence all small features were smoothed out, only the hills showed, including the hill of the focal subject, Corfe Castle. Technology forced our hand on the detail shown on the landscape, but the result was agreeable to us. Gardiner's hand drawn representations of the castle, formed overlapping outlines as the viewer roamed across the landscape. We made deliberate decisions about the positioning and texturing of the line drawings. By observing the results of the interplay of the line planes, we decided upon the outcome that we wanted.

Each of the cutouts from paintings had varying transparency. These planes encircled the line drawn Castle focal point and as the viewer moved, the planes overlapped each other. This enabled the image to be viewed in two ways simultaneously; as the illusion of three dimensions, but also, as a two-dimensional dissected image of shape and colour. We selected a number of planes and positioned them randomly around the castle. We did this partly to convert our aesthetics to a rule based composition and also to enable the piece to be co-creative with the audience (as well as being a co-creative partnership between us, as the artists). [8] The audience was able to interact with the piece to create the compositions that satisfy them aesthetically.

Another aspect of our painterly approach to the project was in capturing the visual essence of being in the location. In Gardiner's paintings, colour and light are used to portray the atmospheric changes brought on by the seasons. These variations appeared in the interactive work; the sky and ground was covered in changing textures that subtly evoke different seasons and weather conditions. The light and colour in the virtual work changed, hinting at day and night. The mist would come in and the sound of rain heard. Other natural sounds (e.g. birdsong, wind, crickets) were also audible, some specifically located in the landscape (co-creative audio composition) and other sounds that occurred at programmed intervals. So in *Purbeck Light Years* we applied a painterly approach to audio media as well as visual media, in terms of composition, blurring one sound into another.

LIMITATIONS OF TECHNOLOGY

Our view when working on this project was to use a painterly approach to many aspects of composition across this virtual landscape. However, there was one aspect of painterliness that we were not able to

portray, due to the limitations of the platform, Macromedia Director, that I used to program the project in, which didn't allow bump mapping or shadowing. We couldn't show the physical texture that the original paint had, and thus revealing the painter's marks, clearly. But also, as we mentioned earlier, we didn't want to create an effect to achieve this either. Once this work was completed in 2002 we exhibited it over a period of five years. [9]

By 2008 technology had moved on and so had our knowledge of 3D graphics, we now chose to use a new platform, Unity Technologies' Unity3D, which allowed bump-mapping and was easier to use for our work. Graphics cards had and still are improving, enabling us to have more detail, larger textures. Processing power had increased allowing for more computational options. We started thinking about a new project where we would be able to take advantage of newer 3D graphics technologies, in hope that it would open up more possibilities in our work. We wanted to maintain our painterly approach. But likewise, we wanted to be more ambitious.

DEVELOPING A NEW PROJECT

Thus we began an eighteen month long development period for our second project. New paintings were created and new programming techniques and ideas were explored. The resulting work has had several permutations since its premiere in March 2009, *Jurassic Light Years* (Chelsea Art Museum, New York, USA, March 2009), *Light Years: Jurassic Coast* (Electronic Visualisation and the Arts Conference, London, July 2009) and *Light Years: Coast* (Lighthouse Centre the Arts, Poole, UK, June 2010).

In terms of ambition, we were keen to expand the scale of the project, increasing the size of the landscape that it deals with, in order to create a larger experience. Whereas *Purbeck Light Years* dealt with a mile radius around Corfe Castle, *Jurassic Light Years* dealt with four miles of coastline and *Light Years: Coast* with fifteen miles of coast. The terrain we used was more detailed, and we were now using two-metre resolution Lidar data to create the landscape, instead of lower resolution satellite data. This meant that rough forms of trees and buildings were visible and could be lit-up and shadowed. These new projects featured the added dimension of English Channel, leading to a quest to explore different ways to represent water. The idea of moving waves and reflections was attractive, as it meant that the reflections distorted the imagery above the water. I used algorithms that fairly realistically mimicked real ocean waves. These waves were connected to an Internet data feed of local weather information. The wave heights and tides were affected directly by the information fed into it, which provided an interesting direct link to the real world.

In *Jurassic Light Years*, I improved the rain system from what I had used in *Purbeck Light Years* by using particles to simulate rain. This gave a more dramatic representation of rain, but too many particles affected the frame rate. Keeping a high frame rate was an important factor in making the experience immersive, as a stuttering image, was uncomfortable to watch. There was considerably more landscape mesh detail as well, and bump mapping on the cutouts of paintings, which showed the texture that appears in paint strokes of the original paintings.

TENSIONS WITH TECHNOLOGY

I spent a lot of time developing these techniques, and this led to a tension. Not so much in what the technology could do, but rather in the result of what it enabled me to do.

As I have mentioned, we had taken on an increasingly ambitious project by representing an experience of a much larger area of landscape. Our painterly concept, of using overlapping planes to create a tension between the 2D and the 3D required approximately 50 planes in *Purbeck Light Years* but to achieve the same density of planes in *Jurassic Light Years*, we would have had to use thousands. Although this was technically possible, it was not artistically feasible. As a result of this issue we ended up with a much sparser landscape in *Jurassic Light Years*.

Light Years: Coast, set in an even larger area of land, had planes that rarely intersected each other, but showed larger sections of paintings, roughly aligning with their viewpoint in the landscape. This meant that the work was part interpreted simulation and part painterly experience. The viewer took a virtual boat ride along the coast, but the visual features were elements of paint suggesting the geology of the land.

Another point about these newer projects is to do with interactivity. They are deliberately passive, less co-creative experiences. This was a decision we made based on audience observation of *Purbeck Light Years*; that many people just stood and watched, instead of using the joystick to interact with the piece. The more passive viewing approach meant that we directed the viewer more. However, this was more akin to being on a boat journey. The co-creative element was reduced and the opportunity to question the two-dimensions versus three-dimensions happened less frequently, but I believe with more anticipation.

Overall *Light Years: Coast* has developed into a virtual landscape experience, where the weather is more clearly defined than in *Purbeck Light Years*, where there is greater contrast between calm and stormy conditions, enhancing the emotional impact.

CONCLUSION

The improving technology, and my own learning on how to harness it through programming methods such as Shader programming, have had a prominent influence on the *Light Years: Coast* work. Technology, or rather the excitement and opportunities of it, *has* affected our painterly approach, by drawing me into wanting to do something bigger (and hence better). The result was, however, different to our original project, it was more 'linear' on the whole. Technology had broadened and challenged our work and also created new possibilities.

The steep technical learning curve I went through has left me with a new knowledge, and control of the medium, that we as Light Years Projects can now apply to new work. By manipulating the language of 3D used in computer games, we can keep true to our original aims of applying a painterly approach to a virtual artwork, to a digital landscape painting. Our next landscape project does not need to be bigger, in terms of the landscape it explores, but will be more focused, and enable us to use the knowledge we have gained of the technology to apply a painterly approach to the work.

BODY AS A WEAPON AIMED AT YOU

Marta Heberle

The body transformed to data serves as a powerful weapon of the state. It becomes a biocapital, a carrier spreading the disease at the same time entangling itself in the network of politics, medical services, information distribution, transport, databases etc. The war is being fought via biopolitical body, a gun pointed at you.

The functioning of today's state oscillates around the bodies, the population, the life itself. Life is included into the domain of politics, it is an arm of discipline and control, and it drives biopolitics. The currency of biopolitical state is bioinformation. This data is a universally traded commodity. It is of great value to the security state as it allows for the management, supervision regulation and control of population. A valid comparison can be drawn between the attitude expressed towards bioinformation in modern security state and the Marxist notion of "commodity fetish". Different types of bioinformation are extracted, gathered, accumulated and globally exchanged; from various forms of individual identification, all types of health data, health insurance, through consumer information, to the surveillance of bodies in the public space.

However, it should be pointed out that this information is of a very specific character. In the context of contemporary biopolitics, Eugene Thacker observes, that the information of which we're speaking, the main focus of modern biopolitical state is not only immaterial: "Biopolitics mediates between genetics and informatics. (...) In biopolitics (...) information is not exclusively immaterial or disembodied; information in biopolitics is precisely that which can account for the material and embodied and, furthermore, that which can produce the material, the embodied, the biological, the living - <<life itself>>. Information is the point of mediation through which biopolitics regulates genetics and informatics into a sophisticated mode of governmentality and control." [1] So, one might say, that we're dealing with a unique situation in which flesh is made data and data is made flesh. Thacker delivers examples of this duality of bioinformation: "Genome databases, biological<<libraries>> of cell lines, patient databases at hospitals and clinics, prescription databases, insurance databases, online medical services, and a host of other innovations are transforming the understanding of <<life itself>> into the understanding of informatics. (...) The pills, therapies, test results, diagnostic measures, insurance rates and foods are the material output of this informatic view. In rarer cases, cell therapies, in vitro fertilization, genetic screening, and tissue engineering are a literal instances of this biopolitical condition, in which data is made flesh." [2]

Nevertheless, despite the materiality being an intrinsic feature of bioinformation, once the data is extracted from our bodies, in most cases it becomes inorganic and extraneous. It becomes an abstract code with which we're unable to identify anymore. Our bioinformatic patterns evoke a feeling of estrangement and uncanny unease; what once was homogenous and coherent becomes fragmented, translated into numbers or organic samples and processed to the point when we cannot perceive it any other way but as an abject, which gives rise to rejection. We seem to have reached a point, of which Foucault was speaking in the context of utopian body: "Utopia is a place outside all places where I will have a body without a body." [3] It's not the case that our moist intestines have dried to bytes. Their materiality exists, but as they become incorporated in the intertwining networks of medical services, economy, politics, culture, media and third-party companies, they become owned. Whether in a material or immaterial form, they are absorbed by interlaced networks and then exchanged, circulated and

distributed. In the constant fluid flow of biological exchange, different subjects, different power vectors, appropriate the value of biological information, be they hospitals, pharmaceutical companies, security services, government agencies, independent individuals etc. In biological exchange, this networked, mobile bioinformation is both the input and the product.

Yet since it was directly stated that in the constant process of bioexchange, bioinformation becomes appropriated, fundamental questions remain to linger: Do we own our bodies at all? Do we have the right to trade them, to sell the bioinformation derived from them? Why does my body exist more in the banks, databases than it exists for me? Why has my essential data been converted into commodity and why do influential companies, pharmaceutical moguls, ruling elites, security services freely use and trade it without even bothering to ask for my consent? How is it possible that once it has been extracted from me I am unaware of what my samples are used for and unable to decide about them, although they are my very property? Perhaps we should raise these objections at the level, where biodata is being collected, before it's incorporated into the circulation of the global networks.

Consciousness of ways of gathering bioinformation is of great importance. For are we aware that our every step, every credit card transaction, every email are watched, tracked, filtered and thrown into the fluid information networks? One of the "terminals" that constantly monitors the activity of biopolitical bodies in public spaces turning it into data, are surveillance cameras. They're almost everywhere; the ruthless gaze watches the streets, workplaces, means of public transport, offices, institutions, parks etc. Unfortunately, there are little chances of avoiding their omnipresent eyes. Since they cannot be eluded, they become naturalized and grow into the city's landscape, at the same time abolishing the uneasy feeling of being watched and also, our alertness. Another restrictive branch commonly utilized by security services are biometrics. These are technologies, which allow for the recognition and identification of humans upon their measurable physical or behavioural features. As Emilio Mordini and Sonia Massari indicate: "Current biometrics include fingerprints, ultrasound fingerprinting, iris scans, hand geometry, facial recognition, ear shape, signature dynamics, voice recognition, computer keystroke dynamics, skin patterns, foot dynamics. Future biometrics (second generation biometrics) include neural wave analysis, skin luminescence, remote iris scan, advanced facial recognition, body odour, and so on (...) Also behavioural biometrics – which measure behavioral characteristics such as signature, voice, keystroke pattern and gait – is becoming increasingly important." [4] These systems are becoming commonly used, consequently every time we cross a border, undergo a routine medical check up, visit a bank, or even try to enter a public institution, our intrinsic, innate characteristics are being gathered and included in a database as well as in a global stream of interconnected networks. This biodata may serve commercial institutions, pharmaceutical companies, statistical bureau, and passport control services at the airport just to name a few. They prove useful in cases of profiling people, they may decide upon inclusion or exclusion facilitate human segregation alike eugenics, reveal weak points in human constitution thus delivering instructions where to strike to crash our bare systems or even providing formulas for creating a bioweapon capable of exterminating particular ethnical groups due to their slight DNA differences.

What has to be necessarily highlighted is that these biometrical technologies don't only gather one type of information at a time, relevant for the identification of biocitizens. To use a simple example, when a person is having his or her iris scan taken, additional data such as eye colour, the complexion, which may give some hints as to the ethnic origin, and other signs revealing for instance certain health problems are being collected. Then this data is dispersed and perhaps it doesn't serve only the purpose it was primarily destined for. Situations of this kind are spoken of in terms of "function creep". "Function creep" is the term used to describe the expansion of a process or system, where data collected for one specific purpose is subsequently used for another unintended or unauthorized purpose" [5] This feature cannot

be expelled though, as it is a result of the ways biometrical systems operate and also a characteristic of our fleshy envelopes.

What Mordini and Massari also observe is that article 7 of the EU Data Protection Directive firmly states, “No data collection can go unnoticed by the subject that is being monitored. The goal is that the individual is aware of all types of data about him/her that are collected.” [6] Perhaps this could be a solution to the oppression and terror experienced in almost any dimension of life by biopolitical bodies if it wasn’t for the second part of this article which abolishes binding force of the first paragraph predicating, that it is not applied in cases of ‘processing of data relating to offences, criminal convictions or security measures.’ [7] The law collapses into itself.

Where state reenacts the spectacle of evil, biopolitical bodies choose to accept the ever increasing strengthening of defenses, regulations, as well as terror and hysteria that accompanies them, supporting the conviction that it’s all being done for their protection and safety. Roberto Esposito, in his analysis of the thought on immunization brought by Niklas Luhmann underlines, that “systems function not by rejecting conflicts, but by producing them as necessary antigens for reactivating their own antibodies.” [8] The metaphor of vaccination seems exceptionally accurate when applied to the mechanisms that constitute the roots of security state. Humans intoxicate themselves with a substance which is in a relation with the disease and which may procure some of its symptoms claiming, that this treatment increases their chances to last. But is it vital that we accept and, what is even worse, rationalise this violation, constraint and terror? Are we truly condemned to this destructive constellation of power?

As I have emphasized earlier, the consciousness of mechanisms driving security, or shall we rather say terror state, is of crucial importance, and to some extent it may help to limit the participation of biobodies in the superiorly induced social hysteria. If we remain unaware of these processes, and, what’s even more important, if we don’t realize the position in which we are put, we become pawns in the game. What’s especially important is to simply think for ourselves instead of commissioning this task to the power. Otherwise, choosing ignorance and randomly accepting the arguments delivered by the authorities, we, our biodata, will become a commodity sucked into, and traded via a global network as we perform simple routine activities of everyday life.

Slavoj Žižek suggests that “The problem is not terror as such - our task today is precisely to reinvent emancipatory terror.” [9] Assuming that emancipation is the action of freeing oneself from restraint, I understand this thought as an expression of a necessity of a quest for smart ways enabling biocitizens to limit the destructive impact of security state functioning. But what exactly could these ways be in practice? Firstly I would like to underline what I have stated above, that consciousness is the key stage in directing the guns aimed at biopolitical bodies the other way. It’s a weapon, and, to some extent, also a remedy. To give a simple example: in an outbreak of influenza caused by a new, not thoroughly recognized mutation of a virus, one may refuse to “protect” himself with a vaccination from a questionable source, prepared quickly by some influential pharmaceutical mogul, as an answer for the threat to the body politic, thus eluding the participation in the mass societal panic. On the other hand, there are also other, more radical and drastic possibilities of intervening in the mechanisms of security state, such as adopting its own methods, which, in this case means responding to terror with terror. However, the most common reaction - traditional attacks, be they plane kidnappings, booby-traps or assassinations of people from the pedestal of power, hardly ever prove successful and reach the goal of terrorism which is, as we know, not the military victory, but a change in sociopolitical structures. At the same time, it has to be acknowledged that such operations may easily turn against their originators. As Chomsky says:

“React with extreme violence and expect to escalate the cycle of violence, leading to still further atrocities, such as that is inciting the call for revenge.” [10] Thus, it has to be remembered that, to paraphrase Jack Parsons “Terror is a two edged sword”.

It’s particularly for this reason that I see a great potential in utilizing bioweapons for the purpose of counterterrorism, understood here as reacting to the oppressive actions undertaken by state. Although it’s a common persuasion, expressed by great number of experts dealing with the subject of bioterrorism, that bioweapons are completely useless, I find it hard to agree with this perspective. Steve Kurz, in his profound study on the possibilities of bioterrorism, underestimates the effectiveness of bioweapons directly stating that “biological weapons are only what they are—useless junk.” [11] However, I attribute the attitude expressed by Kurz to the fact that he focuses mainly on old, exhaustively researched viruses and bacteria and also examines bioterrorism in terms of military victory and statistics of casualties, not in the symbolic sense. In my opinion, in the conditions of easy accessibility of biodata gathered in databases (for instance open databases facilitated by academic environments or individual scientists), possibilities of intercepting information exchanged in various networks, and a great amount of know-how available at every terminal capable of connecting with the Internet, the chances of producing a new, unknown, transgenic supravirus able to decimate populations, are very high. After all, benefiting from the databases is nothing but getting our biodata back. “In the future, terrorists will be individuals or like-minded people working in very small groups, on the pattern of the technology-hating Unabomber, who apparently worked alone sending out parcel bombs over two decades, or the perpetrators of the 1995 bombing of the federal building in Oklahoma. An individual may possess the technical competence to steal, buy, or manufacture the weapons he or she needs for a terrorist purpose; he or she may or may not require help from one or two others in delivering these weapons to the designated target. The ideologies such individuals and mini-groups espouse are likely to be even more aberrant than those of larger groups. And terrorists working alone or in very small groups will be more difficult to detect unless they make a major mistake or are discovered by accident.” [12] Taking into account the context of bioterror, I fully agree with Laquer’s opinion, especially on the easy accessibility of materials needed for a terrorist attack and the possibility of operating alone, yet for me, the future is now. It is precisely now that biocitizens may produce subtle, invisible, odourless, undetectable lethal microbes. It is now that they may use their bodies as incubators for viral replication and as carriers spreading the disease at the same time. The disease may be distributed easily and at a great speed through many channels, as a matter of fact, through all places of human flow like transport network, shopping malls, public institutions, schools, workplaces etc. The infection may also occur on a global scale. The only condition is to create yet unknown, unfathomable organism precluding the attacked side from defending. The surprise itself works here as a weapon.

Another option of addressing the issue of unjust practices of security state is interpreting them through the domain of art. Artists may strike various attitudes and one of the commonly used to engage in a critical judgment is “parasitical” feeding upon found sociopolitical structures in order to subvert them and blow their foundations up from the inside. Interesting examples are delivered by Institute for Applied Autonomy in the project *iSee*, which is a web-based application enabling users to move freely around the city space avoiding the gaze of CCTV cameras, by BIOTEKNICA collective, whose interventionist art project raises the issue of commodification of live and of generating and trading organisms on demand, or the *Molecular Invasion* by Critical Art Ensemble, which takes up the form of scientific theatre of participation intended to reverse the process of genetic modification of groceries through experiments with non-toxic, widely available substances.

These are only few examples among a great number of artworks devoted to the issues of various implications of the mechanisms, which drive security state. Unfortunately, the scope of this publication is too limited to elaborate on this point. However, I would like to point to the fact that such artworks not only function in the domain of art, but also effectively intervene in the social order. They make open what was obscured, they uncover what was meant to remain secret and exclusive, thus abolishing the hierarchy present in security state, and moreover, they deliver practical methods of opposing detrimental methods. Since works as such don't confine to the aestheticization of life, rather overcome the distinction between the two dimensions and cause factual changes in the hyperreality of security state, then, perhaps, avant-garde hasn't, as some art critics have claimed, suffered defeat, but right now is at its triumphant position.

THE ART OF LIVING SYSTEMS

Marta Heberle

The notion of life is difficult to define, thus one, universally adopted definition simply doesn't exist. Where does life start? Is it on the level of cells, tissues, the organism? Where can we draw a line separating that what's living from the dead matter? In my paper I would like to reflect upon a group of artworks which literally utilize ephemeral cases of life.

Definition of life is blurred by its nature [1]

The notion of life is difficult to define, thus one, universally adopted definition simply doesn't exist. However, it may be assumed that the most important characteristic of life is a constant exchange of matter and energy between living organism and its environment and the ability to replicate or reproduce. Such dim explanations, questioning the ability of creating one homogenous answer to what exactly the term "life" means, are delivered by many popular encyclopaedias as well as scientific publications. The basic feature of life mentioned by those definitions, also doesn't entirely solve this highly problematic issue. For, is it possible to speak of life in the case of cultured tissue, in the same way as we speak of a living organism from which it was extracted? Where does life start? Is it on the level of cells, tissues, the organism? Where can we draw a line separating that what's living from the dead matter? There are many different definitions of life, which perceive this compound phenomenon from different angles, which take into the account its various aspects. Among many, we can mention reductionist definition, thermodynamic definition, cybernetic one, or a definition founded on the life functions of organisms. The answer to the question whether a given phenomenon can be perceived in the category of life, depends in prevailing degree on the definition we adopt, as well as on the arbitrary decision of a person reflecting on this subject. This ambiguity and indeterminacy of methods we use to research this matter are problematic and raises doubts, whereas crucial decisions often have to be made by means of precedent. Where paralogy is the best methodology available, questions still remain to linger: on what level of cell/ tissue complexity can we speak of life? What do we perceive as an entity? Can life be reduced to numbers, codes, or algorithms? Having these issues in mind, I would like to reflect upon a group of chosen art works, which literally utilize ephemeral cases of life.

For the art works into which I will take a deeper insight, I proposed a term "the art of living systems" serving as a common denominator. These artistic projects focus on particularly problematic cases of life, on the life that is liminal, ephemeral and eludes definition.

A-vo/ve is an installation created by Christa Sommerer and Laurent Mignonneau, which enables the generation of artificial ecosystem inhabited by creatures which are forms of artificial life. Users design their 3D beings which cohabit the simulated environment, by means of defining their shape and look via a touch screen. Then their image is being projected onto a mirror placed in the bottom of a water-filled pool. The artificial habitat is ruled by the brutal principle that the strongest will survive. Artificial creatures manifest activities characteristic for those observed in the animal kingdom; they compete with each other trying to accumulate as much energy as possible. The predators kill the weaker and take over their energy. The creatures, which survive for a long time, are capable of reproduction and their offspring's carry their genetic code.

The notion of artificial life (*A-life*), was first introduced by Christopher Langton during the conference in Santa Fe in 1988. "It is the name given to a new discipline that studies "natural" life by attempting to recreate biological phenomena from scratch within computers and other "artificial" media. *A-life* complements the traditional analytic approach of traditional biology with a synthetic approach in which, rather than studying biological phenomena by taking apart living organisms to see how they work, one attempts to put together systems that behave like living organisms." [2] In this extension of the empirical foundations of biology beyond the carbon chains of earth-based organisms, artificial life can contribute to the theoretical biology by situating life as we know it in the broader context of life as it might be." [3]

The substantial value of *A-volve* is blurring the line, which separates the two worlds, the real, and the artificial one. It is achieved mostly through the interference of interactors into the artificial ecosystem and also through the fact of reconstructing the natural laws in artificial ecosystem. The authors suggest, that "the visitor becomes a part of the evolution system, a partner to virtual organisms, he gives and promotes «artificial life»." [4] Although the above-mentioned definition gives an answer as to what artificial life is, some doubts are raised as to its very nature. Is artificial life only a simulation of the real one? Is it a reconstruction of thoroughly investigated properties of life? Or maybe it is, in a sense, and independent creation that not only imitates certain pattern but also at some point escapes control and governs itself with its own laws? We may ask: is there in artificial life actually anything that we, in common terms understand as living? This notion itself is an antithesis. Lou Bec states, that "artificial life is only a construct that accommodates a tensorial space." [5] The words "construct" reminds us of the fact, that *a-life* is only a creation that exists upon a certain agreement. And although in the case of *A-volve* we are dealing with behaviours and processes similar to those occurring in real life, it is yet only a similarity, whereas the life lived by the creatures is only...artificial.

Carnivorous Domestic Entertainment Robots is a project, which consists of a number of works, which, being themselves artificial forms life, make use of the life of other organisms. The artwork created by James Auger, Jimmy Loizeau and Aleksandar Zivanovic, is a series of carnivorous robots, which manifest similarity to exclusive furniture or luxurious objects of everyday use. Yet, they're not as nice as they appear. In fact, by the use of microbial fuel cell, they imitate the strategies of predatory insects, reptiles and plants. Some of the dangerous devices were created upon the rule of mimicry. For instance the *Lampshade robot* is a lampshade whose form is similar to that of a carnivorous plant. Through the holes in its spherical construction, a light, which attracts insects, is being emitted. Once the insect falls onto the other side of porous surface, its unable to free itself. The treacherous ambush makes use of its death, transforming it into the energy which fuels led lamps at the bottom of the lampshade.

The functioning of carnivorous robots may be described as a recycling of life. For they use the existence of small, fragile and short-lasting creatures that would sooner or later be destroyed anyway, such as moths attracted to light. The architecture of the devices as well as the use of microbial fuel cell solve the issue of the corpses of little animals, which die unable to escape from our houses. Silent murders committed by the machines give rise to a peculiar chain of alimentary dependences in which the robots feed upon real life that becomes their driving force. In this merciless system, the biological life is literally transformed into energy, which then is used to support some simple mechanism. At the same time an important fact is being brought up; that the energy is pulsating in every living organism and that there is also a possibility of extracting it.

On one hand, we may assume, that the technology subjected in this artwork to biologization offers the subjects that are caught in the deadly trap a kind of afterlife, or the extension of life. The time of light

emission of a little led lamp, most probably exceeds the length of their existence. The death of little organisms is in a specific way productive, thus we can think of it as of a sacrifice of real life for the behalf of the artificial. However on the other hand this project places its audience, or the owners who decide to buy such utensils in an uncomfortable position, making them the viewers of a brutal show. Carnivorous, cruel *biobots* take away the right of living organisms to natural death, literally extracting the energy from them. This work raises questions as to whether such life recycling, and instrumental approach towards it, not only for utility purposes but also for entertainment is moral? Is there any justification to dispassionate observation of a transformation of life resembling the position of audience during bloody fights of the gladiators?

Another artwork focuses on a highly controversial and problematic issue - the *semi* life. It explores the issue of semi life thoroughly, which results in art projects founded upon tissue cultures. Oron Catts and Ionat Zurr, artists cooperating with the centre for research as a *Tissue Culture & Art Project (TC&A)*, proposed a series of artworks under the name *Victimless Utopia*. In my paper I would like to focus on one of them, entitled *Disembodied Cuisine*.

The authors decided to deal with the hypocrisy surrounding the discourse of ethical food, which allegedly causes no victims. For this purpose the gallery space has been transformed into a laboratory. Inside it, extracted muscle cells of frogs were turned into half- living sculptures, destined for consumption purposes. The animals that were the cell donors weren't harmed in the experiment. The material collected from them via biopsy was placed onto biodegradable polymer construction and placed in a bioreactor. Then, the tissue cultures were „growing” in the conditions resembling those of the donor's body. The project culminated in a ritual feast, during which the visitors consumed the cultivated steaks, at the same time killing half-living entities.

Tissue is generally described as a collection of similar, organised cells, which perform a definite function, whereas tissue culture is a technique, which consists in isolating little fragments of tissue from the body and cultivating it in a dish containing appropriate nutritious substances. While the body is unable to do without organs and tissues, they can fairly well do without it at the same time fulfilling their specific function. Catts and Zurr suggest that it is a new type of living, thus it needs a new ontology and new taxonomy of life. [6] It is then a sort of a part life, a kind of half- living entities. „When cells and tissues are removed from the context of the body and kept alive, they are also stripped of many aspects characteristic of what is assumed to be a living entity. They are kept alive and raised in a technological environment, which serves as a surrogate of the body. But in the very basic sense they represent the bare life.” [7] Then what precisely are those half-living entities? How should they be perceived? What is the point at which we can speak of life? Can the level between the cell and an organism be described as life? The tissues extracted from the body are situated between that what is living and that what is devoid of life, they are new entities, liminal, ephemeral and undefined, and they completely elude both the biological and cultural classifications. The notions defining body as a whole are inadequate to speak of these phenomena. If we try to describe them in traditional terms, then we will come to a conclusion that they are neither alive nor dead.

The works I would like to turn to next, are similar to *Disembodied Cuisine* in the aim of creating a system providing incubatory conditions, which would protect life and ensure its development. Whereas in the former project the simulation of natural conditions prevailing in the organisms of donors was only one of the conditions necessary to maintain fragile entities alive, creating a biological habitat, a system in which life is possible determines the direction of artistic research of Zbigniew Oksiuta. Their final goal is, as the artist claims, the creation of „autonomous, biological, self-replicating system for one person. Such

system could be the size of a cell, a pill, a fruit a house, or even a biosphere. It could also exist in different environment: on earth, underwater and in the outer space.” [8] The project on which Oksiuta was working between 2003-2007, entitled *Space Garden*, was supposed to create a see-through polymer bubble filled with air in cosmos. Inside this isolated biosphere, a garden would bloom. On Earth there are prototypes of Space Garden simulating the parameters and the evolution of this process. They are appropriately miniaturised and they use a klinostat – a tool used for the research of the force of gravity on the growth of plants. Another project, *Plasmalema*, was an attempt of creating a habitat, which would provide conditions allowing humans to live underwater. This work, as most in Oksiuta’s output has a shape of a transparent bubble. It was made with the use of *Spatium Gellatum* method, which enables the creation of space structures from biological polymers : soft, permeable membranes, that at the same time protect the life inside. The space enclosed by this elastic cover was filled with *perfluorocarbon*, a substance allowing humans to breathe underwater with liquid.

The peculiar works of Oksiuta remind independent planets on which, or maybe it should be said, inside which – a life exists. They resemble a separate world, functioning on its own rules. A world that is autonomous and closed, as if in a crystal ball. They inspire to reflect upon questions such as where else and on what scale can life exist. The artist declares that for him the most important thing is the ability of living systems to self-organize, thus he tries, on the rule of analogy, utilize this rule in his projects. Those, and other artworks of Zbigniew Okasiuta, which explore the subject of biological habitat, raise several questions regarding life, for instance: how and where can it exist? The spherical micro worlds are like small, safe rooms, incubators, which export life into inaccessible, dangerous or potentially lethal territories. Bringing the life space of organisms to a tiny sphere can be also seen in terms of looking for an answer to ever pervasive questions: on what scale can life exist, can it function as an isolated, self-sufficient sector. We should also reflect upon the question what kind of life could inhabit the miniaturised ecosystem compounded by the artist. Although the transfer of a human being into such conditions, given the account of its complexity, seems completely impossible for now, the hermetic systems can serve as a living space for autotrophic plants and also tiny organisms such as bacteria. Sometimes, the bubble space structure itself is also being described as living thing. It undergoes transformations and reacts to stimuli from the outside. Perceiving a frozen, motionless architectural object, whose activity is not fully noticeable and clear, as living, seems like not particularly adequate and accurate. But I have no doubts that the works aiming to create a *Biological habitat* can equally well be called systems for life.

The last art project, at which I would like to look closely, focuses on displaying one aspect of human life, one of the indications of human physiology. There are some circumstances, upon which this project can be compared to the living sculptures of Oksiuta. For both *Cloaca* created by Wim Delvoye, of which I want to talk about and the works of polish artist conduct an experiment, which consists in the idea of transforming the natural scale of phenomena and exporting it outside its natural context. The project of controversial, Belgian artist is a synthetic digestive system extracted from the primary source of the body and shown in a multiple enlargement. The scandalous installation simulates one of the processes occurring in the insides of the living organism, and in a sense it refers to the famous Vaucanson mechanical duck, which was an attempt of creating an equivalent of digestive system. The contemporary *Cloaca*, synchronized with technology, simulates the activity of human digestive system with great precision. Artificial organs perform different functions. There is the oral part, the stomach, and the anus. Into the artificial organs, acids and enzymes are being introduced, enabling the digestion of food. Whereas the human organism aims to fulfil the need of supplying the nutrients to survive, the only aim of *Cloaca* is the production of excrements, the waste products of metabolism. Some specimens resemble a row of containers, while others look like washing machines connected with a net of cables and tubes. Although the machines simulate transformations occurring in the fleshy, moist human body, they do not resemble

human being at all. „ The shocking thing is that it doesn't look like a human being. The shocking thing is that it's like a wheel. The wheel isn't trying to look like your feet, but it does the same thing as all feet do. [...] It's a robot in a way, but it's not trying to look like the gastrointestinal system. It's not trying to be anthropomorphic. It doesn't try to look like a human being. It's a live thing...” [9] But do containers, tubes and filters connected into a whole imitating human digestive system in any way remind the living entity? The metal parts, despite the ability to produce substances universal for human beings, seem to be devoid of life. Yet the author of this peculiar installation arrives with an important argument: „Once the machine is installed in a museum, it is a live thing. Even when the museum is closed the machine is fed everyday, because in the organs, there is real human stomach bacteria.” [10] It is then precisely the system of different bacteria enabling the decomposition of nutrients that is alive. The regular feeding of the machine equals supporting the ephemeral life of weak strains of beneficial bacteria. The *Cloaca*, like every living thing, is sometimes capricious when it comes to some kinds of food. In contrast to the Vaucanson duck, it not only simulates the functioning of digestive system, but it also precisely simulates digestive processes, making their final product almost impossible to distinguish from the one produced by the human organism.

The substantial issue in the context of this installation is also the biologization of technology; what in normal conditions is being performed by the moist machinery of the organism, can be equally well conducted outside the context of the body by a cold metal mechanism. The aspect of care, which is manifested in the need of feeding the *Cloaca* regularly, as well as the impossibility of turning the power supply off the reminds us of the fact that we're dealing with a living system, or rather a biological system of bacteria strains, which support the artificial system.

THE DISTURBED DIALECTIC OF LITERARY CRITICISM

DAVIN HECKMAN

This paper discusses the relevance of database projects like the Electronic Literature Directory. It is a call for criticism that is technologically appropriate, ethically engaged, and culturally vital.

In *The Phenomenology of Spirit*, Hegel describes the dialectical process:

"The bud disappears in the bursting-forth of the blossom, and one might say the former is refuted by the latter; similarly, when the fruit appears, the blossom is shown up in its turn as a false manifestation of the plant, and the fruit now emerges as the truth of it instead. These forms are not just distinguished from one another, they also supplant one another as mutually incompatible. Yet at the same time their fluid nature makes them moments of an organic unity in which they not only do not conflict, but in which each is as necessary as the other; and this mutual necessity alone constitutes the life of the whole." [1]

Viewed from within the Hegelian process, the Real is positioned outside its present manifestations, consisting, rather, of the dynamic processes that comprise its totality.

This insight, crucial to critical practice, requires revision in light of technical change. By revision, I do not mean that we need to fundamentally alter Hegel's argument, I only mean to suggest that we see this passage with respect to new temporal modalities that have shaken up the pursuit of knowledge.

The field of Electronic Literature is characteristically engaged with this disturbance in the dialectic. A casual glance will reveal that there are many significant developments in the field that, had they happened over a longer timeline, would likely be much easier to sort out. Take, for instance, the body of works known as "Hypertext fiction," which represent the closest thing Electronic Literature has to a sustained, stable format. If we track literary hypertext along the history of Eastgate Systems, we are looking at an aspect of the field of electronic literature that dates back to the company's founding in 1982 (though Eastgate's first literary hypertext, Michael Joyce's *afternoon, a story*, was first published in 1987). If we broaden our definition to include interactive fiction and text-based computer gaming, we can push the timeline back to 1975, with the creation of *Adventure*. Beyond this, we can trace the form back to the "Hypertext Editing System" by Ted Nelson and Andries van Dam in 1968. In any case, the history of this particular literary form is a half-century old at its most generous estimation, but it really isn't until Eastgate Systems emerges as the first commercial publisher of Hypertext as Literature, that we see a committed effort to the literary exploration of a particular form, with the bulk of their offerings published in the 1990s. If we add web-based Hypertext fiction to this timeline, that would add to the overall number of works available, but it would still distribute the bulk of creative output over two decades, and would place a massive technical innovation smack in the middle of this arc. [2]

To put this in perspective, one might juxtapose this to the history of the novel which, even at its most conservative definition, spans three centuries. If we want to consider a genre, say, the Gothic: Over 70 years pass between the publication of Horace Walpole's mess of a book, *The Castle of Otranto* (1764) and Edgar Allen Poe's elegant perfection of the gothic in "The Fall of the House of Usher" (1839). Though Franco Moretti has made a convincing case for a more compressed periodization of generic eruptions,

my contention is that this cyclical activity is evidence of the grand dialectical process within which durable forms achieve their refinement, a point which does not conflict with Moretti's model. [3] In other words, historically, the time of literature has been slow and staggered. The kind of back and forth between the creator of a work and its critical reception, followed by a modified approach, and yet more criticism, has simply been short-circuited by the rate of change.

To frame my argument within a more contemporary point of reference, Alain Badiou's notion of "the set" consists of the range of knowledge and the logical potentiality framed within its structure. A "truth" is that which exceeds the bounded structure. This point of rupture is perceived as an "event." [4] If we consider the set and its redefinition by truth as marked by an event, we can rethink what Hegel aims to describe without becoming mired in chronology or bound to fatalism.

We can imagine a horizontal vision of this dialectic, that steps beyond the sequential process of thesis, antithesis, synthesis that seems to favor the vertical progress of the historical from its zero point towards the future. In other words, I mean to ask, can the dialectic as developed by Hegel be applied to a context of simultaneity? Certainly, this seems possible if the organic unity imagined is that of the interpersonal dialog as opposed to long process of "progress." Foucault's heterotopia emerges as a particularly promising instance of a momentary instance of the dialectic in action. Here, truth is located interpersonally, held into place through the negotiations of language, in which the minute turns of the conversation shift meaning over from incomprehensibility to the furtive, contingent moments of communication. To answer my question, we can view the dialectic as a set when it reaches a point of singularity, where an event brings about a social and individual shift in consciousness. The closest we can come to simultaneity in this process is only when it functions systematically, as a set whose rules can be articulated within the defined constraints of its domain.

Ultimately, does it matter from an ontological perspective that the domain of discourse occurs within the boundaries of a long arc of historical time or an abbreviated one? Is the issue the interval within which the system processes information or is the issue the means by which systems process information? To reflect on the effects of processing speed, imagine the game of *Risk*. Played on a board with dice, it is a game that can easily last several hours. Players roll dice, argue with one another, take trips to the restroom, but the objective of the game itself is always to conquer the world. Early electronic versions of the game significantly sped up key aspects of play, most notably the rate at which combat is resolved, dead pieces are removed from play, and cards are cashed in for more pieces. Also, cheating and error are significantly more difficult in this iteration of the game. As processors speed up, these actions speed up significantly, such that an old digital version of *Risk* can run at speeds that exceed perception. And, with face-to-face interaction limited by the interface, table talk is further limited. Yet, the basic objective remains essentially the same: take over the world. Viewed from this perspective, the basic rules of the game of *Risk* and the objectives of play remain more or less the same, but on the computer, the five hour board game can easily be played in an hour. And, if you play against a computerized opponent, this play time can be compressed even further. Within this framework of interactions, speed itself makes no alteration to the game whatsoever, unless, of course, a key feature of the game is the relationship of the human player to the game as a discrete domain of interaction, an object consisting of many little pieces that follow many rules in pursuit of a particular end. With speed it is possible to care less about the game, to suffer the loss of the illusion of the game's relevance, to weaken the immersion, and to eventually erase its pleasure.

Thus, I argue, that to understand the meaning of any process, the projection of a hypothetical subjective externality to the system matters (In other words, subjectivity produces criticism and is produced by

it). The dialectical view is less a progression through sequentially interrelated phenomena, than it is a commitment to a critical relationship to systems regardless of their interval. Just as one can easily perceive the vast difference between distinct iterations of the same game whose rules and objectives remain the same, one can affirm that the human subject itself can always potentially exist as the site of the critical encounter, when one directs consciousness to seek the most subtle relative differentials between the representations. The dialectical process is a simplification of this basic process of consciousness, and we map it onto illustrations that are obviously sequential, but the critical capacity could easily be mapped onto more subtle sequentialities, networked causes, distributed effects, and nearly simultaneous interactivity. What is needed is not a new critical faculty, but critical tools and techniques which can effectively account for differentials that occur beyond the limits of our perception. We must acquire telephoto lenses, wide angle views, slow motion techniques, freeze frames, and other ways to comprehend fast interactions, wide sweeps of behavior, gentle modulations of thought and action.

But, at the same time as we deploy new tools and methods, we must not mistake these tools and methods for subjects themselves, for the basic goal remains the same: to know what it is that is happening when something happens. The critical faculty itself, while significantly altered in its form by the new terrain, cannot be altered in its function without ceasing to be criticism. In other words, against the backdrop of material and cultural changes (both microscopic changes to the object of criticism and macroscopic changes to the system within which objects are situated), we must begin first by imagining the very potential of the truth procedure itself, the hypothetical perception of rupture. For, though we are always first situated within a milieu which seems to define itself through the consistencies of its domain, we also know that it is this very situated character of subjectivity that desires to be otherwise and elsewhere, whether we seek to be a few inches over or a few seconds sooner or later, we have motive to move, to form, to alter, to explore. This very kindling of desire is what removes us from the present moment and places us into the slipstream of historical and speculative thinking, of memory and anticipation, is the selfsame capacity that at the more abstract level enables us to imagine sudden tectonic shifts or to witness glacial changes. Those revolutions of thought which alter the very ground rules that frame what we see begin as critical stances, as hypothetical alternate subject positions that challenge the ones that we presently occupy. Criticism must begin with a commitment to what it is: A position, enmeshed in the social web, but never simply constituted by it. To put it more bluntly, criticism might be the decision to be something more than nothing, to step out of epiphenomenal existence, to struggle against instrumentality.

While poststructuralism has rendered it difficult for subjects to imagine discrete, defined roles in discursive projects, the projection of such roles is necessary if we wish to engage in critical practices. This is not to pronounce that I am a “critic,” and therefore will cease to be a “reader” or “writer.” Rather, it is to say that in a time when crowd-sourced approaches, fan-based scholarship, and the general spirit of open access have revealed the critical value of readerly practices, we must then accept the notion that alterations to these practices matter. At a time when networks, technology, and participatory media trends have likewise removed the critical barriers to aesthetic expression, we must accept the notion that writing has also been fundamentally altered. Rather than permit criticism to be subsumed into expressive and interpretive practices, the task before the critic is to imagine criticism that can identify in these shifts a fundamental change in the relationship between reader and writer via text. We learn nothing beyond what we already know if we overlook the systemic relation between writer-text-reader (or producer-commodity-consumer, programmer-software-user, architect-building-occupant, teller-story-listener, or really any mediated relationship).

To truly apprehend the nature of the dialectic of reader and writer held together by the thread of the text, there must be a clearly delineated third position, that which is neither reader nor writer, though one might at times be one, both, or neither. Rather than define the critic as a special class of person, it is better to identify the critical faculty as a distinctive subject position, a way of viewing the text and how it functions socially as a nexus of interaction between readers and writers.

The problem of speed, though it upends the vertical progression of past regimes of production and reception, is not in itself a problem for criticism. There are still readers and there are still writers and they still interact through the text. The difference is that these particular subject positions are not so easily isolated, not easily localized on a particular historical individual or archival document. We don't necessarily need a stable sustained form like the novel or the Gothic to understand the significance of Electronic Literature more deeply (though such consistencies, where they are perceptible, provide excellent case studies), what we need is a critical exploration of the plane of consistency itself (in this case, it is that of technological change and social adaptation). What Derrida did for words, we must do for the interface, the platform, the logic of new media itself. But we cannot simply argue against the aura of stability associated with words, we must turn to the aura of currency, of the presumed veracity of change, of the upgrade, of the improvement, of the debugged. The promise of newness is that which we have come to trust. A rigorous discussion of this trajectory is among the most pressing critical projects facing us today: What are the poetics of innovation? How does it function grammatically? How does the poet play with this language? What are the social, ethical, philosophical implications of this presumed foundation of cultural existence. Whereas past critics may have had the time and luxury to mistake their acts of reading or writing with criticism, losing sight of the function of the text within culture, we have the luxury of living at a time when we are seeing a radical shift in the function of the text itself. The question is whether or not we will do it. Or if we will simply watch the relationships between readers and texts change without thinking critically about what these changes mean, what changes we'd prefer, what changes we'd sooner avoid. In effect, it requires a critical commitment, not to what we will conclude that the text means, but to a process of criticism that is preoccupied with care, that is "interested" in the very hope that culture might truly be determined through a disinterested process of seeking what's best for human culture, rather than being determined by the tremendous social forces that have emerged as a default consequence of ademocratic processes of free market ideology. We must, as *Ars Industrialis* suggest in their 2010 "Manifesto," "struggle against carelessness [*incurie*], against the destruction of attention." [5] Such literary criticism must attend to that which is not immediately understood, but which holds power in the realm of expression, which animates the text, which is written, hard to notice, but nevertheless true.

In practical terms, as it pertains to the *Electronic Literature Directory*, there are two possibilities relating to the twofold process of the ELD's editorial protocols. On one level, it is a rather mundane, but necessary, meeting place for readers, writers, and works. The entries themselves really and truly do tend towards mere readerly descriptions. [6]

The second possibility, and this is one is highly contingent, is that database projects like the *ELD* may serve as a nexus for precisely the cultivation of care and attention in service of the social as the next logical step towards a criticism that is, to quote Matthew Arnold, "sincere, simple, flexible, ardent, ever widening its knowledge." In creating a common space, a public sphere for "electronic literature" that is open to all, we might inspire and cultivate a critical practice which is aware of the changing dimensions of the text vis-à-vis the discourse that takes place on our pages. What we lack in the slow deployment of verticality, we might gain in horizontality. If we grow large enough, not simply as a matter of quantity, but large enough in the depths of our social consciousness, we might take this broad horizon of literary

discourse and, in the crucible or speed, pressure, and the needs of the moment, distill a sense of just what these changes mean for criticism.

UNMEDIATED EXPERIENCE? RE-MEDIATING PHENOMENOLOGICAL APPROACHES

Christiane Heibach

The paper discusses the theoretical tension between the desire for unmediated experience formulated in some contemporary media philosophical approaches, and the evidence, that our experience is inherently related and maybe also formed by media. How can this tension be solved? And what are the necessary theoretical approaches for a model of perception that meets the demands of our multisensory and multimedia environment?

Processes of perception / Theories	Traditional Philosophy (Body/Mind-Dualism)	Phenomenology	Anthropology/ Sociology	Cognitive Sciences	Media Theory
Sensory perception	<i>Neutral standardized process with limited contribution to intellectual insight</i> <i>Dominance of the visual as the most distant and therefore analytical sense</i>	<i>Basis for our relation to the world – no neutral sensory input, because those data are always already interpreted</i> <i>Dominance of the visual as paradigmatic sense</i>	<i>Models of sensory perception are culturally different and depending on processes of communication within social communities</i> <i>Culturally different hierarchies of the senses</i>	<i>Biological and chemical processes of data processing in the brain based on standardized models → topography of the brain's sensory areas</i> <i>Focus on visual perception (Semir Zeki)</i>	<i>Sensory input is formed by the cultural dominating media → co-evolution between media and perception (Marshall McLuhan)</i> <i>Dominance of the audio-visual</i>
Intellectual	<i>Pure Insight/cognition comes from a priori knowledge that is solely preformed in the brain (Descartes, Kant)</i> <i>→ guarantee of rational and comprehensive realization of the world outside</i>	<i>Principle of Intentionality (Husserl, Heidegger, Merleau-Ponty)</i> <i>→ Objects are part of us as they exist only the way they are given to our perception – no strict subject-object-division</i>	<i>Dominance of the observer-object-relation → distant analytical processes of insight (although critically reflected in models of participating observation in anthropology)</i>	<i>Consciousness as complex process of world construction in the brain</i> <i>→ the constructivist power of the brain to create its own world questions the subject-object-division</i>	<i>Standardized cultural techniques (reading, writing) are developed in co-evolution with the dominant media of a culture</i> <i>→ Intellectual processes are media-driven and not supercultural</i>
Emotional	<i>Excluded from the intellectual insight</i> <i>→ Kant puts emotions to the subjective side of the faculty of judgement, the aesthetic experience as like/dislike-reaction</i>	<i>The holistic psycho-physiological model of man (Merleau-Ponty, Schmitz) includes also emotional reactions on the perceived</i> <i>→ sensory perception and emotion are bound together</i>	<i>Reflection of different cultural and historical models of emotion (e.g. Norbert Elias), social meaning of emotions (e.g. Niklas Luhmann), but: sociology relies on concepts of rationality</i>	<i>Differentiation of emotion/feeling (Antonio Damasio), the first is 'natural', instinct-driven, the latter culturally formed → unity of mind and body, but: no concept of sensory perception</i>	<i>Media cause emotion and trigger emotion – but:</i> <i>Focus on film/literature</i> <i>→ no reflection on the cultural formation of emotions</i>
(Re-)Action	<i>Action is not part of traditional philosophical reflection – unless it is mental action → e.g. processes of decision (ethics)</i>	<i>No model of action – the concept of intentionality might be seen as a kind of proposal but resembles more the mental models of traditional philosophy</i>	<i>Models of action mostly concerning rituals or standardized social action driven by rational motives and excluding emotion and subconscious processes</i>	<i>Action as result of complex neurological processes triggered e.g. by hormones, but also by other cognitive processes → basic emotions in oscillation with rational thinking</i>	<i>Different concepts of action:</i> <i>- interacting with technical media</i> <i>- acting within media (e.g. strategies of self-marketing)</i>

During the last few years – and very obvious for example in some panels of last year’s ISEA – one can observe a somehow paradox tendency: Theorists coming from the philosophy of media tend to dream of a sort of “unmediated experience” as the Canadian philosopher Brian Massumi called it, [1] and media artist and theorist Christopher Salter spoke of “felt meaning” as a form of insight which lies beyond the traditional concept of language driven consciousness. [2] Another example: Mark Hansen, author of the book “New Philosophy for New Media”, [3] re-animates a concept coined by Henri Bergson in the 19th century: the bodily affection which Hansen describes as holistic psycho-physical perception mode and confronts with contemporary audio-visual media. In his explicit concentration on the perceiver Hansen neglects the anthropological dimension of technical media which Marshall McLuhan had pointed out: that human perception has always developed in co-evolution with a culture’s preferred media. Furthermore, Hansen’s (and the Bergsonian) concept of “bodily affection” remains rather vague, just like the other concepts of an unmediated, embodied experience: Mainly they don’t distinguish between the different sensual perception modes – the body appears as a homogenous whole that is constructing its own experience of the world, and they assume that there could be a primordial experience without any preformation by nature or culture.

This longing for an unmediated experience which is based on an unspecified unity between body, mind and environment refers to phenomenological approaches in philosophy, which developed at the beginning of the 20th century: As already mentioned, Mark Hansen refers to Henri Bergson, who had significant influence on the founder of Phenomenology, Edmund Husserl, and later also on Maurice Merleau-Ponty; Brian Massumi in turn refers to 19th century psychologist and philosopher William James, who on his part influenced Husserl and Deleuze. James introduced the concept of “pure experience,” [4] an experience which lies before any subject-object division and – this is the logical consequence – seems to be pre-medial; a non-mediated physico-emotional way of experiencing the world before it becomes a separate part of oneself.

Phenomenology developed during a time where daily life in European countries at the beginning of the 20th century underwent deep changes: There had been an accumulation of technical developments like the steam engine, electricity and the new media photography and film – all significantly changing our

perception modes. Phenomenological approaches like those of Edmund Husserl (1913), [5] Helmuth Plessner (1923) [6] and later Maurice Merleau-Ponty (1945) [7] opposed to the traditional epistemologies that had emphasized intellectual insight as independent from the body and equated sensory perception with visual perception. The changing epistemological environment proved the contrary – and the traditional dualistic mind-body separation seemed to come to its limits in facing the acceleration and multisensory appeal of the electrified cities and technologized perception modes.

It also might be no coincidence that the revival of phenomenological approaches is correlated with the diversification of our self-experience we currently undergo. The paradox, that theorists and practitioners who have been moving within the universe of new digital media, now call for a pre-conscious, non-intellectual, unmediated and primarily physical and emotional experience of the world, might even be a logical consequence facing a world that becomes more and more complex and where we are confronted with a multimedia environment that challenges our current models of perception and the dominance of intellectual insight.

In our every-day life we have to play multiple roles in different medial environments: communicating with friends in social networks like facebook, managing our daily real life environment, proving our intellectual capacities in our jobs, being active in our leisure time with sports, cultural events etc. All this also means managing multiple media like TV, Radio and Internet, but also diverse sensory, affective and intellectual inputs of places that are part of our daily life: be it the sensory appeal of shopping malls or wellness environments or cultural sites. The longing for an unmediated experience might be a logical reaction to this intersensory and intermedia overload. But is the current tendency to turn away from the media and praise an unspecific holistic bodily experience that ignores media theoretical acquirements really a solution for the problem that we need a more complex model of perception? I doubt this – and would like to illustrate the demands of a model that reconciles concepts of embodiment with media theory in turning to an example of a work of art:

In 2001 the Mexican artist Teresa Margolles presented her work “Vaporización” – “Vaporization” in Berlin. It seemed to be a quite simple work: The visitors entered a room which was filled with a fog-like substance. Their sight was limited, but they felt the humidity of the fog on their skin and of course inhaled it by normal breathing.

This was all – so what the visitors experienced was first of all the atmosphere of a quite dark and foggy room full of a humidity that not only enwrapped their bodies, but which also became part of their organism through the pores of their skins and through breathing in. Finally the visitors were informed that the humid fog consisted of water that was used to wash the corpses in the Mexico City morgue. Although it had been disinfected the experience of breathing water that had become part of nameless corpses and that now became part of the own body has something deeply frightening and might in most cases have caused the emotional reaction of deep disgust, and probably also the feeling of somehow being physically misused by the artist.

This becomes very obvious in a variation of the concept, a work called “In the air” from 2003 (En el Aire). I would like to quote a description I found in the World Wide Web (published under the author’s name or pseudonym “Lolla Moon”):

“In the museum’s soaring hall children play under bubbles that come from Teresa Margolles’ piece En el Aire (In the Aire 2003). Running, laughing, catching, they are fascinated by the glistening, delicate forms that float down from the ceiling and break up on their skin. A common motif in art history, the bubble

has long been used as a memento mori, a reminder of the transitory nature of life. The children's parents, meanwhile, studiously read the captions. Suddenly, with a look of disgust, they come and steer their offspring away. The moment of naïve pleasure turns into one of knowing repulsion: they have learned that the water comes from the Mexico City morgue, used to wash corpses before an autopsy. It's unimportant that the water is disinfected; the stigma of death turns the beautiful into the horrific." [8]

This example and the description show a further dimension of Margolles' two works: The visitor is not only concerned with her own body and the proprioception in realizing what has touched and somehow invaded her body, but also with the instinctive impulse of protecting her children from being confronted with death, and probably with the body of dead people one had not even known. The intimacy of getting touched by someone is combined with the covering-up of death in our Western cultures. So Margolles' work breaks multiple taboos:

- First of all she minimizes the distance between the material she uses for the installation and the visitor. The material finds its way into the organism of the visitor and somehow melts with parts of her because the perception organs are not the distant senses ear and eye but the skin and the nose, sense-organs which have long been aesthetically ignored and therefore somehow lack any aesthetic tradition and education. So the medium chosen (the fog), and the triggered sense organs are quite unusual and challenge our standardized perception habits – which is the epistemological dimension of the work.
- Secondly she confronts the visitor with her (the visitor's) own body and her relation to other - dead - bodies, which rises ethical questions. At least it confronts us with our culturally influenced attitude towards death and towards anonymous corpses from a country where for many people survival is a challenge which has to be faced daily anew in drug war and crime – this is the intellectual and cultural dimension.
- Both together – the transgression of perception habits and cultural taboos – lead to a deep psychophysical experience that shows that intersensory perception, intellectual and cultural knowledge, emotion (disgust) and feeling (horror), and finally also action (taking away the children) are inherently bound together.

This example is so interesting because it ignores one unwritten law of art: to leave the recipients in a state of autonomy where they can decide whether they want to participate or to draw back and stay an observer. This choice is essential to keep the playfulness of art, even in borderline cases. Just to name one example: The Austrian Artist Hermann Nitsch organizes every year what he calls "Orgien-Mysterien-Theater" ("bacchanal-mystery-theatre") where a lot of animal blood and bowels are spread among the participants. Nevertheless it is left up to the audience whether it wants to participate or not, and at least everyone knows in advance what expects her/him when visiting such an event. Margolles instead confronts us with a part of our real life we normally tend to push aside in minimizing the distance art normally builds up between itself and the spectator/visitor: She uses a medium, water, which stands for cleanliness and purity, and brings this together with the visitor's body as medium so that both merge through breathing in a process which happens beyond the visitor's control.

In table 1, which of course is not exhaustive but rather a scheme, I tried to sum up the main theses of different theories dealing with the problem of perception and experience from different perspectives.

The leading question for this overview is the topical demand for a combination of intersensorial and intermedia theories. The table will show that in most cases media are neglected – and with this the social and cultural aspects of perception/experience.

This overview refers to approaches of very different disciplines and examines how they treat the processes which I consider to be decisive for the complexity of experience: Multi- or intersensory perception, intellectual and emotional processes as well as concepts of action. It is obvious that every approach has its blind spots – consequently setting up a model for ‘experience’ is an inherent interdisciplinary task. And it shows that nearly all approaches lack a notion of media, in first place Phenomenology which claims to explain the processes of every-day-experience – but its approaches prove to be incomplete without considering the multiple impacts of natural and technical media. I doubt the existence of an unmediated experience, although a pre-conscious “feeling” surely belongs to what we call experience. But, as Helmuth Plessner and Maurice Merleau-Ponty point out, there is no sensory perception – and, I would add, no unmediated experience – without interpretation: even if our interpretative mechanisms are based on biological and chemical processes in the brain, they are also culturally and socially induced. In concentrating so much on technical media we tend to forget that our experiencing senses and our feeling body are media as well, as Margolles’ piece “Vaporización” shows. Without our culturally induced neglect of death, without our instinct-driven, but also culturally formed scepticism that tells us to keep distance from everything which does not belong to our own bodies, the effect of “Vaporización” would not be this provoking as it has been proven to be. Margolles uses the human body as medium: first, the particles of the corpses are merged with the water so that they are transformed, then the bodies of the visitors become media in absorbing and again transforming the corpses’ cleaning water. In this constellation the visitor’s bodies are object and subject at the same time.

I want close this contribution with another example: Anish Kapoor was the invited artist for this year’s Monumenta in Paris. For the Grand Palais, a very light and beautiful architectural construction, he created a sculpture he called “Leviathan”:

“Leviathan” is the name of a beast which was created by God in order to reign over the sea. It was invincible and could only be defeated by God. According to the Babylonian Talmud Leviathan (who exists in Christian and Jewish tradition) studies the Tora, judges and nourishes the world and then plays with the ships on the sea. So Leviathan has become the synonym for a monster that causes chaos and is unrulable. Kapoor’s “Leviathan” does not move, but it swallows everyone who comes to visit: thus it has a monstrous inner and outer appearance (as the images show), but both work very differently: Within the monument one feels as if being swallowed by a whale like the biblical Jonah. The dimmed red light (which has a natural source from the glass roof of the Grand Palais, filtered by the red synthetic skin), the sticky air, the damped sound and the very round shape that branches into cave-like bulges evokes associations of being in the stomach or bowel of a beast or in an uterus (but without the protected feeling one should have there). Stepping outside the impression is completely different: One sees “Leviathan” as a sculpture from a distance, the light is natural again, the air fresh, the sounds have regained their resonance – it is an object again and can be treated as such.

“Leviathan” offers us at least two perspectives: One is unusual and challenges our sensory perception, our psychophysical proprioception, and our intellectual ability of evoking associations, the other offers us the far more familiar perspective on an object which can be experienced mainly visually as a sculpture (but also in touching its skin) and lets us feel much more comfortable because we can remain in our culturally acquired habits of perceiving art. Kapoor thus oscillates between the creation of an interior media arrangement causing an experience that differs from our everyday perception on the one hand,

on the other he creates an outside space that allows us to regain our usual perception modes – “Leviathan” changes between unfamiliar and familiar intersensorial and psycho-physical forms of experience. This indeed seems to me to be one of the most valuable qualities of contemporary (inter-)art forms and it makes obvious that the newly evolving desire for unmediated experience is somehow romantic, but not realistic and not necessary at all if a complex model of experience is adopted.

So consequently the complexity of multi- or intersensory experience is not adequately modelled in adopting only one concept, be it

- processing sensory data, even if multisensory perception is considered,

or be it

- experiencing a pre-conscious holistic bodily affection with its related emotional processes,

or be it

- biologically explainable cognitive processes

or be it

- ‘pure’ intellectual insight.

All of these approaches are complementary, and they are always related to individual and cultural experiences (emotions, knowledge, habits) and media, which means natural and technical media alike. The examples should have made clear that there might be no unmediated experience, and that intense experience is a complex combination of multiple factors that can only be treated in an interdisciplinary effort.

INVESTIGATING INTERACTIVE BEAUTY – A RESEARCH-ART INSTALLATION

Falk Heinrich

My paper presents and discusses my academic-artistic installation *Investigating Interactive Beauty (IIB)* being part of a theoretical investigation of the notion of beauty in interactive art. *IIB* is on the one hand an art installation and on the other hand an experiment that allows for collection of user opinions and experiences. Interviews and questionnaires, one prior and one, seek to collect opinions on the notion of interactive beauty.

Fig 1. *Investigating Interactive Beauty* – a research-art installation 2011

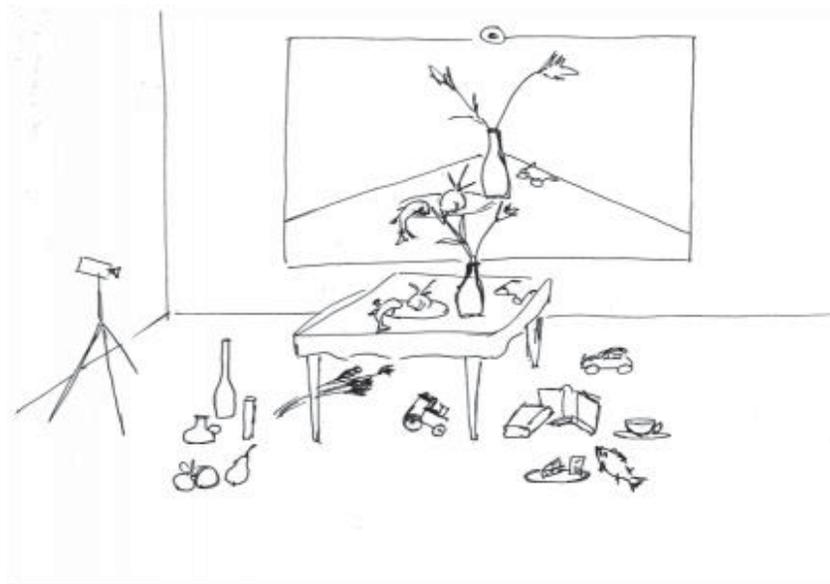

Fig 2. *Sketch of Investigating Interactive Beauty*, 2011

This is a presentation of the academic-artistic installation *Investigating Interactive Beauty*, preceded by a short introduction to the overall research project *Interactive Beauty*. My field of investigation is the notion of beauty in interactive art.

In academic literature, beauty is often described as an aesthetic judgment of an artefact or an object. It is generally seen as a sentiment of positive arousal. During modernity, art has been positioning the onlooker at a 'distance' allowing for a sublimation of the onlookers' immediate physiological reaction to the piece of art. The distinction between reality and fiction is one prominent example of this distance. Art works are to be contemplated. This gave rise to a distinct notion of beauty that is tight to 'emotional reflection' underpinned by the purposelessness of art (Kant). But different philosophers have different views on, whether beauty is an immediate emotional reaction or whether interpretative reflectivity plays a part in the sentiment of beauty. Beauty is generally seen as a positive experience; it is nevertheless founded on a perceptual distinction between beauty and ugliness. During the century of modern art, both its artistic and academic proponents, reject the validity of beauty for art making. Yet, there are also other voices stressing the historical changeability of the notion of beauty. For example, Roger Fry's *Vision and Design* (1961) asserts that the initial ugliness of modern art already has become beautiful since art changes its notion of beauty. The sentiment of beauty in modern art shifts from being an exclusively aesthetic judgement to be interplay between conceptual and 'purely' aesthetic dimensions.

The following thoughts and the conducted experiment is based on the belief that the sensation of beauty is an emotional reaction framed and generated by cultural and conceptual values; there are no essential and normative requisites for beauty. Nevertheless, I do not see beauty as an exclusive driving power for art; our notion of beauty today is highly dependent on other cultural developments like media technology and media artefacts (video games, interactive TV, computer applications and apps).

Foundational thesis

The shifting notions of beauty from the Renaissance up to modern and post-modern art rely on a distant positioning of the onlooker in front of the artwork. There have been many efforts to make the audience a part of the artwork, like for example installation art, performance art, and recently interactive art. In interactive art the onlooker has finally become a participant physically acting and reacting within the timely and spatial framework of an interactive art piece. Consequently, there is a need for a differentiated notion of beauty that takes into account the beauty of doing, (re-)acting, performing, and creating within a conceptually confined space of possible interactions. My hypothesis is such: the experience of beauty in interactive and performative art pieces has changed (or is in the process of transformation) from being an act of contemplation to (1) an intrinsic sentiment of interaction proper and (2) a reflective post-actional sentiment.

My investigation is mainly a theoretical one relying on philosophical inquiries, trying to answer a whole array of questions: Is the notion of interactive beauty an indication for a changed socio-cultural context or is it a phenomenon exclusively bound to interactive art? Can we trace a changed notion of beauty taking into account historic philosophical theories on beauty from the Greek Classics to modernism and post-modernism? The notion and sentiment of beauty is without doubt context dependent rendering different dimensions of beauty, what is then the relationship between let's say design and art, or the blooming beauty industry and interactive art? My hypothesis has its roots within the domain of art and art experience being thus a research question within the domain of aesthetics and art theory, but do other scientific disciplines have different notions of beauty - I here think very much of design theory and

marketing, psychology and neuroaesthetics - and how can these disciplines contribute to my investigation?

Artistic Investigation as academic method

Despite the overall theoretical modus of my investigation, I nevertheless want to describe an empirical experiment that tries to tap into the interactive art participants' opinions on the question of beauty. Since the question of beauty in modernity and post-modernity is considered to be a subjective judgment and not the result of a normative doxa, a phenomenological method of investigation is the only appropriate one. The overall method of my research is a circular (or cybernetic) process, consisting of firstly theory formation as a discursive process that questions and re-describes already existing theories on beauty, and secondly the validation of my theoretical findings by means of observation and analysis of interactive artefacts by various artists as well as own artistic experiences. It has to be emphasised that most interactive art works do not specifically investigate beauty, yet it is my conviction, that all operate with the sentiment of beauty (or ugliness). This cybernetic process takes as its starting point my own experiences as a participant of numerous interactive artefacts as well as my experiences as a maker of such artefacts serving thus as a lived and internalised background for my theoretical research. In this I follow a well-established, discursive, hermeneutical research methodology, mainly found in the humanities.

In addition to my own experiences, I decided to design an experimental setting in form of an interactive art installation. The objective of this experiment is to generate empirical user data, through, firstly participant observations, and secondly interviews. It is my hope that the results will broaden my own understanding of the function of beauty in interactive art. Contrary to the modus of experiments prevalent in the natural sciences, the goal of my experiment is not to verify or falsify a hypothesis, but rather to create a framework for concrete interaction, which allows me to further my own understanding.

The interactive research-art installation should therefore encompass both an artistic experience of a kind and a reflective perspective on the nature of beauty in interactive art. In other words, the research-art installation aims at an experience of interaction that thematizes and discusses the notion of beauty. The objective cannot be to design beautiful interactions (because beauty is a subjective sentiment), but to design an installation that contributes to the discussion of the notion of beauty in interactive art.

Designing an interactive research-art installation gives rise to many questions and challenges. One of the foundational questions is, whether it is possible to design an installation that serves art and academic research alike. As such, my experiment forms part of an already existing, but still incipient academic praxis, where artistic methodologies are used to generate a field for observation that can render different understandings of a chosen subjects (e.g. Leavy, 2008; Kaplan 1996). Artistic processes rely firstly on certain art genres and secondly are scientifically idiosyncratic explorations without a fixed goal in terms of solutions to predefined problems. Academic humanistic research on the other hand depends on a thesis and a method that generates answers. By applying an artistic method, I therefore cannot hope for definite answers, but expectantly for rather vague indicia showing general tendencies, and new valuable questions to be answered. My investigation reckons the dependency on art genre and general cultural developments. In that, it differs from for example the neuro-aesthetic (e.g. Zeki 1999, 2004; Ramachandran 1999; Turner 2006) and psychological approaches (e.g. Arnheim 1969; Boselie, F., & Leeuwenberg, E., 1985), which aim at finding generic perception principles for the sensation of beauty.

The design of the interactive research-art installation *Investigating Interactive Beauty (I-I-Beauty)*

The basic idea of the experimental installation is the seemingly contradictory notions of contemplative and interactive beauty. In the research art installation, the former is represented by the static representational genre of *still life*. The latter by the very artistic act of creating and composing *still life* set-ups. In that I am following one kind of interactive art, where the art piece offers and uses the participants' poetic (creative) impetus. The installation will give the participants the opportunity to create a physical model of a *still life* and see the photographic result of his/her arrangement real time.

The installation space is a square space. A table with covered white cloth is standing in the middle. Upon this table, the participant can put and arrange various objects found in many still life paintings: vases, flowers, food, dead animals, etc. The objects are scattered on the floor around the table. The whole scene emulates our romantic picture of an artist's studio. The participant can use these objects in order to create their personal still life arrangement on the table. The participant can illuminate the scene with a simple set of lighting devices (front and side lights). The camera, constantly recording the still life, is positioned in a 45-degree angle in front of the table. Behind the table, a projection shows the video picture of the table and the arranged still life.

But the picture is not a photorealistic depiction of the material still life arrangement; it shows a digitally manipulated picture. The degree and kind of modification depends on the amount and kind of the participant's physical action around and on the table. An infrared camera and various algorithms track the participant and extract a data-description of his/her movements and motion in space. These data are used to digitally manipulate the video image.

The modification of the video picture is inspired by some exponents of art history's development from representational art to various kinds of motion abstraction (Balla, Boccioni, M. Duchamps, Muybridge) and the aesthetics of digital image manipulation. The modification process is triggered and computed by the data of various movement parameters (especially the accumulative quantity of changed pixel values). Despite of the fact that motion results in modification of the digital image and non-motion in a slow transformation back to a photo-realistic, static representation, the detailed algorithmic logic is not completely transparent. The transformational logic should be a part of a semi-enigmatic process controlled by the algorithmic system.

The experiment

The experiment begins with a short initial introduction to the overall objective, namely the investigation of interactive beauty and to the aesthetics of the chosen genre (still life). The research-art experiment is framed by an informal interview structured by questions.

1. The first part of the experiment consists of three initial questions:

Could you briefly describe your sensation of beauty?

How would you describe beauty in art?

Have you ever experienced beauty in interactive art (as a participant or as an onlooker)?

The pre-interaction questions seek to get information about the participants' general notion of beauty and specific notion of artistic.

2. The second part consists of the interactive experience. The participant is supposed to create a still life out of the available objects. S/he can decide to finish the experiment by clapping the hands, which makes the system save a file of the digitally manipulated picture.

3. After the short interactive experience, I pose more guiding questions:

Can you describe the relationship between the intended beauty of the tableau and the experience of arranging the tableau?

What elicits satisfaction and reward in the process of composing the still life?

Can you describe the difference between the unmediated and the digitally manipulated of picture?

The purpose of these questions is solely to propel a general discussion on the notion and function of beauty in interactive art.

Preliminary results

At the present moment, the research installation has been tested (both the digital system, the set up and the questions for the interview), but no real research experiment has been conducted. The test interviewees were students of the educational program Art and Technology at Aalborg University. The purpose of the tests was to examine the validity of the questions asked, the functionality of the artistic research installation, and the discovery of unintended aspects. In the following I am presenting the main points made integrating the interviewees' wording into my interpretation of it.

The first interview did reveal that the notion of beauty is associated with "attraction", "pleasing objects", "kindness" and the "simplicity and purity" of the object eliciting the urge to be "near and observe" the objects. Beauty is a kind of "positive" holistic conclusion made by audience, beauty sets "a period!". Beauty in art is associated with both the sensuous aspects ("awareness") but also with the conceptual aspects. A "great and strong artistic idea" with a vital "message" is beautiful. In regard to interactive art, the interviewees pointed out that a requisite for the sentiment of beauty is a "clear understanding" of the interaction mechanisms. A beautiful interactive art piece "talks to and attracts" the participant. One interviewee asserts that beautiful interactive art pieces must make sense also without the user participation, which I interpret as the clear conveyance of the conceptual dimension of an artefact.

The second part of the interview after the interviewees' experiences with the interactive still life installation revealed, that the interviewee generally like to interact and having the possibility to create and arrange their own still life (which of course is not surprising, since they all are art and technology students). They felt good as a participant being able to choose certain objects and to disregard other in the process of arranging the still life. They all sought to express a personal idea about the intended still life. Some of them chose the objects due to their symbolic value. They acknowledged that their personal vision is heavily influenced by genre paradigms and conventions of still life.

There seems to be an unintended gap (for one interviewee even an incompatibility) between the arrangements on the table and the digital representation of the tableau. It seems that the experiment deals with two different forms of interaction, a mediated and an unmediated one. This led me to a bipartition of the second part of the experiment. In the future, the participants will be asked to focus on the arrangement of the still life (the video picture will show the tableau non-manipulated), and, in a second round, to focus on the digitally modified picture in order to elaborate on the different mediation modes.

Discussion

The experiment needs of course to be conducted for real with a demographic variety of persons interested in interactive art. This paper deals primarily with methodological questions in regard to the design of a research-art experiment as a qualitative method.

I could simply have conducted interviews with audiences of relevant interactive art exhibitions. But designing an experimental research-art installation fulfils at least one further goal apart from the collection of user experiences and opinions. The process of designing an experiment with an academic purpose (in my case the generation of user experiences of the function and sentiment of beauty in interactive art) reveals much of the nature of my research subject. For example, the notion of beauty is extremely domain-dependent; there no longer exists a general notion as in Schiller's era, where beauty indicated a unified moral and aesthetic refinement. Today's beauty is not able to defy the experienced fragmentation of life, revealing the obvious subjective quality of beauty.

One preliminary result of the test scenario seems to show that beauty in interactive art is not exclusively bound to the individual experience of interaction. The interviewees' experiences were described as funny, interesting, and rewarding since the participants are given the possibility to tell their own stories and preferences (through the choice and arrangement of still life objects). Yet, the experience of beauty seems to necessitate the objectification and extrapolation of interactive experiences into the realisation of the artefact's conceptual dimensions. The test persons seem to merge and align their existing contemplative notion of beauty in the arts with their performative acts during interactions.

FUZZY PRECINCTS AND BLEEDING EDGES: FEMINIST THEORY AND THE STUDY OF VIRTUAL-MATERIALITY

Lynne Heller

Following a trajectory of the virtual/material dichotomy as it stems from a classicist position of a mind/body and male/female split, I propose feminist theory as a potent tool to effectively analyze the artistic implications of virtual materiality. Obfuscation, bedlam, redundancy – these qualities, redolent of humanity, are typically considered the antitheses of insight. The chaotic can be an impetus for relinquishing conceits of specialization.

Whatever the breaks and ruptures, only continuous variation brings forth this virtual line, this virtual continuum of life, "the essential element of the real beneath the everyday."
Gilles Deleuze and Félix Guattari [1]

As an artist working in diverse media – performative new media interaction, digitally collaged graphic novels, and hybrid reality sculptural installation, I have had the opportunity to experience a breadth of contemporary creative practice, unfettered by traditional labels.

My art reflects my fascination with the yo-yo play between the two ends of a spectrum, at one end the virtual, on the other, the material. Integrating perceived oppositions has been an ongoing creative concentration for me. By essentially not 'fitting in' to any particular artistic convention, I have been free to create my own structures which inevitably pose questions of differentiation. If the two extremes, virtual and material constructs, meet and interweave on an intimate stratum, then how does one start to parse and separate them? Is it possible and / or desirable? When imagination and concrete details fuse at a molecular-like level, is it useful to consider these as separate parcels? Are packets of digital information virtual or real? Perhaps neither virtual / spirit or material / substance but simultaneously both, a unique process or matter that I will refer to throughout this paper as virtual-materiality. Analogous to light – an often invisible continuum that is defined only when it comes into contact with something else, creating colour and shadow. It is not defined by established theoretical frameworks, but through the interpretation of its internal limitations. [2]

By way of example, in my piece *Dancing With Myself* (2009), a performative hybrid-reality installation, I explore virtual-materiality through dance. My avatar, Nar Duell, has been scripted to perform a choreography. In real time performance she moves in an immersive environment projected onto three walls. I

respond to Nar Duell, attempting to create a duet with her, thereby inverting the person / avatar paradigm, as Nar Duell controls me. Her world is expansive and infinite, whereas the real world space where I respond and dance, a white-walled gallery setting, is boxed in and confined: once again reversing the usual view of space through a computer screen. At the end of our performance, when she has either 'expired' or perhaps is 'just plumb tuckered out', I stroke Nar Duell's face. In reality, I am touching the cold hard surface of the gallery wall, nevertheless, the warm presence of projection and the intimacy of our interaction conjures up an all too posthuman relationship. [3] Through this caress, undeniably material things (human hand, painted drywall) become conflated with the agency that I have invested in my avatar. The action ceases to be touch of simple surfaces and strives to cross a divide. Unable to label this moment virtual or real, even digital or analogue, I can only think of it as quintessentially virtual-materiality. Nar Duell's exhaustion is clearly virtual and I am most decidedly material, but the act of touching my avatar transcends an understanding of those two states. Similarly, in another piece, *Pushing Art* (2010), I display a video projection of my hybrid-reality graphic novel in a real-life mobile rendition of a hot dog cart and newspaper stand – once again confounding boundaries. We are no longer dealing with differences but with a continuum that defies parsing.

The turning point of this argument depends on the idea of the agency of images, addressed by the theorist W.J.T. Mitchell in his seminal text *What do pictures want? the lives and loves of images*.

...the peculiar tendency of images to absorb and be absorbed by human subjects in processes that look suspiciously like those of living things. We have an incorrigible tendency to lapse into vitalistic and animistic ways of speaking when we talk about images. It's not just a question of their producing "imitation of life" (as the saying goes), but that the imitations seem to take on "lives of their own." [4]

The most basic of human interaction with objects, particularly images, causes us to necessarily invest them with spirit in order to understand, control and dominate the 'stuff' of our existence. From a simple photograph of a loved one to the complexity of a virtual alter-ego we must process what we are looking at through memory and emotion. When my avatar, Nar Duell had the misfortune of a corrupted database I had to come to terms with the zeros and ones of her being. For an entire week Nar Duell and I had to sustain the indignity of having her hair attached to her posterior as she inhabited her Second Life world. She slunk around assuming poses where other avatars would not view her backside and the offending tresses. Clearly, I was projecting my embarrassment as a human being on this animation, but her bizarre behaviour was real within the context I had created, and made for an entirely different art experience. As a result of the misplaced hair episode it became clear to me that Nar Duell was protesting the brunette hair I had bought her only an hour before the data corruption occurred. She is now, and for whatever future she has, decidedly blonde. What's a feminist to do?

Before discussing virtual-materiality any further, I would like to differentiate between the digital and the virtual. The digital is real enough on a computer chip, but because it exists initially as information only and must be transformed through on and off circuitry to be experienced, we perceive it to be virtual. Even though it must be processed to be experienced and not an obvious material manifestation, it is not virtual. Whereas the truly virtual resides only in our minds and through our imaginations. It is ironic given my interests in continuum that I am insisting on difference here but I think it is important to define the terms as they are often used interchangeably. Virtual-materiality is not necessarily digital-materiality. Digits are representations just as surely as is paint. However, the malleability of digital information and the variety of its manifestations does extend our ability to imagine 'bigger and better.' In my case it allows me to create Nar Duell and experience art and life right alongside her. The quirkiness of a populous, dumbed-down application such as Second Life along with the reality of bandwidth speeds and

other people's tastes means that it is an entirely unpredictable place. This eccentricity leads to the illusion of avatars in that environment possessing souls and controlling their own destinies – a virtual existence.

As I said in the beginning of this text, the genesis of this interest in virtual-materiality comes from my engagement with different media. That, in turn, is rooted in a deeper need to grapple with the contradictions of our humanity. There is a gap between our desires and reality which align with virtual / material extremes. By trying to define these edges I find myself in the wide swath of the middle, where the melding is impossible to untangle. If desire equals the virtual, where everything is possible, and reality, the material weighed down by the intractability of matter, then how do these extremes coalesce? Fortunately, art does not have to be an either / or proposition, it is both at once – a lenticular vision, beyond simple interpolation, that does not allow for the splitting of the atom.

This paradox, desire versus reality, is threatened to be rendered mute by contemporary consumerist ideology, and is echoed in pop cultural priorities. I look to pop culture as a marker to test my assumptions about yearning and that which is 'in your face' real. The drive to conflate those extremes, which I align with the virtual and the material, is a current obsession. For instance, three dimensional film techniques attempt to make a screen-based art form increasingly immersive and tangible. On the other hand, many material based artists, entertainers and marketers are using the advantages of digitally generated or transfigured materials and processes to invest the inert with intelligence. Of particular interest are technologies such as motion capture and mobile devices that allow intersections of real and digital immersion, crossing over into virtuality. An example of this is the mobile smart phone that allows razor sharpened marketing intelligence to guide the user into real world / virtual seamless consumer experiences. The interest in the public sphere is informing and compelling. When the difference between desire and commodity is supposedly erased, we can have everything we want and like everything we have. Or – so the story goes – this perpetuated fantasy is the bedrock of consumerism. However, it is an itch that gets worse with scratching. This presumably seamless virtual-materiality highlights the contradiction of the continuum. Even though we cannot dissect virtual-materiality we still know the two extremes. Capable of a double consciousness, we sense difference and conflation simultaneously. We believe desire and object to be the same thing. Obtaining something will soothe a yearning, but the very act of possession provides unassailable proof that objects are not spirit, and fuels anew fresh cravings.

Following the trajectory of the virtual / material dichotomy as it stems from a classicist position of the mind / body split, and manifestations of the male / female divide, I propose feminist theory as a potent tool to effectively analyze the artistic and sociological implications of virtual-materiality. Plato conceived that the body is from the material world; and the soul is immortal, of ideas and universal truths, and does not exist in time and space. In this sense, the soul is temporarily united with the body and will separate at death. Descartes' theory holds that the body works like a machine with material properties, and the mind or soul is a nonmaterial entity. In this conception, the mind controls the body. I believe these dominant philosophical stances are instrumental in understanding polarities outlined in this text, and how they have come to be defined in opposition to each other. Traditional views equate technology with machine, attributed as male and related to the sublime and power; whereas beauty is often the stand-in and proponent for the aesthetics of the organic, the compliant and gendered female. Theorist Elaine Scarry discusses this perspective in *On Beauty and Being Just*:

...in the newly subdivided aesthetic realm, the sublime is male and the beautiful is female...Why should this bifurcation have dealt such a blow to beauty...? The sublime occasioned the demotion of the beautiful... Formerly capable of charming or astonishing, now beauty was the not-astonishing; as it is also the

not-male, the not-mountainous, the not-righteous, the not-night. Each attribute or illustration of the beautiful became one member of an oppositional pair, and because it was almost always the diminutive member, it was also the dismissible member. [5]

Scarry's critique around the issue of beauty provides pivotal clues and associations for a discussion of virtual-materiality within a feminist perspective. Once again, a 'pairing' of the sublime / beauty equals the virtual / material. But beauty, with its quicksilver qualities, helps to destabilize easy polarities. Dichotomized thinking sets the stage for an avalanche of 'thought', in all its virtual importance, overwhelming 'tangible', often just pretty and overlooked. At a micro-level, virtual-materiality, as continuum, is the antidote to definition and demarcation.

As a woman who came of age during second-wave feminism, I have a strong interest in formulating what a feminist position means to me as an artist, and particularly in my strategy of taking on an alter-ego. The relationship between myself and my avatar could be best characterized within a feminist context, as a mother-daughter bond. I have created Nar Duell, but I am at the mercy of her physics. Limitations and strengths determine what we can do together. I nurture Nar Duell, but it is the unforeseen and unknowable combination of what I have 'fed' her that makes the work live. But what of neo-feminism? From the simplest of decisions – what colour hair to purchase, to which friends to accumulate, one is always hyper-aware of gender in Second Life. Nar Duell's personality reveals a full range of contradictions. She strives to be nice, agreeable, conciliatory and shudders at the thought of looking dowdy for the sake of politics; but is thoroughly empowered when flying around in her super-cape. She wears a hard hat because she does a lot of building in Second Life. At the same time, she wears short, tight skirts, cat ears, fishnet stockings and stilettos – performing her own, one-woman, slut walk protest.

The reality of online virtual worlds is that they tend to be highly charged, sexualized places, full of fruitful data to examine contemporary male / female ideology and practice. The writers R. A. Brookey and K. L. Cannon, in their article *Sex Lives in Second Life* say "there was a great deal of optimism about the potential for virtual environments to offer users opportunities to explore multiple identities." [6] However, they conclude on a very different note: "Arguing from Foucault, we suggest that cyberspace should not be regarded as an environment that moves the user outside of the political and social matrix of gender and sexuality." [7]

We cannot entirely escape our bodies, our innate materiality within the virtual, since it is primarily a product of our history and societal imperatives. What we dream into existence is limited by what we have already, and what we have already is largely a product of what we are and the 'things' that surround us. Sometimes it appears as though the material trumps the virtual. However, the virtual is extremely robust and infects the real at the sub-particle level, making it impossible to root out. We only know it when we see it in the extreme.

My need to reflect on our human condition through virtual-materiality is a romantic notion. Although instead of peering only into the enormity we call nature (the material) and feeling awe (the virtual), I look into an abyss of technological change and find a similar wonder and incongruent beauty. Mess, obfuscation, bedlam, redundancy, contradiction – these qualities, redolent of humanity, are typically considered the antitheses of insight. They confound compartmentalization. Perhaps the necessarily chaotic can be an impetus for 'soft' thinking that relinquishes conceits of specialization and repudiates the polemics of division. By breaking down ideas of difference using visual and aural language, artists can directly encourage a bleeding of thought, sensory understanding and insight. Engagement through art stratagems can be powerful forces to find new ways of understanding that confound dichotomization and honour the idea of continuum.

MEDIATED EARTHWORKS: NEW MEDIA GOES WILD

SCOTT HESSELS

The artistic use of emerging sensor technologies in remote locations is resulting in artworks inextricably linked to dynamic forces in the natural landscape. Like Earthworks, these projects are shaped by nature, connected interactively with their environments but using technology instead of bulldozers to mediate. New media is introducing new types of environmental impact in sculptural, visual, cinematic, and narrative construction.

Throughout history, artists have taken the materials and forces of nature and used them in the creation of works. The sculpting of clay, the mixing of pigments both represent the use of natural or organic materials as servants to artistic inspiration. However, a subset of art has allowed that relationship to be reversed. Using a wide range of tools – wind, entropy, erosion, mapping – some artworks allow nature to be a physical, determining influence in their realization. These artists have shared their vision with the natural environment and transferred the power to shape its form to the forces of nature.

Recently, new media artists have joined this tradition and begun using data from the natural world as a driver for visual, temporal, narrative or dimensional components of their work. Taking advantage of the increasingly portability of computational sensors, these artists are 'reading' the natural environment and then using the data to shape artworks that exist in a mediated but symbiotic relationship with the natural world.

Easily understood as a type of data visualization, the projects often focus on the computational and can be associated with other information arts. Alternatively, they can be viewed as ecological art, tapping into the contemporary zeitgeist surrounding sustainable design. However, if one considers the interactivity of the works – nature as a collaborator – they fall rather interestingly into a history of Land Art sculpture. Perhaps by viewing these projects as Mediated Earthworks, we broaden both the depth of these artworks and our understanding of our complex relationship with nature.

The moving image is usually considered a mediated art form since it is difficult to separate kinesis from the machines that power it. However, kinetic sculpture is also time-based, often narrative, and its changes in shape, color, and even materiality share many qualities with cinema. Making this leap, one can consider the evolving form of Calder's mobiles and the rambling wind-powered sculptures of Theo Jansen as non-mediated moving images. In a sense, kinetic artworks are screenless cinema.

The Earthworks sculptures that began emerging in the 1960's were often sets of instructions that foreshadowed programming as well as made to change over time. Their innate ephemeral qualities – artworks that embraced entropy and change instead of battling it – made them temporal forms whose changing 'image' was part of the artists' creative strategies. As sculptor Robert Morris explained, "What art now has in its hands is mutable stuff which need not arrive at a point of being finalized with respect to time or space. The notion that work is an irreversible process ending in a static icon-object no longer has much relevance." [1] The sculptures had cycles, changing stages, life spans. Earthworks were images that moved.

Like the moving image, interactivity is also strongly associated with computation and media. However, interactivity can be purely relational, with no mediation required. Paul Willemen puts it almost bitterly, "To refer to interactivity as a new feature characteristic of 'new tech' discursive forms is, again, nonsense. Indeed, in many respects, the digitalization of information has rendered interaction between reader/viewer and text-production more restricted in that the protocols governing interactivity have become tighter, narrower, more inflexible, and more policed. The expansion of opportunities for interaction has become accompanied by reductions in the scope for action." [2] Part of that scope of action is limited by a view that interactivity must occur with machines.

However, interactivity may not be limited to Willemen's reader/viewer either. The emphasis on process and temporality of Land Art was directly tied to forces in the environment. It was a unique and radical form of interactivity, where context was given influence and power, forming a triangle to the reader/viewer relationship. The artist interacted with the natural environment, viewers interacted with the spaces and systems that were created, and nature would interact with the sculpture by reshaping it. Artist, viewer and nature were in a messy mix of interactivity...which wonderfully increased the unpredictability of each of the interactions.

This emphasis on time and process allowed viewers to look at the dynamics of the elements in the environment. One had to experience different stages of the system to experience the whole work. The physical forces of the landscape became an interactive driver for the realization of the visual artwork. It was

“a programmatic approach to the work and advocates sculpture which experiences, reacts to its environment, changes, is non-stable... art is gradually entering into a more significant relationship with the viewer and the component parts of his environment.” [3]

Changes in time led to changes in form and the Earthworks movement viewed sculpture as malleable, changing, entropic, and participatory. Earthworks connected physically with their environments and were designed to react to the forces found there. Nature was the hammer that pounded the sculptures, the brush that changed their colors. “During the period, many artists worked with natural materials, often fascinated by their evolution and their organic decomposition. To better observe this process, the artist became almost a laboratory assistant, engaging in artistic experiences.” [4]

Many of the Earthworks artists would probably contend that they were fighting the creeping technology and mediation of the 1960’s and took to the desert for its innate isolation and primitivism. It is ironic that many of the works were actually very complex systems and, when connected with the programmatic strategies evolving in Conceptualism and Fluxus, became keystones in the computational arts of today.

These artistic systems are celebrated as early ecological art but could easily be equally lauded as early programming art. Hans Haacke creating artificial ecosystems (“Rhine Water Purification Plant” 1972), Agnes Denes harvesting wheat in downtown Manhattan (“Wheatfield: A Confrontation” 1982), and Robert Smithson pouring tar down an eroded hillside (“Asphalt Rundown” 1969) all leaned on nature to do the heavy lifting and provide the meaning. The sculptures could not exist without the input of nature itself. The direct use of forces and processes in nature to create sculpture continues today. John Grade’s “Host” (2007) is partly sculpted by the local birds pecking away at the form of his work.

Today culture has shifted towards an emphasis on sustainability – how those ecological systems can continue on. It is an approach that empowers natural systems, giving them the capacity to endure. Sustainable design often incorporates a direct agency with environmental power – wind, currents, sunlight, etc. The highlighting of systems in nature has been replaced by a closer look at the forces of nature.

Tapping those forces means that artistic gestures can be shared with nature itself. Kinetic art has often recognized this possibility and used natural force as a method to change the form of a sculpture. Alexander Calder’s mobiles opened up sculpture to the dynamics of outside influences, for example. Two recent exhibitions of kinetic works have emphasized the forces of nature as a collaborator in the creation of an artwork. Guy Brett, curator of the Force Fields: Phases of the Kinetic show in Barcelona, explained that “we begin to see that ‘natural phenomenon’ and ‘aesthetic decision’ were at this time in a shifting and reciprocal relationship to one another. The working-out of natural processes was allowed to change the conception of the beautiful; artists ceded their ‘will to form’ to certain degrees and in certain ways, and allowed natural events to prevail, which was seen as an emancipatory process, and to offer deeper insight into reality.” [5]

The Drip, Blow, Burn: Forces of Nature in Contemporary Art exhibition at the Hudson River Museum presented artworks that used wind, water, and fire to shape the materials of the art. Curator Thomas Weaver observed that “the natural here is not just a subject, and certainly not just a material...moving natural elements are *primal* elements that, by rupturing the boundaries that govern the significations of visual art, embody the power of art to wrestle with the world.” [6]

Although wind, water and fire are dynamic forces to use as creative influences, they are just the beginning of the possibilities. Computer technologies have not increased the distance between man and nature, new sensors have actually introduced new types of environmental agency. Many natural forces are not directly tangible and now the invisible energy fields, patterns, rhythms and dynamics of nature are possible artistic 'shared gestures'.

Today, indiscernible changes in motion, light, sound, temperature, depth, and a host of other variables can be detected. Our newfound computational detail is spreading and giving us unique information about the natural environment. One of the largest initiatives, Hewlett-Packard's "Central Nervous System for the Earth," plans to release a trillion sensors into the natural and built environments. [7] Tiny wireless contraptions will swarm the planet giving real-time information on ecological systems, geological activity, energy waste, *etc.* We can now discover new types of kinesis in our environment.

Increasingly, artists are co-opting these stunning data streams for artworks. When the sensors are matched with timespans, data over time, we see the increased possibilities of nature itself affecting an artwork. Similar conceptually to Earthworks, these new computational versions have a key difference. Mediation is not limited to the photographic or video documentation of the artwork but now includes the actual collection and input of artistic materials. Media is no longer just presentational.

With sensor and datastream as a type of mediation, emerging technologies make it possible to create new media artworks in remote, wilderness locations. The miniaturization, portability, and cheapness of sensors, computers, projectors, *etc.* is leading to a body of work where the landscape is inextricably linked to the artwork. The list of sensing technologies is growing at a phenomenal rate; this includes commonly used sensors like GPS, DNA, motion, altitude, tilt, speed, light, sound, SONAR as well as emerging technologies in 3D/stereoscopy, 360 degree cameras among others. When matched with artistic strategies, we're seeing GPS Drawing, light and sound installations, projections, and a host of other technologies all using captured datasets that transform the artwork in real time as the data from nature is incorporated.

The narrative possibilities are also being explored when nature is used as a driver for story construction. The natural environment can now become a protagonist, not metaphorically but literally, in the evolution of a story. Sensed changes in nature can be used to select and present from databases of a wide range of media, creating real-time stories in text, moving image, sound, *etc.* One of the lures of exploring environmental agency is the hidden interactivity of the process. The narrative still allows for interactivity's flexibility, but is not controlled by direct human interface. Tomorrow's auteurs may be dynamic spaces.

The direct agency of the natural environment has been investigated by several artists. Mary Lucier's "Dawn Burn" (1975) used a video camera to record the rising sun until its rays left a scar on the image and eventually destroyed the camera's tubes – the power of sunlight directly shaped the visuals on screen. The Center for Land Use Interpretation (1994, ongoing) has initiated several projects that merge database arts with a proactive nature and have made advances in the art of mapping. Paula Poole and Brett Stalbaum have mixed painting technologies with GPS systems, and Haruki Nishijima has designed systems that capture ambient sound and translate it into light and motion. Sheldon Brown's "Video Wind Chimes" (1994) used wind sensors housed in streetlights that had been converted into projectors. Changes in wind changed the television channels being projected down onto the sidewalk.

In my own practice, I have also been working with the forces of nature. The “Sustainable Cinema” series (2009, ongoing) are kinetic public sculptures that use natural energy – wind, water – to generate the moving image [Fig. 1]. The artworks combine references to both the optical illusion toys that led to the invention of movies and early natural energy sources. By referencing the histories of both film and industrialization, these sculptures are simple illusions created with simple energy to make us reflect on how removed we are from the original magic of the moving image. It is a primal media experience, which due to the rapid development of cinema technologies, is no longer an oxymoron.

I had explored this direct agency of nature years earlier when I created a light installation based on the topography of Los Angeles’ famous Mulholland Drive. Together with programming by Michael Chu and sound design by Martin Bonadeo, we collected the tilt, altitude, location, direction, speed and sound of the drive and created an exact duplicate of the experience of traveling along the road in a 3D computer program. That virtual path was then used to control two robotic lights in a dark room filled with fog. Like cinema, direct data is captured, then edited and presented. However, here the environment directly defines the experience, the precise geography is used computationally. “Mulholland Drive” [Fig. 2] demonstrates how the rhythms, patterns, and random chance of the environment can be sensed through new media technologies and used to create new forms of visual experience.

Computational sensing, database aesthetics, real-time processing and visualization systems all can give new perspective on the natural environment. Working with science, media artists can now use the same materials that shaped the Earthworks movement like water, air, soil, stone, temperature, light, acoustics, topology, geography. However, with sensing, shared creative input can be given to natural forces and phenomena in those materials – flow, echo, wind, currents, reflection, decay, animal migration and behavior, topology, projection, and so on.

Once again, artists are reflecting society’s views on the environment but now with an emphasis on shared input – natural energy paired with creative energy. With emerging sensing technologies, hidden natural forces can also be used in artistic strategies. For centuries, nature has been celebrated as an inspiration for the arts. Finally, nature can do more than inspire, it can pick up the brush itself.

MEANINGFUL LANDSCAPES: SPATIAL NARRATIVE, PILGRIMAGE AND LOCATION BASED MEDIA

Megan Heyward

A range of locative projects involve navigating landscapes augmented with social or historical meaning. In what ways do they echo and intersect with older cultural practices involving spatial narrative and the walking of a meaningful landscape – the practice of pilgrimage? This paper explores pilgrimage as a form of spatial narrative, and the ways in which earlier notions of walking a meaningful landscape might inform location based practices.

Fig 1. View from Yakuoji Temple, 88 Temple Pilgrimage, Shikoku, Japan, September 2008. Photograph, Megan Heyward.

Over the last decade, developments in GPS and location mapping technologies have led to the emergence of many location based and spatial positioning applications, alongside a diverse range of artistic projects that work creatively with GPS data. While locative artwork and practice is a broad area, many projects can be categorised, according to Tutters and Varnelis, under one of two mapping approaches, “annotative – virtually tagging the world – or phenomenological – tracing the action of the subject in the

world." [1]

Many annotative locative media artworks involve navigating landscapes layered or augmented with personal, social or historical meaning. These include the placebased storytelling of Jeremy Hight, the Murrum Project, Yellow Arrow, Knife and Fork and many others, all of which affirm Hight's sense of "agitated space", of space "alive with unseen history, stories, layers." [2]

With the recent widespread rollout of 3G networks and the availability of powerful, domestic mobile devices, there has been a renewed interest in the application of location based approaches across a range of cultural contexts, particularly through annotating locations with archival images, texts, oral histories or other materials by the museum and cultural sectors. As cultural institutions increasingly move into locational spaces, and as location related tools, apps and devices become more accessible, it seems relevant to explore some of the ways in which augmented, meaningful landscapes have been a critical element in a much older cultural practice – the practice of pilgrimage.

In her 2005 article "On Spatial Perception," Nina Czegledy brought attention to the resonances between certain religious practices and augmented reality. Describing the sight of Buddhists simultaneously walking, circling stupa and praying in sacred sites in Lhasa, Tibet, she wrote, "While walking and praying in the yak-butter-lit, mystical space, the pilgrims appeared transported into an enhanced, symbolic world – an augmented reality." [3]

In this paper, I wish to explore some of the echoes and resonances between certain contemporary location based media practices and older cultural practices involving spatial narrative, annotated or augmented location and the walking of a meaningful landscape – the practice of pilgrimage. In what ways might an examination and understanding of pilgrimage practices inform our approaches to developing place-based storytelling experiences? And whilst I will focus here on some areas of commonality, I acknowledge that there are many areas of divergence. However, I'd like to explore some of these resonances; as a way of exploring how experiences of landscape, narrative and embodiment in pilgrimage practices might inform contemporary media practices concerning location, in particular place-based storytelling and spatial narrative.

PILGRIMAGE AND SPATIAL NARRATIVE

What exactly is pilgrimage? We might think of it primarily as a religious practice involving a journey of spiritual or moral significance to a specific location or set of locations that have been designated as sacred or otherwise meaningful. Originally referring to the European Christian practice of visiting specific sites associated with the life of Jesus or Christian saints, pilgrimage now commonly refers to particular meaningful practices that are present across many cultures and religions. These include Islamic journeying to Mecca, or Hindu and Buddhist pilgrimage to locations such as Kumbh Mela in India or Mt Kailash in Tibet. [4]

In contemporary culture; the word 'pilgrimage' is increasingly used colloquially to refer to meaningful, secular journeys to landscapes of particular personal, cultural or historical meaning. For example, the journeys of contemporary Australians to Gallipoli, in the Canakkale province of Turkey coinciding with ANZAC Day on April 26, are routinely described in the Australian media as 'pilgrimage'. Visitors are said to have made the pilgrimage to Gallipoli without any hint of irony or religious overtone.

Pilgrimage – both religious and secular – can be seen as both a form of spatialised narrative and as an annotative practice whereby specific locations are associated with narrative and meaning. Further, it is an embodied practice involving both an intellectual engagement with the stories associated with place; as well as an active journey and making sense of landscape and environment as it is experienced.

In “Wanderlust: A History of Walking”, Rebecca Solnit writes extensively on pilgrimage, as well as the contemplative nature of walking. Drawing links between geographic and spiritual terrains, she writes, “Pilgrimage is based on the idea that the sacred is not entirely immaterial, but that there is a geography of spiritual power.” [5]

There are numerous examples of the use of spatial narrative in traditional pilgrimage practices; notably the spatialised Christian crucifixion narrative known as the Way of the Cross or Stations of the Cross. In its early incarnations, 14th Century Christian pilgrims visited Jerusalem to retrace the final journey of Christ, walking the same ground, and often returning home with relics and artefacts. During the 16th Century, Franciscan’s built outdoor shrine replicas of the Stations In France, often incorporating the Jerusalem relics; and by the late 1600’s permission had been gained to build the Stations inside Catholic churches.

The Stations of the Cross involves a complex layering of landscape, narrative and walked, embodied experience. In Jerusalem, it traces or augments the landscape with Christian narrative – “landscape became text, and text was engraved into the landscape as pilgrimage.” [6] As the Stations journey is then reproduced and distributed into local churches, further degrees of complexity are involved – an abstracted representation of a journey; a virtualisation of real world locations; and the superimposition of a complex narrative onto a small number (fourteen) of signifying images. If we were looking for an historic antecedent to contemporary place based storytelling practices; the Stations of the Cross may be a significant example, involving “stories we can walk into to inhabit bodily, stories we can trace with our feet as well as our eyes.” [7]

Contemporary Christians continue to experience the Stations in several forms, including as a large-scale spatial narrative. On July 18, 2008, the Stations of the Cross was re-enacted on the urban landscape of Sydney during the Christian World Youth Day Summit. During this event, Sydneysiders saw key Sydney locations effectively overwritten with Christian narrative – the Botanic Garden’s transformed into the garden of Gethsemane; the Opera House into a torture site; and an ex-industrial wharf into the crucifixion site. Unlike the more traditional Stations experience, this re-enactment was not a walked experience, since large audience numbers made it impossible to shift people safely around Sydney within the timeframe. Instead it was a broadcast event; taking place in sequential, discrete locations, and reliant on simultaneous live media broadcast of location-specific narrative via large public screens.

The juxtaposition of the Sydney Harbour environment, including the utilisation of iconic, contemporary sites such as the Opera House, with a two thousand year old narrative that was effectively superimposed on the landscape, was, I believe, problematic, and at times distinctly uncomfortable. Although this may seem an extreme example; such an approach, which overwrites a location with an entirely unrelated narrative, is also deeply at odds with the location specific narratives and histories evident within many contemporary location based works; and to be fair, with the Jerusalem based Way of the Cross. Regardless of religious leaning, the problem of disjunct between narrative and place is an important issue to consider. Rather than superimposing upon location, it may be more effective to maximise the relationship between narrative and location.

SHIKOKU LANDSCAPE AND LAYERED MEANINGS

By way of contrast, I will turn to spatial narrative within a non-Christian context, focussing on the 88 Temple Buddhist pilgrimage in Shikoku, Japan. The pilgrimage is Japan's most popular Buddhist pilgrimage route, attracting thousands of 'henro' [8] or pilgrims each year to the island of Shikoku, in southwest Japan. Looping for over one thousand kilometres around the Shikoku coastline, and involving 88 temple loci; the pilgrimage is undertaken by car, bus, and still, at times, in its original mode, on foot. The pilgrimage relates to temples founded or restored by the famous Japanese monk Kukai, known posthumously as Kobo Daishi, a Shikoku native and significant historical figure in Japanese culture; being the founder of Shingon Buddhism in Japan, the founder of Koyasan on Mt Koya, and a renowned writer and poet.

Unlike many pilgrimages, the Shikoku pilgrimage is not seen as a strictly linear journey that culminates in arrival at one especially sacred place; rather it is structured as a looping, circular journey, where all eighty-eight locations are seemingly of equal importance. Unusually, it is a pilgrimage that can be undertaken discontinuously – one can begin the pilgrimage one year, undertake a portion of it, then return quite legitimately at any time, even years later, to pick up from where you left off.

There are several intertwined levels through which landscape and narrative are creatively aligned within the Shikoku pilgrimage. At one level, the circular nature of the route allows the Shikoku pilgrimage to operate as a type of sacred mandala; with the journey through the four island prefectures and to its temples roughly corresponding with the four stages of Buddhist enlightenment. [9] This is referred to in several texts and maps concerning the pilgrimage, dating back to the 18th century. Academic Ian Reader, who has written extensively on the Shikoku pilgrimage, writes, "The pilgrim's journey, therefore, is one that follows a path to enlightenment in which Kobo Daishi is both a companion and guide in the pilgrimage, while the island is envisioned as a sacred terrain, mandala and map of enlightenment." [10]

At another level, locations within the pilgrimage are associated with stories and acts concerning Kukai. Born in 874, Kukai is known to have undertaken solo journeys and austerities around Shikoku; notably to Mt Tairyu and Cape Muroto, where he had profound experiences that he later wrote about. Over time, through a blurring of the historical and the fictional, various legends or miraculous deeds have been associated with Kukai's presence or actions in particular locations on Shikoku. These real and imaginary stories – he carved a statue here, bringing life to the landscape; or he struck his staff on the ground there, causing a stream to emerge – have become part of the multilayered narrative concerning both the pilgrimage, and the island itself.

The Shikoku pilgrimage resonates strongly with Hight's notion of landscape agitated with unseen histories; where narrative is in a sense traced or carved onto the island through storytelling and association over several centuries, as well as through the embodied practice of walking. Ian Reader speaks of Shikoku as a moving text that is shaped and reshaped by the interweaving of historical and legendary narratives alongside contemporary pilgrimage experiences on Shikoku.

"In Shikoku, for example, there is evident correlation between the physical landscape and sacred narratives, in which the sites and settings of the henro are locations richly layered with complex weavings of meaning and textual representation. This richness of meaning inherent in the locales of pilgrimage provides a moving text for the pilgrimage, and allows scope for different participants to pursue their agen-

das and follow their own pilgrimage paths, which are themselves influenced by the settings and landscapes in which they are enacted.” [11]

At a third level, the Shikoku pilgrimage employs a device that actively and creatively links landscape and narrative through the use of ‘goeika,’ [12] which are poetic, haiku-like instructions or hymns. Each of Shikoku's 88 temples has a discrete goeika, commonly referring to the temple and the landscape or nature surrounding it, and posing Buddhist philosophical questions or instructions to the person undertaking the pilgrimage. Written in an arcane poetic structure, very few have been translated into English, however, those that have often refer to elements of the natural landscape such as the scent of wisteria, the fading of maple leaves, or the golden colour of water in a nearby pond. Posited often in the second person, present tense, they invite the pilgrim – and here I really want to say the word “participant” – inside the narrative; inside the island’s text or sacred mandala; exhorting them to engage with the landscape before their eyes; experiencing it not just as a map of historical narratives and miraculous deeds, but participating intimately in the environment freshly, as it arises. In effect, the goeika act to mediate the environment, providing a filter through which to experience the temples and surrounding landscape.

At Ichinomiya
Prayer is not easy
Roll up your sleeves as you pray
Seeking comfort in this world.

Autumn maple leaves
Scarlet or faded, perish.
Once more, springtime comes again
Unending and forever,
Death follows birth, birth follows death. [13]

These complex, intertwined relationships between landscape and narrative in Shikoku appear to indicate unexpected and intriguing correspondences with a range of contemporary location based and augmented reality practices. The Shikoku pilgrimage operates as a spatial practice; and the concept of the island as mandala supports the sense that the pilgrimage operates as a large-scale spatial narrative. The correlation of various sites with specific location-related narratives sees the pilgrimage operating as an annotative place-based narrative – a landscape augmented and overwritten with narrative, myth and miraculous acts. And the utilisation of the goeika within the pilgrimage indicates a further degree of complexity in the relationship of landscape and narrative. Through the use of a second person, present tense and the referencing of actual features of landscape and geography, the goeika act as triggers for a complex ongoing questioning and engagement with Buddhist thought in the context of the locations themselves.

As such, this multilayered relationship between landscape and narrative in Shikoku seems to facilitate an active engagement with location, and a somewhat reflexive, intimate dialogue between the past and the present; rather than representing a purely rigid set of concepts or histories that are tied to place. The potency of such an approach, where there is an intimate, fluid dialogue between the landscape, narrative, and participant can arguably also be seen in the work of various contemporary artists working with location; for example Blast Theory, Teri Rueb and Janet Cardiff, among others.

Over the last eighteen months, there has been a steep rise in the uptake of smartphones in many countries, at the same time as an increase in the application of location-based technologies within museum and other cultural contexts. Mobile applications such as Layar and Junaio easily support virtual annotation of the environment, however, issues of engagement and motivation can be problematic for both practitioners and audiences. While some services, such as FourSquare and SCVNGR, utilise challenge and reward models to maximise audience participation, these approaches are not always suited to historical or artistic location based projects.

As we work with annotative approaches to location-based media – as artists, historians or cultural workers – we face multiple challenges. Why should people engage with these projects? How do we keep people engaged in walked, location based experiences that are not necessarily treasure hunts, or do not offer obvious real world benefits or rewards? If we consider pilgrimage as an historic spatial practice involving the augmentation of landscape with narrative, histories and meaning – and additionally, one that continues to engage people in complex conceptual and physical journeys – what aspects of pilgrimage practice, might be useful to consider? It seems that the most potent, relevant areas to explore involve the experience of an augmented landscape which fosters an intimate, fluid and immediate dialogue between landscape, narrative, and participant; between past, present and possible futures; or between multiple narratives, ideas and histories. Such approaches are likely to involve strong resonances between landscape and narrative; however, these suggest neither a rigid, closed set of stories, nor an unrelated, superimposed narrative or re-enactment, but rather an active, intimate engagement with landscapes traced with multiple ideas and concepts; and with complex sets of meaning.

IT'S BEHIND YOU: THE PARAMETERS AND PROCESS IN THE CREATION AND PRESENTATION OF PANORAMIC MOVING IMAGES

DAVID HILTON

During September 2010 ICCI (Innovation for the Creative and Cultural Industries) University of Plymouth, UK, organised a 360 film, arts and performance festival in Plymouth city centre. Using the festival as a case study, this paper reflects on the parameters for and the processes involved in the preparation of creative content for the festival, particularly focusing on the issues and concerns pertinent to 360 film making.

During September 2010, ICCI (Innovation for the Creative and Cultural Industries) and the University of Plymouth, UK, organised a 360 degree video film, arts and performance festival in Plymouth city centre. The rationale behind this festival was to revive and re-engage with the popular nineteenth century tradition of touring panoramas.

Drawing on this traditional context, the ICCI festival also aimed to investigate the potential of panoramic spectatorship, utilising new innovative technologies of a projection screen format of six metres by twenty metres in diameter, high quality digital HD projection, digital surround audio and a performance space/auditorium housed within a demountable dome structure

The concept of the festival had been developed in line with the aspirations of LOCOG 2012 Cultural Olympiad in the South West of England; exploring the potential of a touring venue for the display of media and performance content. Using the festival as a case study, this paper reflects on some of the parameters and criteria established for the preparation of creative content for presentation within the Arena, particularly focusing on the issues and concerns pertinent to 360 degree film making. To do this we will review the display and presentation of film within the festival's 360 degree auditorium from three key aspects. First, we will reflect on factors that relate to the audience experience of panoramic content. Second, we will discuss how particular spatial and visual environments effect both the production and experience of presented work. And third, we will look at how these factors might be understood within a particular context.

As a result of the growth in panoramic photography [1] and recent developments in 360 degree video [2] there have been an increasing number of practitioners internationally who have been exploring this format as a creative environment. However, until recently the majority of the work produced has been limited: content has usually been displayed as interactive panoramas for computer screens, employing a computer mouse or touchpad as a means to navigate a 360 degree photographic or video space that is normally presented as a spherically mapped environment on a single screen. An emphasis for the festival was placed on the presentation of panoramic photographic imagery and video filmmaking rather than computer CGI animation, although examples of all methods were displayed.

The primary position for viewing the 360 degree image is from the centre of the auditorium. For the filmmaker and the film editor, this geographical positioning of the audience is both exciting while at the same time potentially problematic. The excitement emerges from the prospect of being able to place the viewer within the action - a step closer to Berger's map, [3] the replication of reality that might be

considered a holy grail for certain artists, particularly those filmmakers seeking to comment on, experiment with and play within what is real and its representation.

A simple and perhaps obvious notion is that the image is surrounding the viewer in a way similar to the viewer's experience of 'real life' and therefore the 360 degree experience could be considered to be more realistic than other methods. This concept of immersion is perhaps where the audience position becomes problematised, in that the viewer in real, not filmic, life is perceived not as being immersed in something but participating in an experience of the world from a particular place at a particular time. Immersion within a constrained environment, be it the virtual environment of a screen or screen goggles or the more geographical positioning within an enclosing visual environment like the 360 degree dome, is not the same as the more everyday experience of 'reality.' The constraint is the frame within which the experience purports to offer a new experience or perhaps understanding. A principal paradigm of film viewing and editing is the position of the viewer in relation to the screen, which is determined by the viewer's location in the arena and the direction they are looking; there is always a front and back to the screen area (although, during the ICCI 360 Festival some viewers were pressed against the wall, to gain better visibility or view of the whole screen). From this position the viewers witnessed distortion that mitigates the illusion generated by the 360 degree image. The geographical position of the audience determines their perception of the illusion; ideally they need to occupy the central space of the auditorium for optimal viewing experience. Inevitably this limits the audience members who have an optimal experience, as central auditorium space is limited no matter how large the auditorium.

Deriving perhaps from the proscenium arch of the theatre, we look into screens as we look into a book to read. Early panoramic paintings relied heavily on the inclusion of architectural structures, either 'faux terrain' or painted, to frame the images they depicted. The frame afforded by the screens represents a single field or point of focus and for the most part this is taken for granted in viewing. One of the most dramatic adjustments that needs to be considered when producing - or for that matter experiencing - 360 degree cinema, is the idea that, although one is working with a much wider frame, the viewer is not able to see and experience everything at any one time. While, particularly for a standing audience, there is the opportunity to move one's eyes, head and body to experience the complete screen, the viewer, schooled for many years of image consumption through various sizes of flat screens and by every filmic example previously experienced, holds onto single screen mentality and may struggle to reduce the screen horizon into a watchable frame. Unfortunately, in doing so elements of the presentation may go unseen behind the viewer.

This 360 degree horizon within which the audience is placed seemingly has the potential to offer unlimited opportunity to encapsulate a scene, an environment or a moment in time. In the natural landscape, our perception of the horizon is most usually associated with an unlimited field of vision. We might experience awe in landscape vistas, perhaps due in part to the prospect of infinity, outside of and beyond where we are standing. Other factors possibly mitigate against a similar perception within the Arena. For example due to the organisational constraints, the base of the viewing screen within the 20 metre diameter structure was placed 2 metres above ground level; the top of the screen was therefore 8 metres above head height. Our evaluation of this configuration determined that the screen required the audience to continuously look up to experience an on screen display. During the previous tests, conducted in a smaller 12.5 metre diameter structure the screen base was 1.4 metres above ground level with a 3 metre high screen terminating 4.4 metres above ground. The lower screen configuration and perhaps the smaller space provided an improved sense of being immersed within the film or photographic environment. With the larger diameter screen, the experience of gazing at panoramic views of the sort al-

cluded to above, one was not awe-struck in the same way since their promise of infinity was quite pragmatically restricted to the geography of the structure, the horizon of which ends with the screen. Yet an idea or expectation of unrestricted horizon is built into the idea of the 360 degree image. This duality of ideas and experience is an interesting and unexpected conundrum of the 360 degree processes. The Projection within the 360 Arena offers a sense of an immersive experience but is also a framework for construction of that experience - the viewer has work to do.

It might be said that an important function of the relationship between viewer and screen in cinema is the viewers' anticipation and expectation of 'what next.' The events that are unravelling on screen presuppose a series, with one event or situation replacing another. As viewers we are in a state of expectation that will be relieved by the appearance of 'what next,' but this relief is immediately replaced by a new 'what next.' What if the 'what next' might be happening behind you? What if the 'what' also brought with it a question of 'where?' What if it were possible to have protagonists between scenes appear at different parts of the auditorium, within the horizon of the 360 degree screen?

In allowing for the illusion of placing the viewer within the geography of the action, the filmmaker has also to consider the time it might take the viewer to shift position to see something happening behind them. To an extent the filmmaker has lost control of the framed image and cannot predetermine the focus of the viewer's attention. In this respect, the production and editing of a 360 degree work allows for new ideas in editing that perhaps use things the viewer can see; such as movement, colour and contrast. And in addition to this, devices the viewer cannot see (but might hear). Teasing, perhaps. Does the video editor allow for a time lag in cuts/transitions so the viewer might adjust their viewing position, or run the risk of the viewer missing parts of the action? Should a shift in action and visual focus around the 360 degree screen be signalled, indicated or aided perhaps by a shift in sound – particularly if one is working with surround sound?

The editing of all film and animation for the festival took place using a five screen linear format in preparation for the five-projector display method that was employed in the 360 Arena. This was not an ideal solution; inevitably screen three became the centre screen for editing purposes with screens one and five (which in projection would be joined) at opposing ends. The consequence of this linear format highlighted a number of interesting editorial issues. There was great pressure for screen three, due to its central position to become the focus for editorial decisions particularly those based upon visual composition. The natural and human desire for symmetry during the editorial process became a factor that had to be consciously overcome if the link between screens one and five was not to appear disjointed and the images were to retain the benefits of a 360 degree layout. A number of the works composed of still images used the stitch process of blending a number of images to produce a whole panorama. This stitch effect was also used in a montage way by a number of filmmakers as they compiled a number of different images to produce a whole composite. An example of this would be; "Cortical Songs," movements one & two, by John Matthias and Nick Ryan, (Matthias and Ryan 2008) performed by the String Ensemble of Trinity College of Music, conducted by Nick Pendelberry. [4] This 360 projection piece constructed by the co-author David Hilton was made up of single camera recordings that were edited onto 5 separate screens to remain in sync with the music. The effect was successful, largely due to the splendid camera work of Robin Cox directed by Andrew Graham Brown, which deployed balletic craning and tracking camera motions. Perhaps because the orchestra was not seen in the round there was no single geographical centre for an audience member to experience the film, instead he/she was able to access the separate screens within any part of the circular screen that was visible to them. The structuring of the of the work started with all screens showing the same image repeated, following the expectations associated with viewing a single screen. Gradually different images or camera views were introduced on

separate screens. As the work progressed, each screen would present a different view of the performance with close ups on performers from different parts of the orchestra. In this way, the editing worked with a narrative both of the progression of the musical piece and the audience's engagement with it. Gradually, the audiences were encouraged to see what might be happening behind them and make full use of the 360 degree environment. [5]

The Ladybug 3, [6] 360 degree video camera was used for a number of productions presented within the ICCI 360 arena. This device captures video using six cameras: five around the horizon and one above to produce 80% of a hemispherical image. Within the ICCI Arena, only a cylindrical slice of this image was used for projection on the wrap around screen, the screen did not extend to the full dome ceiling. The Ladybug 3 offered the obvious choice for film that recorded full 360 degree panoramic video imagery. Only a few of the works used the Ladybug 3 as the sole source of imagery. Perhaps the most effective use of the camera was in the production of *Panoptica* by Craig Whyte, Andy Banks and Jo Plant. In this work, the producers combined live action single camera shots with live action shots using the Ladybug camera and C.G.I. effects and environments within which the protagonists of this science fiction film interacted.

The ICCI 360 screen marries both theatre and cinema and creates an entirely new experience. In conceiving the 360 film. I first thought about early cinema, largely due to the technical limitations the 360 Ladybug 3 camera created. For instance, in early films such as those created by the Lumiere brothers, all the action took place within one static shot with few cuts. In this sense, shooting on the Ladybug is the same. But it also connects the medium once again with theatre. The camera becomes the audience and the actors perform their roles within a single space. In this case, you're working on a 360 stage. [7]

The conceptualisation of the space when planning action within the 360 arena also presents problems with the design and construction of the work due to the fact that one cannot see it as it will appear, except in the 360 environment.

The best way to do it was by doing a floor plan - a bird's eye shot to see how we use the space using the 360 camera - I don't think we would have been able to do it without the plan.

There were certain scenes that worked in the film – for example the ventilator scene, that was a bit surprising, you have the main character who has escaped and ends up in this vent shaft and when you watch it as a single screen it is quite boring - but we were quite surprised watching it back in the 360 how interesting it was because he was going all the way round the 360 degree screen crawling in that space and that is the first time the audience actually get to just to see that main character. [8]

The process of production is not automated and no matter how inventive in its conception each work was the result of painstaking production processes. The degree of detailed work involved in production is perhaps exemplified by Udo Hudemaier's piece *City of Plymouth* produced entirely using still images. Each image underwent a high degree of processing; particularly evident in the shifting of perspective as each window of a high rise office was seen square-on without perspective distortion while its setting flew up and down the buildings, an effect produced by photo manipulation one frame at a time. Other producers had different problems but each had to devise a strategy for maintaining alignment of individual images to create the synchronous whole image on projection. Perhaps two methods most used were to assemble the whole 10:1 ratio panoramic image in a programme such as Adobe's "After

Effects,” necessitating use of the flat one screen image to represent the enclosing panorama. Another method was to fragment the sections of panoramic images into five single screens, which then were augmented with other footage and effects – one screen at a time. In this latter method the sense of the wrap-around panoramic image or ‘suggestive image space’ of the work was more difficult to sense during the edit. [9] In all cases the only time the work was seen in its intended form was during the exhibition inside the dome.

CONCLUSION

The experience of preparing creative works for projection within the ICCI360 Arena has raised many subjects for further research. In this paper we have identified just a small number of these subjects and have outlined:

The large numbers of international creative practitioners who are exploring the 360 degree format are limited to the presentation of their products as navigable spherical images presented within the frame of a computer monitor. Within the computer screen one notionally has complete access to 360, but the computer screen always frames this. Whereas the frame established by the screen in the dome seems to be unframed, it is in fact the dome itself, which provides a frame: the 10:1 aspect ratio of the projected image is a very narrow window. This could be construed as a possible inhibitor of an immersive experience. The 360 degree projection environment presents further possibilities and problematics for this work.

The significance of the size of viewing space and the position and size of the viewing screen relative to the audience is an important mediating consideration. And further, the importance of viewing the 360 degree projection from the centre of the display for an optimal experience of the panoramic image necessitates a restriction in the size of audience. The scale of the immersive experience may be a factor for further exploration with regard to the 360 degree horizon and the height of screen: looking up to horizon or down upon it. [9] If the projected visual horizon is not at eye level the viewer’s ability to relate to landscape is mitigated. If the image horizon is above the viewer it is related to as a picture on the wall, but if lower than eye level, one is more likely to be immersed and encounter a feeling of presence: the viewer needs to look ‘at’ or ‘down on’ and not ‘up to’ the image.

Of the many issues in production for the 360 environment, we should identify the following as of particular concern for future exploration: In constructing action and narrative sequences that employ the full scope of the 360 degree screen one runs the risk of the audience missing parts of the action which might take place behind, where their attention is focused. Should producers allow time for the audience to change their focus and indications - perhaps using sound to suggest this? Other devices include tracking action around the 360 degree screen by isolation of certain key points of attention such as actors/figures moving or the de-focusing or blacking out of other parts of the action. Currently the editing process requiring single screens to be laid out in a line of five may lead to over use of the symmetrical structuring of screens and a focus based on screen three (which is in the centre of the edited image) and screens one and five becoming disjointed. The degree to which one might employ a full 360 panoramic image in relation to images montage - constructed of 5 single screens - also affects the experience of the work. It does seem crucial to the development of this form, that editing facilities are developed that permit visualisation of the work during editing.

The gap between what is in front and behind and the audience's focus of attention represents an opportunity to exploit and explore a conceptual space that might be described as an interpretive space, and this provides a creative opportunity for future development.

THE METAPIANO: COMPOSING AND IMPROVISING WITH SCULPTURE

RICHARD HOADLEY

This paper concerns the implementation and control of interactive sculptural interfaces, designed to be used by the public as well as by musicians or dancers. The main device under consideration is called the Metapiano, an interface developed to trigger and modulate an array of musically expressive algorithms. The paper describes interactions with hardware and software systems and the nature of the music created.

Fig. 1. Hangings with Glyphs, 2011, Katy Price and Andrew Nightingale, Canvas/conductive paint.

Fig. 2. Metapiano, 2011, Richard Hoadley, Aluminum sheet, steel, wire, acrylic, Arduino.

1. Introduction

This paper concerns the design, implementation, demonstration and control of interactive sculptural interfaces, designed to be used by the public as well as by specialist performers, such as musicians or dancers. The main device under consideration is called the Metapiano, an interface developed to trigger and modulate an array of musically expressive algorithms using a (synthesised) piano as the primary sound source.

The paper describes the manner in which a viewer/performer interacts with hardware and software systems, examines the nature of the music created, and details how the two are related. Of particular interest is the way in which the resulting music relates to both new and more traditional forms of composition, performance and improvisation.

2. Related Work

With the advent and growth of accessible methods of physical computing, generative composition and real-time synthesis, there has been a similar expansion of interest in more practical and physical aspects of music making. That which was considered some years ago as a fringe activity for more experimental musicians and engineers (Theremin, Partch, Cage), has become increasingly mainstream and has enabled progressively more intimate collaborations between the arts.

This growth has been primarily focused on the musical interface - digitally through the graphical user interface, physically through the invention of new instruments and generatively through the development of algorithms to enhance, replicate, replace and analyse, human activity. [1, 6] Of course, analyses of human behaviour have demonstrated the complex relationships between the activities that can account for our behaviour – strategies, planning and construction – as well as our direct physical interference with the world. [10]

These developments in software have been reflected in movements in the cross-disciplinary field of physical interaction with software through hardware. The introduction of the Arduino in 2005 has been seminal in encouraging those from more creative disciplines to investigate issues of HCI and expression. The practically based work of Nic Collins, Perry Cook and O’Sullivan and Igoe is of particular importance here. [4, 5, 9]

The work of Alexander Calder and Ives Tinguely is clearly significant to the physical form of the metapiano, while its use as a musical interface adopts some ideas developed in Earle Brown’s ‘Calder Piece.’ [3]

3. Triggered, Gaggle and Wired

Triggered is a dance-music project that has been evolving since 2009. The core musical group of Tom Hall, Cheryl Frances-Hoad and Richard Hoadley was invited to collaborate with choreographer Jane Turner and her dancers in the creation of an interactive performance for the Human Computer Interaction conference held in at the Cambridge University Computer Laboratory and Microsoft Research. In an afternoon, a fifteen-minute dance-music performance was devised involving dance, physical interaction, algorithmic and human-controlled music generation and instrumental music performance. My contribution was the Gaggle ultrasonic interface. [8]

In June 2010, an extended production of *Triggered* took place at the Symposium on New Materialisms and Digital Culture at Anglia Ruskin University. This performance involved two new sculptural interfaces: *Wired* and *Gaggliina*. [8] Before and after each performance the public was encouraged to investigate the devices themselves and how they are used to generate musical material.

The 2011 *Triggered* production was further developed for performance at the Kings Place in London. Both *Gaggli* and *Wired* were rebuilt using more usable, stable and dramatic forms and two new devices were built – a set of three canvas hangings painted with a variety of symbols and the *metapiano*, a metallic, Calder-esque mobile.

In order to allow the dancers movement around the devices without obstruction, they were designed to operate wirelessly, hanging from the lighting rig of the venue.

4. Hangings with Glyphs

Figure 1 shows the three hangings created by writer/poets and now artists Katy Price and Andrew Nightingale. The hangings are made of unfinished canvas and both ordinary and specially prepared conductive paint, which provides touch sensitive areas on the canvases. The panels include a variety of images referencing widely differing origins: cave paintings, modern computing symbols, antennae, etc. As music interfaces they investigate links between sound, image and meaning as well as drama and expression in performance.

During both rehearsal and performance, the dancers spent time investigating the panels and indeed, when the configurations changed slightly between rehearsal occasions, complained that this hindered their learning ‘how to play’ the hangings.

In terms of capacitive touch, this was one of the most fragile and unpredictable devices. It was particularly difficult to ensure that touching actually provoked a response (and the reverse, making sure that a response didn’t happen constantly). I suggested a few times that from my position in front of the laptops, I could trigger some events occasionally. I was surprised by the vigour with which both dancers and choreographer rejected this on the grounds that it would be ‘cheating’ and, perhaps more seriously, that it would undermine the attempts of the dancers to learn how their instruments worked.

5. Metapiano

Of all the devices mentioned here the *metapiano* is the most complex, both in terms of hardware and software. It was conceived as an experimental multifunctioning object that could be played, or operated by a variety of types of performer, including members of the public, in a variety of settings. Reflecting this, there would be a variety of performance modes, including a standard music performance mode, where a musician would perform in a fairly traditional way, using the device as a performance interface. The mode utilised in *Triggered* is different: the dancers employ the power of movement and gesture as well as the algorithmic nature of the music produced to create a hybrid performance including music, movement, drama as well as, of course, dance. Another intended, but as yet unexplored mode, involves members of the public in gallery-like environments (although they could be anywhere appropriate) interacting with the device individually or in groups, and in doing so creating their own composition

or compositions. This has happened quite successfully with the original Gaggle at events such as HCI 2009.

In these situations, what is a piece of music, or a performance, and how does it differ from sculpture, sonic or otherwise? There are many examples of algorithmic and interactive art pieces that respond to movement, touch and pressure or that simply unfold over time. [6] One of the consequences has been the generation of a certain type of music: generally ambient or highly pattern driven or stylistic. I was interested in reflecting the mood, style and intention of a traditionally structured piece of western art music. One that struck me in particular was a composition that I was fortunate enough to encounter at this time, *Lune Rouge* by Alissa Firsova. [7]

This composition (and its performance by the composer) was about as far from what one might expect from a musically generative computer programme (it wasn't to my knowledge!); this is what drew me to it. Not only was it highly expressive, it was gentle, colourful, melismatic and above all structurally satisfying. It was rich and original in its use of harmony and colour.

The metapiano, as with all devices mentioned, operates through a variety of sensors, the data from which are captured and transmitted by Arduino boards of varying configurations. The data are transmitted via Bluetooth modules to the SuperCollider audio environment, where they trigger or modulate a variety of high, medium or low-level algorithms.

One of the key sensors works through capacitive touch and is based around a 555 timer chip circuit. In addition, a force resistant sensor (FSR) was included on each of four of the leaves. A performer could both touch and squeeze a leaf and by doing this generate data for immediate sonification. When touched, the capacitive sensors send a signal to one of the digital inputs on the Arduino microprocessor board. This in turn transmitted a '1' when touched and a '0' when isolated. The FSRs (and indeed the bend sensors when implemented) output between 0-5 volts; this is sampled and given a value between 0-1023.

The lowest level algorithm is simply a SuperCollider synth, a sampled piano, which plays a single 'note' event and allows for control over particular musical parameters.

This simple event provides the basis for all higher-level algorithms. As an example, one of these generates arpeggios, imitating some of the most characteristic passages of the Firsova. The function creates gestures made of arpeggios. An arpeggio is made of a number of sub-arpeggios, each containing a number of notes, usually three or four.

Through arguments, the number and value of these parameters can be modulated or randomized, as can a number of others such as tempo and starting note. Amplitude is controlled algorithmically, or through another sensor such as an FSR or bend sensor.

As a message is transmitted by the Arduino board at a minimum of about 50 times a second, if an arpeggio were to be generated every time SuperCollider received a '1' value from the metapiano, there would be many instances of the same algorithm occurring simultaneously, overloading the synthesis engine and swamping the musical texture. In order to control this, a counter is implemented and incremented with each '1' message. Only when the counter has reached a certain value does the function trigger an

arpeggio. Even then, another counter is kept gauging the number of arpeggios playing at any given time and a further limit is placed on this.

It is in the creation and manipulation of configurations such as these that much of the detailed composition occurs. The arrangement described above causes a sufficiently prompt response for the performer to feel physically responsible for the sonic event, while ensuring that neither the musical texture nor the computer's CPU is swamped.

My original intent was that many interlocking algorithms triggered by different physical events should be configured so that they create a satisfying, varied and multi-layered 'composition' with a significant 'improvised' component when even an unskilled/unrehearsed performer, whether dancer or member of the public, played with the device. Due to the demands of performance and audience and lacking the luxury of many days of experimentation and rehearsal, I decided to supply a safety net in the form of a scheduled series of events – a seven-minute (approximately) algorithmic composition, although this can be lengthened, shortened or restructured easily. With this in place, whatever interactions the dancers instigated, there would be some thread to follow, some overarching structure.

So that the dancers should trigger appropriate events at appropriate times, the composition was structured using what I called 'scenes.' These were implemented as top-level functions directing the triggers from the real world towards particular sets of mid-level functions. During the first scene, a touch would be likely to generate a chord or small set of chords, a single arpeggio or small melisma. A subsequent scene would direct the gesture towards the generation of an arpeggio such as the one described above. Other scenes triggered rhythmic chords or microtonal swirls of notes. The use of scenes promises much in terms of a more 'improvised' and less scheduled musical structure. By allowing either the change of scene automatically, or through another as yet un-invented device, it should be possible in future to allow for more improvised experiences while maintaining feelings of structural dynamism and unity.

As a composer who was trained in the western art tradition, I find it a constant struggle to relinquish the layers of control so often necessary to the successful implementation of one of those earlier creations, and yet I am very drawn to the enabling freedom of expression allowed by technology. While I was unable to let go of the structures of western concert music sufficiently to risk the improvisation that was my initial aim, the structures created at least in principle provide a workable method to achieve this.

What is left are questions regarding the nature and importance of the interface itself: whether the nature of the devices and creations described above make a significant difference to the way people interact with them; or, indeed, the type of musical events or even structures they create.

A significant hint as to the answers to such questions may lie in the reaction of the choreographer and dancers to some aspects of the interaction with these devices during the small amount of rehearsal time available. Since there were of the complications involved in the activities described above – not least the batteries running flat or Bluetooth disconnecting (for instance) – I made it clear that I could and was prepared to trigger events from my own laptop, so that 'something' would happen. The choreographer made it equally clear that she and the dancers did not want me to trigger anything. This would, in their opinion, be 'cheating' and would cloud their ability to understand what was really happening in their interactions with the devices. In other words, even if there was a problem with the interface, it would be better for this to be openly the case. Whether this purity of approach would have been so welcomed had

there been serious problems with the performance will, fortunately, have to wait for another production as, in the event, there were no serious technical issues to contend with.

6. Conclusions and future developments

At least as far as the Metapiano is concerned, the Kings Place performance of Triggered represented a significant milestone in the development of this work, but not a zenith.

Suspending the devices proved an excellent idea, and was highly effective dramatically – this has opened up many options for future development. Any future use needs to consider the use of pulley systems to enable the devices to be easily raised and lowered. For venues where hanging objects from the ceiling or lighting rig is not feasible, boom stand systems would be a good idea.

Although the Bluetooth devices used for wireless communication worked well, I would prefer to use open, non-proprietary solutions where possible and so devices, such as the XBee, and systems making use of them, such as ‘Sense/Stage’, should be investigated. [2]

Less prosaically, the hanging panels revealed significant potential for the use of semantic links between image, paint and sound in the design of the interaction.

Of greatest significance is the development of these technologies for therapeutic uses in the ‘Touching Sound’ project, an international collaboration between musicians, therapists, programmers, psychologists, artists and others. In spite of many years of research into human computer interaction, there have consistently been issues with the explicit adoption of technology in therapeutic environments, not least because of the way in which clients and practitioners view such technologies: as unnecessary and intrusive. At the same time, there are many ways in which technology can be used productively, for instance in the spontaneous generation of aesthetically interesting artefacts as well as in the exploitation of kinesthetic and multisensory elements, such as those described in this paper.

The Touching Sound project seeks to describe, implement and analyse work that investigates unique methods of articulating and implementing expressive gesture, synchronisation and entrainment, primarily through shared physical interaction with objects. This includes the implementation of custom-designed and built hardware and software using methods that are as close to invisible to clients and practitioners as possible while still maintaining the benefits of cutting-edge digital technologies. In particular, activities in music performance, dance and various physical and arts therapies are considered.

All of these activities emphasise one thing: the links between composing, improvising, performing and the nature of the physical interfaces used are of crucial significance in many forms of music and that we are approaching a point where a fuller and more open experimentation with such links is becoming conceivable.

BUTTERFLY WINGS OF PYTHAGORAS

JOANNA HOFFMANN

In my paper I recall Pythagorean idea of Universal Harmony, the first model that integrated the human inside with the rest of the world, questioning its validity in our times as well as its role in the process of redefining our humanity and relations with the nature treated no longer as the object of exploitation but as the subject of civilisational transgression.

IN PYTAGOREAN UNIVERSE

When we look at the "Millennium Simulation", the most ambitious visualization of our Universe made by Virgo Consortium, and we juxtapose this impressive model with the image of human neural connections, we immediately notice uncanny similarities between these two complex systems. Is it the result of tools used for these visualisations or maybe there are actually more similarities than differences between the macro and microstructure of our Universe?

It was Pythagoras who first connected the human inside with the cosmic space. His idea of the Universal

Harmony has been considered as the most important, influential and beautiful concept born by the human mind.

Pythagoras believed that the whole Universe was music. He divided it into *Musica Mundana* (later known as Music of Spheres) and *Musica Humana* (music of the human body). Pythagorean Harmony was based on numbers and proportions. For him a triangle connecting distant stars, drawn on sand or heard in a triad chord meant the same – they expressed Logos, the hidden order of the world.

His system united philosophy, science and art, influencing their development. With time, their paths separated and today, as Gyorgy Kepes noted, our understanding of the world is divided into the rational knowledge frozen in words and numbers, and emotional knowledge embedded in sensual images and feelings. To regain an integrated vision, a consciousness that could apprehend all the richness and diversity of our experiences of the world, we have to use all our abilities to “merge the scientist’s brain with the poet’s heart and the painter’s eye.” [1]

By entering (with my poetic heart and artistic eye) the sphere of mutual relations between science and art I recall the beginnings of this union and ask about the validity of the Pythagorean idea of Harmony in our times. I begun my investigations with a series of works devoted to relations between micro and macro scales, between *Musica Mundana* and *Musica Humana*, The series employs a musical adaptation of the Music of the Spheres by Johannes Kepler, the father of contemporary astronomy, as well as data obtained by means of radio telescopes and other devices used nowadays to explore the Outer Space.

I paired this material with microsounds of my cardiovascular system and later brainwaves, discovering in them fascinating musical structures, with resonances and aliquots reaching all accessible to us octaves. It is worth to underline that for Pythagoras identifying the world with music was not a metaphor but the answer to his search for arche, the essence of the universe.

The series ends with the multimedia installation “Tones & Whispers”, presented at the Dana Centre/Science Museum in London in 2005, and realized with the support of the Institute of Neuroscience at the University of London. In this piece cosmic and human soundscapes merge and images of my brain mix with those of distant stars and galaxies. In fact my brain replaces here the Sun: the centre of Kepler’s celestial composition and of the universe of his times.

Today we know that our Solar System is not the heart of the Universe. Quite the opposite, we rotate on our small planet around one of a billion of stars on the outskirts of our galaxy, one of millions of galaxies racing through the Space, or, strictly speaking, together with the Space. Where should we look for a point of reference, then? One possibility is to focus on the brain and mind as its function; the nexus of individual sensations and perception of the world as well as the source of all ideas and concepts including the idea of the Harmony of the World. We can go even further and stop thinking in categories of centres (and peripheries). Then we may recognize the brain-mind unit as a “knowing-becoming-participating-valuing system functioning within a 'spacetime' context described by the synergetic collaboration between information within a system and information from outside systems”. This approach suggested by Tamar Levin [2] links the individual nervous system not only to biological/genetic, historical and cultural experiences but to a greater undivided whole: to the information space and energy of the universe. Looking again at the Millennium Simulation, one can imagine that somewhere in pulsating nooks of its vast volume, there is a fractal mote (his/her brain) that manifests the deepest creativity of matter: the intelligence of life.

LIFE MATTERS

During the last century, our knowledge of the world and of ourselves has expanded tremendously. Today we know that we are made of the same components as the rest of the Universe. Thus, it is optimistic to think that at the atomic level, as part of the universal recycling, we are practically immortal. Nevertheless the question: “what makes us alive?” remains unanswered. Today we acknowledged that Aristotelian definition of life, based on the notion of a living organism, is no more valid because life “happens” on the molecular level. Biological sciences claim that only DNA is alive, making the rest of the organism merely a part of its much larger habitat. What is confusing however, is the fact that no inherent quality has been found in a replicating gene that would differentiate it from the inanimate matter. The phenomenon of life turns out to be very context-dependent.

The shared genetic heritage of the animated matter makes us realise the biological unity of all life on the Earth. The harmony of nature however conceals a ruthless struggle of genes for survival and does not favour its components. Considering the ease with which our cells start to reproduce foreign genetic sequences, it might be concluded that if mankind is ever wiped off the surface of the earth, it might be the result of the lost “gene war”. Moreover, just like the extinction of dinosaurs, it would not disrupt the phenomenon of life and its further evolution. I referred to questions about the substance and meaning of life in my multimedia project “Life matters” realised during my residency at the International Centre for Genetic Engineering and Biology in New Delhi in India where I was working with research material on malaria, SARS and AIDS. I continued my investigations in the project “Proteios” developed at CEMA Centre for Experimental Media Art / Srishti College of Art, Design and Technology and the National Centre for Biological Sciences, Bangalore, India in 2009.

HIDDEN TOPOLOGY OF BEING

We usually identify life with the processes of maintaining and transmitting information and knowledge both at the biological and the cultural levels. Obviously, it is not the only interpretation. Life is also, to quote S. Symotiuk, “the way in which space exists, and vice versa; space might be treated as the way in which life exists.” [3] This tautological sentence has its consequences. In our common perception our reality is made of four dimensions but according to the superstring theory it contains additional dimensions compacted to the subatomic level and hidden from our limited perception. All dimensions are liquid in their interconnectivity, and the space-time is no more defined by “specified points” or “corpuscle” but by minute strings which vibrations secure diversity of matter. Our anew musical universe coupled again science with aesthetical desires. “If guitar strings can create the splendid music in the three-dimensional space - writes the physicist Saul-Paul Sirag - think how exquisite must be the music in the nine-dimensional space!” [4]

We assume that we are connected with ourselves and environment in much more subtle ways than told by our senses, but we have to wait a long time before the evolution of our brain will overpass its current limitations and allow us to fully experience our multi dimensional existence.

Meanwhile we have to rely on our imagination and use available keys for its stimulation and for representation of our assumptions. In my artwork “Hidden topology of being” I use a model of a protein molecule as a space-time unit of my “liquid universe”. Its folded globular form brings to mind Calabi-Yau manifolds, geometric formations containing contracted dimensions, whilst exposed to X-rays it shows an

arrangement of atoms that might serve as a map of the starry Sky. Bridging micro and macro scales, scientific imagery with daily recordings and poetry, I translate scientific ideas into the area of art as a source of personal and collective consciousness inviting intuitive examination of the unfathomable nature of our reality.

The structure of a protein is used also in my interactive installation “Molecule”. Here the 3D model of its atomic arrangement merges with ever-changing sequences of video-animations referring to basic elements and states of matter. The installation creates a dynamic and contemplative landscape, a kind of atomic puzzle, underlining the fundamental homogeneity, instability and interdependence of components of our world. The interactive aspect of the installation enhances the experience of belonging to some dynamic system of interconnections.

FROM HARMONY TO SPECTRUM OF POSSIBILITIES

Pythagorean idea of the universal harmony has not gone stale but evolved together with changes in our knowledge of the world. In the 19th century, theories of evolution and thermodynamics introduced motion and variability to the otherwise stable cosmic composition, while non-Euclidean geometries opened the way for new space-time theories and interpretations. At the threshold of the 20th century, quantum physics confirmed Pythagoras’s intuition, igniting our modern imagination with vibrations of micro-strings of the matter in eleven dimensions. Greek Tetractys was replaced by physical constants describing the Universe in which the biological life evolved. Seen in a new light, the oneness of nature finally rebutted our long-built illusion of our privileged position in it. The proud Renaissance monument of the human being as a measure of the Universe cracked and old Pythagorean attitude emanated through its crevices.

Born out of the observation of the chaos of the world, Pythagorean Harmony searched for interconnections not for hierarchies. Today we learnt that synchronization, adaptation and interaction are at heart of deterministic chaos that rules natural phenomena. Its notorious “butterfly effect”, in which the slightest perturbation of the system leads to unpredictable but expected and unavoidable changes, proves the fragility and dynamics of relations between animated and non-animated, micro and macro environments. By all means, it concerns also the human being from his genetic code, social behaviour to mental processes.

We learn to accept that nothing in our world is for granted and there is no defined future only the spectrum of possibilities.

Paradoxically the progress in science and technologies together with the crises of humanistic ideologies give us an opportunity for re-questioning and redefining our humanity and for a renewed approach to nature treated no longer as an object of exploitation but as a subject of civilisational transgression.

BACK TO THE UNIVERSE

Our spiritual, intellectual and physical environment is changing rapidly. We cannot foresee how quantum, biogenetic and computer revolutions will transform our lives and ways of our thinking. Nevertheless using the very poor knowledge we have today we can make some random predictions and direct our endeavours.

Inspired by scientific breakthroughs in search for water in the Universe, I visited La Reunion, a tiny island

on the Indian Ocean, a home of SALM – Moon/Mars Analogue Site, serving the research towards our future colonisation of the Space.

According to scientists it will take us at least 300 years to make Mars habitable and considering all our earthly dangers as well as the development of our civilisation we should start the process of adaptation now. Yet, turning our eyes and minds towards unknown places, it is worth to recall words of one of the heroes (Snaut) in “Solaris” by St.Lem: “We leave for the Space, ready for everything that means for loneliness, martyrdom and death. Through modesty we don’t say it aloud, but we think sometimes how splendid we are. Meanwhile, meanwhile we don’t want to gain the Space, we want only do extend the Earth to its limits.(...) We don’t know what to do with other worlds. One is enough and we already choke with it.” [5] In other words, for the human consciousness there is no difference between apprehension and appropriation. The strong anthropocentric tradition (reflected in the anthropic principle) reveals a deeper problem of the human condition: inability to go beyond our common human subjectivity. Nevertheless by acknowledging and understanding our boundaries we can extend our conceptual reach and “not choke” with our own world. If we manage to mature our humanity and thus our sustainability, we may succeed, despite the threat of a nuclear war, deadly pandemic and environmental collapse, in creating a truly planetary civilization [6] able to manage and share resources of its own planet; the civilization based on advanced cooperation and cultural convergence. That would be our first step towards stars. Then in thousands of years, as a stellar or even galaxy civilisation we may come across the Golden Record, our today’s message to distant civilisations, carried aboard Voyagers through the cosmic space and again listen to its immersive invocation: vibrating tones of J. Kepler’s Music of Spheres, the testimony of power of human creativity, imagination and visions.

PAINTING AS PROGRAMMING: CASEY REAS AND THE AESTHETICS OF GENERATIVE CODE

Meredith Hoy

This paper considers the work of Casey Reas, an artist whose output hovers between painting and computing. It proposes that the seemingly insurmountable division between the conceptual and the aesthetic is not absolute, and argues that Reas's practice, one that is fundamentally painterly but also tied to the specific functions made possible by a digital computer, offers an alternative to this artificial distinction.

In 1999, Jerusalem-born, New York based artist Daniel Rozin constructed a wooden mirror. In it, a heavy, octagonal wooden frame encases a grid of 830 square wooden lozenges, each of which is mounted on a small servomechanism. When a viewer approaches the mirror, each servomotor receives information relayed through a computer program from a hidden video camera, and mechanically angles the square toward or away from the overhead gallery lights. The degree to which each square is illuminated by or shaded from the external light source determines that square's visible gradation from light to dark. As each servomotor receives its real-time information about the figure standing before it, a grossly pixelated impression of the viewer's body coheres into visibility, accompanied by the faint clicking sounds of hundreds of scrabble pieces spilling over and against each other in a continuous loop.

Wooden Mirror is the first in a series of interactive installations fabricated from a variety of opaque, usually non-reflective materials, including wooden pegs, circles of laminated paper, woven fabric, and trash collected from the streets of New York city. In this series, Rozin announces that his aim is to explore the relationship between the analog and the digital, to "inflict digital order on a material that is as organic as it gets." But, this opens the question: in what features does the digital reveal itself? Why should we think of this piece as digital? Does it use digital technology to create an analog aesthetic experience? Or, does it employ analog technology to leave us with an aesthetic impression of the digital?

What we would expect to see in approaching a mirror, even a "fun-house" mirror, is a detailed if insubstantial image of ourselves generated by the refraction of light, no matter how distorted the results. When confronting *Wooden Mirror*, however, we cannot say the pixelated impression hovering before us is a "reflection," in the same manner as the reflections that appear in the silvered, glass mirrors to which we are so accustomed. Glass mirrors create a sense of continuity between the reflected world and the physical world in which the viewer stands.

Rozin's *Wooden Mirror*, on the other hand, compels us to gaze *at* instead of attempting to look *through* the wooden pixels as they sweep towards and away from the light. The opaque, and non-reflective lozenges render a granular likeness of the viewer, but in such a way that calls attention to the modular composition of the interface—the grid of wooden pixels—instead of effacing them in favor of an illusion of transparency. The particulate discreteness of the "mirror image" renders an indistinct, discontinuous impression, dismantling the possibility of a perfect virtualization by foregrounding the digital elements that give rise to the overall pattern.

Most often, it will be presumed that digital systems and electronic computers are equivalent because technologically speaking, electronic computers process information digitally. The digital is a term that

has become largely transparent—digital imaging, digital technology, digital sensors, all denote a technological milieu rather than an aesthetic one. However, instead of thinking of the digital as a technological category, in which an object is “digital” if it is a product of electronic computational processing, I am defining the digital as an aesthetic category, where “aesthetic” is deployed etymologically, to refer to the apprehension of features of an artifact that are available to sense perception. The digital then becomes a configurative and aesthetic modality rather than a technological one. Consequently, just because a picture is created using an electronic computer, whose underlying processes are computed digitally, it might not necessarily exhibit perceptibly digital features. And, contrastingly, an artifact that is made without computational processing might have digital features.

To more concretely illustrate what I’m saying, think, here, of each wooden square in *Wooden Mirror* as a “digit”—a discrete unit that, when combined into a schematic array, constitutes a digital screen. While this schema is comprised of physical, tactile materials, instead of electronic impulses, it is similar to a bit- or pixmapped computer screen, in which the pixels are spatially mapped, arranged in a regular pattern. The surface of Rozin’s so-called mirror is configured digitally, then, insofar as it is constructed of discrete, interchangeable, and articulate modules.

Even if it is a technological possibility that the pixel-like “modules” in Rozin’s mirrors could be further and further refined, to the point at which they could no longer be perceived by the human eye as individual units, and even if it is feasible that the materials deployed in these mirrors could mimic the color and texture of the person or object facing it, the more interesting question to me is why artists like Rozin choose *not* to pursue that technological teleology, and instead choose to foreground digital discreteness. Digital technology may be capable, notionally, of virtualizations that appear perfectly coextensive with the physical world. The number of calculations and speed at which they can be carried out by computers is potentially infinite, the upper limit determined only by the limitations of existing, and as we know, always dynamically changing memory storage and processing speeds. Nevertheless, it is important to ask what is achieved by making the digital sensorially apprehensible, by keeping it open as an aesthetic and analytic category worthy of conceptual and perceptual consideration.

I contend that giving aesthetic priority to the digital, instead of masking digital configuration, provokes viewers to consider how a variety of pictorial techniques and technologies involve digital or proto-digital processes at various stages from conception to realization, even if the final product obscures most indices of the technology used in the process of structuring the depiction. I argue that the phenomenon of digitality has been a mechanism undergirding representational technologies for far longer than electronic computers have existed. As such, the digital is not simply an art historical problem applicable to the study of contemporary art, but can be extended to a much broader consideration of how modules, matrices, and other digital techniques have shaped the norms and trajectories within various depictive modalities, from pictorialization to musical notation to cartography.

Rozin’s work is palpably discrete, programmatic, and digital, foregrounding the digital at the level of interface. But I will now turn to the “programmed paintings” of Casey Reas. As opposed to Rozin, Reas treats the digital as a primarily technological category, rather than an aesthetic one. As such, his work only occasionally and tentatively reveals the digital architectonics underlying his graphic schemas; most often his work is suffused with the analog properties of continuity, smoothness, and gestuality. I see Reas as a liminal figure, who operates in an indeterminate range of picture-making, one that is fundamentally tied to the specific functions made possible by a digital computer, but whose morphological structures are often dense, continuous, and remarkably and markedly painterly. Despite his thorough

investment in software-driven, computational art, Reas's work often obscures the discreteness of its underlying structure. The final output, in other words, is not heavily articulated in the manner of Rozin—Reas does not overtly embrace the pixel as a fundamental expressive unit. Rather, his works experiment with the aesthetic possibilities of algorithmic variation within a given visual system, a process that explores the limits of computation, but without necessarily offering up a digital aesthetic.

Let me briefly explain what I mean by analog aesthetic properties. Within the history of aesthetics it has been presumed that pictures would be a product of analog processes, and would therefore exhibit aesthetic features, which include continuity, smoothness, and perceptual ambiguity. The analog picture is irreducible, both on the level of form and content, to a distinct quantitatively assessed set of values.

The digital, on the other hand, emerges from a very different structural logic; digital composition is inherently discrete, schematic, metric, and modular. The classic example given by philosopher Nelson Goodman in 1976 to differentiate analog from digital inscriptions are the morphologically similar but semantically distinct illustrations of an EKG and a painting by the 19th century Japanese "floating world" artist Hokusai. [1] In the Hokusai painting, exemplary of analog values, every linear modulation, every increase in pressure or thickness of ink potentially affords a new layer of meaning. The EKG, by contrast, exemplifies a digital system, in which only the abscissas and ordinates bear meaning but the lines connecting them are insignificant. So, despite the morphological similarity between the two depictions, they function very differently.

Information is, of course, processed digitally in today's electronic computers, but the digital as an analytic and perceptual category can be disaggregated from the technical specificities of today's hardware and software. Rather, the digital refers to a particular configurative schema—to a state in which materials or signals operate and are operated upon as discrete states, as distinct from the continuous variation of the analog. Digital symbol systems may appear in the form of pixels, but may also manifest in a variety of other mark-making practices, such as points on a graph, in which a unit of measure has been assigned and outside of which no indeterminate state can be registered.

If Reas's use of digital technology is haunted by the spectre of analog painting practices, by a desire for the spontaneity and gestural contact that is traditionally associated with painting, this tension that arises in his work makes him an ideal springboard from which to see how the analytic category of the "digital" can, and should be disaggregated from electronic-computational machines. His work demonstrates how artists can utilize computational technology in a multitude of ways—to highlight the properties of digital graphic composition by foregrounding pixels or other structural building blocks, or to occlude the picture's digital infrastructure, leaving only indirect clues, or none at all, to its digital ontology.

It is within the architecture configured by the strict causal chain of computational logic that the oscillatory movement between digital and analog becomes evident in Reas's work. For example, Reas's series *Tissue*, beginning in 2002, layers fragile, transparent webs of spindly lines, creating dense, continuous and replete painterly surfaces, which would seem to position his work at odds with the constitutive features of digital aesthetics as demonstrated in *Wooden Mirror*. The lines themselves are generated by the movements across the screen of small bots or vehicles that leave trails of line and color behind them. The point I want to emphasize here is that while the technical, procedural and programmatic constraints of computers make them unable to process or deal in ambiguity, *Tissue* mobilizes the programmatic logic of computation towards an ambiguous end.

The characteristics visible in *Tissue* do not appear to be digital in the sense I am using it. However, the elements that produce the analog, painterly, ambiguous surfaces in these works turn out *not* index the gestural immediacy implied in the act of drawing, as we may have thought. Even though the surface appears to be aesthetically analog, it is in fact a set of digital elements drive the graphic output of the piece. As I have indicated, the lines extending across the screen or the print are created by digital “vehicles.” These vehicles mimic mechanical sensors in neuroanatomist Valentino Braitenburg’s studies of nervous systems in the 1980’s. In a different version of *Tissue*, an interactive, CD-ROM version of the piece involving touch and motion sensitive technology allows users to move the “dots” with their fingers, changing their trajectory and thus the visible structure of the composition. As such, the two versions—print and interactive installation—reveal the digital to differing degrees, the print concealing it, the interactive installation making it accessible to perception and interaction.

In an electrocardiogram, only the ordinates and abscissas are informationally relevant—the lines connecting them are insignificant. *Tissue*, on the other hand, privileges the connecting lines: what would be, in a notational system like the EKG, secondary “information.” What the viewer observes, instead of the digital units themselves, as in the case of *Wooden Mirror*, are the tracelines extending behind the elements, similar to the line of frozen vapor trailing an airplane in the sky. In a time-based version of the piece, after a period of scrutinizing the lines as they loop and intersect in seemingly random patterns across the screen, the intently watchful viewer might glean relationships between elements, and even potentially their position on the screen. We might think, then, of this moment of revelation as an instance of the digital furtively showing itself, coming into a partial visibility, but remaining camouflaged by the analog. Rather than directly seeing the simulated mechanisms, as in the see-sawing movement of Rozin’s wooden pixels, we gather their information second-hand. We can guess at their level of activity and the length of their simulated lifespan as drawing agents from the complex curvatures of the lines and the density of their entanglement. These knotted skeins become the sensorially apprehensible effect of the setting-into-motion of a digital system. What we have before us is a painterly, seemingly analog visual world that is actually a visualization of the byproducts of a digital system in the act of calculation and computation, but it is not itself aesthetically digital. This is an area in which a potential divide between “computational” aesthetics and “digital” aesthetics becomes visible. The system operates computationally, and perhaps we could classify the continuously unfolding loops of multi-colored lines as exhibiting a computational aesthetic insofar as we are watching the graphic output of computational processing proliferate before our eyes. But the “digital” stubbornly conceals itself within the tangle of lines.

Reas’s works after 2004, which he calls “Processes,” begin to allow the digital literally to parallel the analog aesthetic exhibited in *Tissue*. They exhibit a tri-partite structure, in which natural language “instructions,” in homage to LeWitt, are accompanied by a divided screen. In *Process 18*, the right screen displays a simplified digital schema of the underlying processes of the generative software. Here, a skeletal array of short white lines against a black screen reveals the “mechanism” determining the behavior of individual parts as they touch, collide, and rebound. In *Process 18* the right screen gives up the “trick” or the “game” or the “conceptual undergirding” of the work precisely by showcasing the schematic, digital structure that underlies the painterly swaths on the left screen.

On the left screen the mechanistic structural elements—the skeletal backbones—are erased, as the orthogonals and transversals disappear from a perspective painting, leaving the surface effects—here, curved, layered lines, of varying degrees of transparency and various degrees of saturation on a grayscale—available to sensory apprehension. In contrast to the austere structuralism of the right hand screen, then, its neighbor on the left reveals the more “painterly” aspect of Reas’s multi-layered process

compendium, offering up an abstract, gestural surface that, minus the textures, is more reminiscent of Jackson Pollock's Action Painting than Rozin's heavily digitized *Wooden Mirror*. However, these works are more "digital" than the others I have discussed with you today because the digital and analog surfaces are placed in parallel. In *Process 18* the side-by-side placement of the screens does *not* erect a hierarchy in which the analog is granted final pride of place.

In *Tissue*, digital mechanisms, such as a line of a specific number of pixels, become drawing "agents," but in the act of drawing, they obscure their digitality, rendering the digital, in Reas's practice, a technological rather than an aesthetic category. In this sense, Reas *reverses* the schema of Rozin's *Wooden Mirror*. There, the motion of the servomotors is perceptually analog—their movements and adjustments register as continuously correlated to the position of the viewer, just as a needle in a pressure gauge rises and falls smoothly, as a direct effect of the modulations in the physical quantity of pressure in the gauge. It is only the outermost layer of the interface—the array of discrete, modular wooden lozenges—that defines Rozin's mirror as *aesthetically* digital. In *Tissue*, on the other hand, the computationally simulated bots mimicking Braitenberg's neural motors are digital—they are registered by the system in terms of their position at any given moment. But whereas the bot's *position* is digital—it can only occupy one encoded position at a time, the visible output of the system is continuous, fluid, and aesthetically analog. In the end, Reas's work does not evidence two entirely separate strains. Instead, these two impulses swirl playfully around one another in a noisy feedback loop. They are each practices built on digital platforms, but shot through with the spectre of the analog.

To return to my opening example, Daniel Rozin in *Wooden Mirror* formulates a visual (graphical) proposition in which the "digital" becomes a sensed and experiential, instead of a technological category. Here I am placing the digital in an expanded field, so that it is a mechanism, a process, and a constructive method that operates well beyond the boundaries of computational technology. Once digitality is disaggregated from contemporary electronic computers, it becomes a category that can be used to address works of art, techniques and technologies that may speak in a different language than and thus require a different interpretive framework than pictures and artifacts configured through analog processes.

What I call the digital is a mode of visual understanding that has appeared at other times under other names. It speaks to the replicability of the pointillist dot, and to the simulated matrix of perspective. Here, the digital ceases to be a highly technical term relevant only in contemporary discourse, but becomes an art historical project about making connections. This is not to enforce *congruence* between all digital, proto-digital, and quasi-digital systems—I do not claim that perspective, pointillism, op-art, and contemporary computational artworks are reducible to historical, cultural, and formal equivalence. Instead, I bring out features of these works that interface with my notion of the digital in complex and potentially idiosyncratic ways. My question of whether the "look and feel" of digital media is correlated to the appearance of individuated "digits" within pictorial structure is ultimately not merely a formal, but also a social, philosophical, and art historical problem, which seeks to discover how an evaluation of digital composition might add a new narrative layer to the long art-historical discussion about how and why pictures "mean," and what they say about a given culture in a given historical moment.

VIRTUAL RESISTANCE: A GENEALOGY OF DIGITAL ABSTRACTION

MEREDITH HOY

According to one narrative, an evolutionary trajectory for computer graphics begins at rudimentary figures and progresses towards visualizations of a world whose properties mirror our own. But there is a tradition of computational abstraction that renders visual equivalents of abstract mathematical calculations. This paper considers whether computational abstraction fits a modernist narrative or whether it envisions a new call to order.

According to one narrative, the history of computer graphic imaging has privileged verisimilitude, in which a virtual image imitates optical reality as faithfully as possible. This account posits an evolutionary trajectory for computer graphics beginning at pixel-based figures and progressing towards rich visualizations of a world whose properties mirror our own. This history may hide the fact that this virtual world is often visualized as if it were captured by a camera; the camera-based image is simulated by encoding a mathematical model of a picture as it would appear through a lens, with a specific field of view and focal length.^[i] Computationally generated pictures often analogize the visual qualities of a world seen through a camera lens, and would seem to tend towards the particular qualities of virtuality, and the visual distortions, produced by a camera.

But there is a tradition of computational abstraction that revels in the facility of the computer to render visual equivalents of abstract mathematical calculations. Such screen-based abstractions generate imagery based on formulae for physical forces such as gravity. Painterly compositions emerge as a result of inputting random values into an algorithm encoding change over time. This paper assesses whether there are a set of principles with which computationally based abstractions are concerned, and what kind of “world” is imagined through this algorithmically generated visual model. Taking into account the history of abstraction in modern art, it considers whether computational abstraction fits into a modernist narrative or whether it envisions a new call to order distinct from that set forth by 20th century modernist movements.

The aesthetic of mimetic virtuality demonstrated by graphics imitating a camera can be distinguished from an aesthetic of computational abstraction by the latter’s typical foregrounding of discrete values mirrored in the structure of the picture. A digital image is defined by its discrete composition out of distinct, interchangeable units. This is most easily recognized in the formal properties of the pixel, but can also be conceptualized in a more theoretical manner, as in Nelson Goodman’s formulation, according to which “to be digital a system must not be merely discontinuous but *differentiated* throughout, syntactically and semantically.”^[ii] This formulation adds another dimension to the theory of picturing in general, one in which analog and digital aesthetics can be formulated and evaluated as distinct categories. There is also an aesthetic trajectory that bridges the gap between the two modes of analog and digital by examining the structural features underlying a given representational system through strategies of abstraction.

One exploration into the mechanics of recorded moving images occurs in the phenomenon of Structural film that emerges in the 1960’s. Deploying such strategies as loop printing, rephotography off the screen, the flicker effect, and fixed camera position, structural film is “a cinema of structure in which the

shape of the whole film is predetermined and simplified....and what content it has is minimal and subsidiary to the outline.”^[iii] Structural film unfolds algorithmically, according to a predetermined system, which provides the rules according to which the film proceeds. Structural film is invested in uncovering the material infrastructure behind the continuous motion we come to associate with cinematic technology. It also, crucially, often favors abstraction, for example in the films of Paul Sharits, as a convenient mode of exploring film technology.

To understand what kind of images or objects will be most likely produced within a particular technological milieu, it is imperative to consider the facilities of that technology—the ways its affordances and constraints will, alongside creative decision-making on the part of the artist and other factors (such as cultural norms), dictate the types of forms that will be produced by that technology. While most traditional narrative film attempts to make the medium transparent through such techniques as suture, in which the editing and other elements of the cinematic apparatus are suppressed, structural film examines the material qualities of the filmic medium. Like conceptual art, in which the visual qualities of the final product are secondary to the idea underlying and driving its production, structural film reveals the mechanics of film, or the “idea” of film itself. Structural film is, therefore, “cinema of the mind rather than the eye.”^[iv] Often, for example, structural film will use rephotography to emphasize the graininess and flatness of the image, disrupting the reality effect or impression of virtuality that might otherwise occur.^[v]

Alongside structural film, early computer animation utilized the particular visual characteristics of computationally generated imagery to reveal what I have called a digital aesthetic based on discreteness and the use of an interchangeable module as the fundamental unit or building block with which computational pictures are constructed. I suggested above that while the history of analog picturing privileges qualities such as smoothness, continuity, and indiscernability of internal parts, the “digital”, recognized qualitatively as having its own particular visual characteristics, reveals its constitutive discreteness, its ability to calculate and generate patterns based on the computation of individual values. This often results in the production of an abstract visual field and the rejection of mimesis in favor of a direct interrogation of systemic principles.

Examples of early deployment of computational strategies for the production of “art” emerge in various media, including film. Stan Vanderbeek, Jordan Belson, and John and James Whitney are among the most important producers of abstract film that utilizes computation—a phenomenon that Gene Youngblood calls “cybernetic cinema.”^[vi] Cybernetic cinema, for Youngblood, is an approach to the production of moving images that privileges not merely a photographic capture of the external world, but situates itself in terms of the relationship between humans and technology, or more precisely, as Zabet Patterson has articulated, “under the auspices of the human-machine feedback loop.”^[vii]

The link between abstraction and technology is observable throughout the history of modernism. The rise of modernism is concomitant to the rise of industrial and reproductive technologies, and as such, technology itself becomes the subject of art. Modernism is also recognized as bringing about the advent of abstraction in the visual arts, and while technology and abstraction might seem at first glance to be unrelated, or to follow divergent principles, they are in fact inextricably entwined. Abstraction begins to turn toward the look of the technological in numerous instances, as in the proto-computational, pixelated forms of Victor Vasarely’s Op-Art and in the synthesized mandalas of John and James Whitney.

Meditations on the expansive effects of technology on the horizons of visual representation in modernist art practice are nearly endemic. Futurism gives up “meat” (the representation of human figures,

especially the nude, in the history of Western art) in favor of creating a visual universe that celebrates the beauty of speed, simultaneity, and the clang of machinery, all phenomena directly attributable to the compressions of time and space wrought by new technologies.^[viii] Futurism does not only depict machinery, but it also explores the way in which technology provides a new visual and perceptual experience of the world—it examines not only what technology can do, but also the ramifications of that technology on our consciousness, for example the shrinking of time and space that occurs with the invention of mechanisms for fast transit, such as the automobile.

But modernism has also been characterized by a concern with the spiritual, with purity, often achieved by the reduction of form to its most basic elements. Total abstraction, then, with its aims towards a spiritual universalism, would seem to be opposed to a technological worldview focused on functional forms. But as RL Rutsky has pointed out, a formalism oriented towards the *look* of technology in the end abstracts the technological from functionalism, so that the technological becomes a representational trope that speaks toward an overall world view rather than a direct portrait of specific technological devices. Heidegger has argued that “the essence of technology is by no means anything technological”—technology is not revealed in particular objects, but in a turn toward a technological way of thinking, in the way that new technologies reveal aspects of the world to us.^[ix]

Ultimately, technology and spiritualism become deeply imbricated. The theosophic foundations of De Stijl, led by Mondrian and Van Doesburg, merge spiritualism and functionalism. Abstraction is posed as the antithesis of nature and the natural—it is “functional” and ordered as opposed to the disorder of the natural, and is of the spirit, which is also separate from nature. Universalism and abstraction are deeply imbricated with one another, united in their opposition to nature, as is evident visually in the precise geometrical angles and forms of Mondrian’s and Van Doesburg’s painting. These geometries are linked to modern urban life; the “genuinely Modern artist sees the metropolis as abstract living converted into form.”^[x] Moreover, modern living is characterized by the machine, and machines are, counterintuitively, connected with spirituality; “the machine is, par excellence, a phenomenon of spiritual discipline.”^[xi] Abstraction, now associated with the functionality of the machine, in turn becomes a function of the machine, as is visible in the films of Vanderbeek, the Whitneys, and later generative computational “drawing.” (And it is notable that the Whitneys state an alliance with Mondrian and his view that abstraction attains a “truer” reality.^[xii]) The images we see unfolding on the screen can be read, alternately, as simulacra of computational functions or as indexical traces of the same. This undoes the opposition between autonomous generative grammar and indexicality, given that generative grammar can be seen as leaving its own imprint in filmic form.

“Function” can have various meanings. Computers are functional in their ability to create a model of the world by numerically calculating and graphically representing calculable data. This utilitarian view of function can be set against the theory of abstraction, as proposed by De Stijl or the Suprematists, in which abstraction provides an indirect model for universal social freedom. Both approaches to abstraction have a distinctly utopian bent, the former imagining a perfect simulation of the world attainable through the powers of computational machines, the latter championing the capacity of abstraction to produce social harmony. The two poles of realism and abstraction, therefore, eventually converge in their utopian teleology.

Film and video are most often associated with principles of realism—they are technologies whose particular affordances lead toward mimesis. As a reproductive technology, film might be thought to have the capacity to reproduce the world in much of its fullness; film both reproduces the world and is itself reproducible. But cinematic trends toward abstraction have coexisted with traditional narrative film, as

we see in early experiments with abstraction such as Duchamp's *Anemic Cinema*. Abstract, generative computational video takes filmic abstraction even further, going beyond abstract cinema's exploitation of shape and line to offer a visualization of often *invisible* forces such as push and pull at various rates. Mark J. Stock's simulations, for example, combine individual elements exhibiting simple behaviors into "complex galaxies" of abstract, moving forms whose rules for development and change are governed by a mathematical system with distinct parameters. According to Stock, these fluid visual landscapes reveal "the natural origin of their rules. This is the way of computational science: to break complex, real problems up into many smaller and easily solvable problems such that the ensemble predicts the behavior of the real system."^[xiii]

One can go one step further to claim not only that technology and abstraction have been linked from modernism forward, but that there is a particular view of technology and technological operations that foregrounds a computation and calculation. This computational order privileges systems that deploy numerical values or other non-numerical forms of calculation (any kind of "system") to produce its results, in this case the visual field of representation. The work of Frieder Nake and George Nees presented a mode of artmaking in which the artist's unique capacity to manifest the beautiful is supplanted by the computer, leading to a rationalization of beauty, a notion of beauty as emanating from programmatic schemas. Amongst early computer artists, including Nake and Nees, there was no small anxiety about this notion of programmed beauty—could the artificial generate an authentic work of art, or would the experience of beauty be authentic? Eventually, the most likely conclusion to be drawn is that what is being accomplished is not merely the imitation of pre-existing modes of artmaking, but that something new is being introduced: an art that foregrounds the abstract structures produced through programming. Machine-realized art moves us away from the virtuosity of the artist's hand, the grand designs of her mind. Computationally executed art comes as close as possible to completing this circuit. In so doing, it envisions a world of values and forces, understood better in terms of computational efficacy than mimetic reflection.

A brief look at the history of computing reveals the development of a philosophical trend in which mathematics and systems theory play an increasingly prominent role in theories of knowledge, human behavior, and even art. Researchers such as Turing, Von Neumann, Shannon and Weaver, and Wiener postulate that phenomena can be accounted for in terms of logical operations. "Rationalization" in representational terms consists of analyzing and reducing form to its most basic elements, whether this is the simplified form of the square or the breakdown of the world into data.^[xiv] Likewise, abstraction is a process of stripping down worldly phenomena into its most elemental or essential forms. In this way, abstraction can be viewed in terms of rationalization, as a mode of quantification of form into a series of operations. Thus, abstraction can be both spiritual, in its search for essences, and procedural, in its breaking of matter into its constituent operative parts.

George David Birkhoff, the American mathematician, proposed that the beautiful is a function of order, so that something with the greatest amount of order and the least amount of complexity is the most beautiful.^[xv] This parallels the theories of abstraction in the history of modern art that have attempted to systematize visual signs through the reduction of elements such as shape and color to their most basic forms. As I have suggested, abstraction, for visual artists including Malevich and Kandinsky, approaches spiritual purity.

Information aesthetics are often associated with generative art, which has been defined as art that deploys a system, such as a computer program, that is "set into motion with some degree of autonomy contributing to or resulting in a completed work of art."^[xvi] A work that is designed and carried out

using a pre-determined system that unfolds with or without the intervention of the artist's hand does not necessarily but will often demonstrate the aesthetic or formal properties of that system in a self-reflexive manner. Thus, the visual world built by these systems is one that replaces mimesis with an exploration of repetition, transformation, and parametrization.

Looking at Mark J. Stock's 2009 *Rising*, it becomes apparent that because informatic and generative art is concerned primarily with the principles and system with which it is constructed, it will be more likely to remain unconcerned with verisimilitude. Viewed from one angle, generative art emerges from a lineage of proceduralist aesthetics, wherein "inanimate accuracy" is substituted for "human touch."^[xvii] Generative graphics reveal a field of operations whose principles of change—growth and decay, for example—are given by certain encoded parameters that exist and unfold apart from the artist's decision-making process. Because it is computational, the system necessitates fragmentation, the existence of parts that can be set into motion by the program. As a visual form, generative art is certainly concerned with the aesthetic qualities of its product, but the aesthetics are defined by the interactions between parts and the emergent qualities that develop as a result of this interaction.

Lev Manovich has defined the aesthetic quality of computational art in terms of an aesthetics of complexity,^[xviii] which exists in contradistinction to the simplified forms of earlier 20th century modernisms, such as the extremely reduced formal vocabulary and palette of the Russian avant-garde, and particularly Suprematism, in which Malevich "in 1913, trying desperately to liberate art from the ballast of the representational world...took refuge in the square form."^[xix]

I would define computational aesthetics not so much in terms of complexity, but consider instead the aesthetic ramifications of the computer's ability to carry out rapid, repetitive calculation and to build structures out of discrete, interchangeable units. Looking at Gursky's *99 Cent* or Jennifer Steinkamp's 2008 *Daisy Bell*, we can observe instead an aesthetics of repetition, a sense of an indefinitely extendable universe of discrete elements arbitrarily cut off by the boundary of the screen, the mechanism by which this computational universe is made visible.

This repetitive calculation can be used either to mask or to highlight a picture's computational underpinnings, to build a dense, virtualized simulation or to emphasize the discrete, numerical infrastructure of the image. Artists such as Jim Campbell, who in his *Ambiguous Icons* series reduces moving figures to broad, highly unresolved silhouettes by filtering them through a grid of LEDs, choose to foreground the fact that what ultimately appears as a picture on a screen begins as a chain of abstract data. Campbell abstracts photographically captured imagery using discreteness and low resolution to interrogate the notion that computational imagery must always produce a seamless virtualization of a three dimensional world.

What I have shown in the preceding arguments is the way in which theories of abstraction have united with theories of modern technology, from the mechanical to the computational, to produce a particular mode of representation: technological abstraction. Technological abstraction has a lineage that extends beyond the advent of computers; after the invention of modern computers, it is evident in work produced using mechanical, analog computers and later, digital computers. These works deploy the same machines used to generate immersive virtual worlds, but utilize that technology towards very different ends. We should not suppose that computational abstraction emerges simply because computers were not yet able to construct virtual worlds, but rather that it arises alongside a fascination with a computa-

tional universe, governed by the same physical rules as the human body, but adhering to a different perceptual order, one which favors pure relations, patterns of data, and elemental forces, and into which we are ushered via the screen, with its array of points of pure light and proliferation of digital units.

INVESTIGATING THE DIGITAL SUBLIME THROUGH PHOTOGRAPHERS' VIEWS OF REALITY: A CASE STUDY OF NATHAN BAKER'S OCCUPATION PROJECT

YI-HUI HUANG

The digital sublime refers to digital-composite photography that presents the existence of something unrepresentable. Dissatisfied with the representation of the outer world, sublime photographers are compelled to create personal versions of the world. To better understand these photographs, I propose that we investigate the artist's views of reality. This paper cites Nathan Baker's project *Occupations* as an example.

Introduction

The concept of the "sublime" has been discussed by a few philosophers. According to German philosopher Immanuel Kant (1724–1804), the sublime refers to something "absolutely great" [1], such as the vast Saharan desert or an earth quake, that surpasses one's ability to comprehend with one's reason. The sublime brings a mixture of anxiety and pleasure to those experiencing it: anxiety from the conflict between reason and imagination, and pleasure from the awareness of the supremacy of human reason. While Kant focuses on sublime nature, French philosopher Jean-Francois Lyotard (1924–1998) concentrates on sublime art, such as avant-garde art, which presents "the existence of something unrepresentable" [2] and that confronts us with the limits of our ability to reduce the world to rational concepts.

More recently, the term "sublime" was used to indicate a new type of photography. With the rapid advancement of technology in the photographic industry, more photographers, such as Jeff Wall, Pedro Meyer, Barry Frylender, and Loretta Lux, have been relying on digital facilities and embracing the style of digital-composite photographs. Using computers to combine pieces of images, digital-composite photography requires a new method of production and renders a matchless look – a sophisticated fabrication, a perfect and clean composition, a maximum color saturation, a multiple-point perspective, and stunning or newfangled content – which is often referred to as the "digital sublime" [3].

This paper investigates what "unrepresentable" entities the digital sublime attempts to present. Dissatisfied with the representation of the outer world that can be easily accomplished by pressing a single shutter button, photographers who painstakingly synthesize images together to create the digital sublime seem to be compelled to create personal versions of the world, which may be closer to the beliefs through which they interpret and interact with the world.

To gain a better understanding of these photographers' digital sublime photographs, I investigate the photographer's worldview, or what s/he values as knowledge. As contemporary architectural theorist Mark Gelernter (1995) suggests, knowledge is the foundation of one's intention, ideas, and thus, forms of artwork [4]. If we understand how a photographer sees the world, we can have a better idea about the principles that guide his or her artmaking. A more approachable way to inquire into a digital photographer's knowledge is to ask about his or her view of reality [5] with questions such as "What is your definition of reality?" "What notion of reality do you represent in your photographs?" and "How do you visualize your reality in photographs?" After knowing their layers of reality, the deepest and the most

sophisticated layer can be considered as their knowledge, which may explain the “unpresentable” substance presented to viewers.

As an example of how we can understand a body of digital sublime work, the following section cites the photographic project *Occupation* of Nathan Baker. The discussion of Baker and his work is primarily based on an interview I conducted with him in December 2006 in his studio. In addition, I referred to Baker’s artist’s statement as well as consulting other critics’ evaluation of his work.

Herein, I first introduce Baker’s process of photographic creation, including his initial feelings, thoughts, ideas, and finally, the actual production. I then relate his definition of reality, and strategies he employs to visualize reality in his photographs. Next, I interpret Baker’s multiple layers of reality and cite suitable theory, realism, to explicate her work. Last, I conclude with the knowledge provided by Baker’s photographs, from which we can gain a better understanding of his art.

Baker’s Occupation Project

In his project entitled *Occupation*, Nathan Baker, a Chicago-based artist, produces composite photographs that express the labor one puts into one’s job. By condensing various tasks required by a job into a single frame, Baker evokes “the frenzied tedium of a wide variety of occupations and the intensity of effort that people put into them” [6]. The *Occupation* project consists of twenty photographs, each presenting one job at a workplace, and hence describing twenty occupations ranging from scooter repairer, house painter, to hotel housekeeper.

Baker explains that his initial idea to produce *Occupation* was from a negative perspective. It was later, from viewers’ responses concerning the humanity shown in the photographs, that he started to look at the occupations positively. Coming from a lower-income working-class family where money was always an issue, Baker learned that jobs have occupied most people’s lives, and that people devote incredible amounts of energy, effort, and time only to benefit other people. In turn, what they gain is mostly contempt or mocking of their “circus-like bodily performances” [7]. However, viewers see this project differently: esteemed humanity outweighs other messages. Therefore, intentionally or unintentionally, Baker demonstrates the tension between the disgraceful and dignified natures of a job—its skills provoke scorn, though they deserve respect.

Baker articulates his production of these images. All of the twenty occupations are working-class, which reflects a lot of labor and specific manual skills. The stationary camera is usually positioned higher to render a full view of the whole space as well as the details of every task. In addition, the faces of the workers are intentionally sheltered or side-viewed to avoid viewers’ quick recognition of the fact that it is the same person at work in the final images. This strategy prevents Baker’s seamless digital composites from being immediately read as unnatural Photo-shop collages. His ultimate purpose in de-emphasizing the Photoshop techniques is to make his photographs documentary-like.

To improve the believability of his documentary, Baker utilizes photographer Robert Frank’s (b. 1924) “filmic style of photography” [7], where photographs are composed in a seemingly casual way by intentionally leaving some part out-of-focus. This style imitates the visual habit of glimpsing as if one is looking at the actual scene. By implementing this filmic strategy, Baker invites viewers to enter the scene, or

makes them feel that they are present in the situation where the photographs were taken. In Baker's opinion, the more viewers can bring themselves to the scenario, the more believable the photograph is. For example, Baker incorporates a blurred arm in the left side of the frame in *Casino Boat Engine Room* to create an illusion that viewers are actually present in this space and watching these workers.

Despite embracing Frank's strategy of filmic documentary, Baker says that a single shot was not sufficient for him to describe something thoroughly. He then realized that when putting together all these single shots of the same person digitally, he was able to communicate more facts about the job so as to achieve "a real representation" of it. Because each shot was taken in real time and in a real space, the final images are still considered documentary. However, in Baker's terminology they are more than traditional documentary; they are comprehensive documentary. Baker has described each occupation as fully as he can within the framework of the medium of photography, and since he directs people to perform the tasks of their jobs, he also calls his project "directorial documentary" [7].

Baker tends to investigate a subject by showing concrete objects associated with the subject. For example, in his previous project *Tangible Mediation*, he showed an individual and an object the individual chose in each photograph. By closing the eyes of each individual, he directed viewers to see the objects first, and then ponder the relationship between the object and the subject in order to sketch the identity of the subject. For Baker, objects are "mediators that provide both personal and societal representations of individual identity" [7]. In other words, in Baker's view, a tangible object from the outer world serves as an important clue to understanding what is going on in a person's mind.

Baker succinctly defines his view of reality: "My definition of reality is one's experience, which is composed of a physical component and an intellectual component. Those two things compose one reality" [7]. According to Baker, the physical component comes from his five senses, and the intellectual component indicates his thought or idea that responds to the sensory stimulation. Following this criterion, Baker's *Occupations* represents a reality for him. On the one hand, it presents his experience of actually taking pictures of these people. On the other, it demonstrates his ideas of comprehensive documentary, which thoroughly describe twenty occupations.

Baker also asserts that his photographs carry multiple types of reality to viewers. The first type is the physical reality of the pictures itself. The second type presents each figure performing in real time and in a real place and was recorded as snapshots. The third type, even more real than the second, shows a multitude of figures co-existing in an invented space, and contains fuller information. The last type is the metaphoric references or visual connotation that makes viewers think about the ideas behind the pictures, or different mental places that viewers go individually.

Theoretical Understanding of Baker's Work

Based on Baker's assertion that two components constitute his reality, his view of reality can be explained as two-layered. The first layer comes from the five senses, and the second is the idea or thought provoked by the sensory. Thus for Baker, coming from the most sophisticated layer of reality, knowledge is ideas derived from sensory experiences, and such a view renders Baker a realist.

According to British realist philosopher John Locke (1632-1704), objects exist in the external world independent of the mind. In some circumstances, when these objects act upon the senses, a stimulus is transmitted from the senses through the nervous system, and eventually gives rise to a mental

process—the conscious perception of the object [8]. The idea of the object thus derives from the faculty of understanding which abstracts, systematizes, orders, and abbreviates the data of sense. Locke also explains that the mind is like a camera; when it is passively acted upon by external objects and receives stimulation, the mind, or the camera, registers ideas that reflect and resemble these objects. For Baker, the sensory and ideas rely on each other and are indispensable components in the formation of his knowledge.

Baker's ordainment of the four types of reality given by his photographs can actually be categorized into his two layers of reality. The first and the second, respectively the physical reality of the picture itself and the fact that each figure exists in front of the camera in real time and space, are physical realities where viewers can touch and see their existence. The third, where multiple figures coexist in an impossible plane, comes from Baker's idea, which results from solving the problem of how to bring more information into photographs to provide a complete illustration of his view. Finally, the fourth is viewers' mental states or individual interpretations of images. Echoing contemporary philosopher Kendall Walton's (1984) assertion of "transparent photographs [9]," Baker contends that when viewers look at his photographs, they not only see the pictures themselves, but by seeing through photographs, they literally see figures photographed. In addition, viewers capture Baker's creative idea of putting figures all together, as well as giving rise to their own meaning about the photographs.

Baker's *Occupation* corresponds to Aristotle's (384 BC – 322 BC) description of mimetic artwork, which is considered the first theorization of realist art. First of all, *Occupation* does not only represent the particular event of a person at work, but illustrates occupations in general, such as hotel housekeepers. Baker presents a normative idea of what an occupation *ought to be* from his own point of view.

Secondly, the basic components within the final images are acquired from the world; that is, they are all what one can observe with the naked eye. It meets Aristotle's emphasis on the use of the senses, and on the empirical observation yielding certain and clear knowledge of the world. In addition, Baker's attitude toward the subject matter is not fantasizing, disdainful, or criticizing, but is fairly and objectively displaying what a job consists of. Also, his manner of presentation is not prejudiced, distorted, or idealized, but is impartially describing what he sees about a job from his own perspective. In other words, the subject matter of people at work is the primary concern, while his judgmental expression is secondary.

Thirdly, an important criterion for Aristotle in art is the dispensability of form and content. Baker's strategy of repeating an identical person at work does not derive from a formal concern, but is crucial to the articulation of his idea: the tension between the complex skills an occupation can involve and the entertaining bodily performances an occupation requires. In Baker's view, his strategy also serves to describe an occupation fully by bringing in more information. This information does not come from Baker's subjective inner world, but is from his experience of interacting with the world. Alternatively put, for Baker, to describe something fully is to provide all that he can sense, and what an occupation means to him is comprised of what he can experience visually. Consequently, for example, a job is depicted by using thirty-six decisive moments, which are simultaneous form and content.

Lastly, similar to Aristotle's articulation that the intent of mimetic drama is to give pleasure, Baker urges viewers to contemplate pleasure from viewing his well-planned photographs. Condensing various bodily gestures at work, Baker highlights the amusement from watching circus-like performances. This pleasure requires viewers' cognitive operation of the mind. Viewers can understand this humor as long as in the real world they have ever seen similar presentations.

Baker's work is also subject to realist explorations in general, and hence provides realist knowledge. His comprehensive documentary stresses the resemblance of the representation in synthesized photographs to what, in his view, is actually happening in the real world. The verisimilitude of his depictions gives a vivid sensation of seeing those workers in everyday life. By arranging them realistically so as to make use of the believability of documentary photographs which dictate a real time and a real place, Baker's viewers tend to consider the workers as, indeed, being in front of the camera. However, what makes *Occupation* different from normal documentary is its more-than-usual amount of true information about what it depicts. This motivation of adding more factual and pertinent information has made *Occupation* realist [10]. Consequently, Baker's realist knowledge provided by his photographs dwell in the window on the world, which presents the likeness of what occupations really are. By including more data and keeping the combination seamless, Baker has polished the window itself so as to let it contain a richer view.

Baker's strategies to visualize occupations correspond to his realist worldview. Whether in *Tangible Mediation* or *Occupation*, his realist intention is to illustrate a person through objects around him or tasks he encounters. That is to say, what accounts for a person or an occupation is situated in the outer world. To understand a person, Baker resorts to an object the person picks; to know more about a job, he compacts a variety of tasks into photographs. Along the same vein, *Occupation* is composed of a culmination of multiple documentary photographs, which no doubt originated in the external world. After gathering components from the outer world in the form of documentary, it was Baker's faculty of understanding at work to systematize, abstract, and abbreviate data, and then generate the idea of multiple figures in one image. The final result is the comprehensive documentary which surpasses documentary's limitations, while preserving its nature. Influenced by but different from Robert Frank's filmic style, in which "the image seems boundless, not contained within the rectangle of the frame, but stretching beyond it," Baker's composite photograph is literally a film, which stretches beyond one single decisive moment and records the whole process of time and tasks associated with the job.

The directorial ingredients in *Occupation* do not interfere with its realist essence. In theorizing the directorial mode in photography, critic A.D. Coleman (1998) asserts that the directorial elements have played a part in a large number of documentary or straight photographs, including those of photographic image-makers who title themselves documentary champions. In *Occupation*, the authenticity of the original event is not an issue; rather, it is the general idea of what an occupation consists of that anchors the subject matter. Therefore, no matter how the scenes were constructed, how workers were directed to perform their skills, or how many pictures were condensed in a final image, Baker's realist perspective remains the same, where he acquires knowledge about occupations through his experiences and presents what he has observed with his senses to viewers, who then gain the same knowledge. All of the directorial efforts were made only to describe the given object or event fully, rather than to impose Baker's emotional impulse from his inner to alter the given knowledge from the outer world.

Conclusion and Implications

Investigating digital photographers' views of reality helps identify and clarify the valuable knowledge they communicate in their work. In Baker's sublime photographs, we can find two layers of reality: the sensory stimulation and his understanding of it. In *Occupation*, he exemplifies realism. The knowledge he provides to viewers and the "unpresentable" substance that his photographs try to present reflect his perspective of a detailed, true-information-laden, and believable representation of those occupations in the real world. By making his photographs resemble the world, Baker urges viewers to look into the

drama screened in paper film, and to contemplate the dignity and humor that transpire from the human figures.

Students of photography need a deeper understanding of the nature of digital-composite photography before they select it as the medium for expressing their ideas. In order to appreciate and teach about the digital sublime, photographic educators need to be aware that the digital composite may deliver a variety of aesthetics and knowledge, which may encompass modernism and postmodernism so as to incorporate pedagogies that address both the appreciation of fine arts and the critique of visual culture in classrooms.

DIGITAL RE-PRESENTATION AND SIMULACRUM IN AUGMENTED REALITY

Yu-Hsiung Huang, Tsun-Hung Tsai & Su-CHu Hsu

This paper presents new definitions of digital re-presentation, simulacrum and pleasurable design for augmented reality (AR). We use this definition to survey some recent digital artworks. We move from AR to digital re-presentation, building on Baudrillard's ideas. Digital information processing can amplify AR, allowing virtual objects and virtual reality to join together. It makes a simulacrum world in which we can take pleasure in immersing.

Fig. 4. The Jew of Malta Opera (2002) Fig. 5. Immersive Chinese Painting-The Ten Gibbons (2005)*

Examples of Digital Re-presentation in Augmented Reality

This section gives examples of the application of digital re-presentation and augmented reality in digital art. In each of the augmented reality system described below, an object acts as a "marker" for projecting or recording information for the augmented reality.

- **Augmented Reality in Interactive Entertainment**

Art Digital entertainment art contains the potential for teaching and pleasure. Artist Taisuke Murakami's *Contact Water* was presented at SIGGRAPH in 2001. [3] Participants donned head-mounted displays and hand sensors, and were able to virtually take a miniature dolphin out of a central pool, and pass it to other participants (Fig. 1). This interaction was both fun and an example of augmented reality. A digital re-presentation of each dolphin was projected onto the hands (marker) of participants. The participants were able to use their hands to transfer the virtual dolphin re-presentation to other viewer's hands, creating a sensation of virtual physical touch.

- **Augmented Reality in Interactive Story Animation** Augmented reality can advance animation from passive to active participation. Tokyo University's *Tablescope Plus* [4] used augmented reality in interactive story animation (Fig. 2). This work projects animated characters and scenery onto real objects marked on a tabletop display, using a camera which can recognize objects (markers) on the tabletop display. When the participant puts marked objects close to each other, the characters react to each other, as if in a movie. The user's operation is the key step in the digital re-presentation of these cartoon stories. By creating conversation among selected object, *Tablescope Plus* enhances the sense of exemplary viewers' involvement, and shows the fun in the stories. The audience can enjoy the story animation and have intellectual and emotional pleasure.
- **Augmented Reality in Interactive Visual Art**
Visual art transmits the artist's idea visual impact. Interactive effects can improve art works and deepen the impression of the audience. Clara Boj and Diego Diaz's *AR Magic System* [5,6] records participants' faces (markers) and exchanges the faces with different bodies in a screen projection (See the URL at reference [6] for an image from this artwork.) This "digital re-presentation" causes a strong visual impact and a funny confusion of identity exchange.
- **Augmented Reality in Interactive Sound Art**
Sergi Jordà at Universitat Pompeu Fabra used augmented reality in his 2006 *ReactTable*. [7] *ReactTable* is a collaborative musical instrument. People place different blocks (markers) on the table to control musical loops and filters (Fig. 3). These interactive sonic displays allow participants to feel relaxed and enjoy an interactive musical performance of the digital re-presentation.
- **Augmented Reality in Interactive Opera**
Performance Augmented reality has begun to be applied to interactive performances. Germany's ART+COM used augmented reality in the stage setting and costume design of the opera *The Jew of Malta* premiered at the Opera Biennale Munich in 2002. [8] Both the furniture (markers) and all other aspects of the stage were white, as was the costumes (markers) of the actors. Using tracking technology and gesture-based control, the system projected images onto the stage setting and costumes – a milestone in using augmented reality in opera (Fig. 4). This production also broke down the fence between stage design and costume design. Through digital re-presentation created plentiful dramatic effects and different morphological visual images projected onto the stage and costume design.
- **Augmented Reality in Interactive Digital Archives**
Recently, digital archives have been used in interactive art and become a vital part of culture preservation. It creates new opportunities to teach, create interest in, and present historic artifacts. We have used augmented reality technology in our 2005 work *Immersive Chinese Painting-The Ten Gibbons*. [9] Pu Hsin-Yu (1896-1963) painted *The Ten Gibbons*, which today is owned by the Taiwan National History Museum. We used augmented reality technology and infrared cameras to allow the participant to move a banana with his hand to attract the gibbons to the original position in Pu's painting (Fig. 5). The sight of the gibbons hanging on the trees or standing in a valley presents a humorous visual "digital re-presentation".

Simulacrum World in Augmented Reality

Patrick Jordan's 2000 book *Design Pleasure Products*, argued that producing pleasure products is a central function of design. [10] Jordan's book is a response to the same motivations as augmented reality –

pleasure is the central goal. Canadian anthropologist Lionel Tiger presented four concepts of pleasure in his 1992 book *The Pursuit of Pleasure*. [11] Tiger's four concepts play an important role in designing augmented realities:

- **Physio-pleasure:** This pleasure comes from the sense of perception organ, including the sense of touch, taste and smell. *Contact Water* is a good example of physio-pleasure in augmented reality.
- **Socio-pleasure:** This pleasure comes from the interactive relationship between oneself and others. *AR Magic System* is a good example of socio-pleasure in augmented reality.
- **Psycho-pleasure:** This pleasure comes from emotional reactions. The design should be able to cause cognitive emotional reaction. *Tablescape Plus* and *ReactTable* are good examples of psycho-pleasure in augmented reality.
- **Ideo-pleasure:** This pleasure comes from people's values and their sense of knowledge. *Tablescape Plus*, *The Jew of Malta* and *Immersive Chinese Painting-The Ten Gibbons* are good examples of ideo-pleasure in augmented reality. The works teach and encourage participants to speculate and learn.

Augmented reality technology makes virtual world and real environments meet each other through digital information processing. It creates "digital re-presentations" and "simulacrum worlds," and also creates a new language and direction in digital art.

French sociologist Jean Baudrillard's *Simulacra and Simulation* argued that reality has been displaced by symbolic simulacra. [12] Baudrillard thought that the world simulated by media is more "real" than "reality," creating a "hyper-real" world, in which it is difficult to distinguish the real and unreal.

This paper discusses how in the digital era people become conscious of and interact with reality and simulacra, through the pleasures of art appreciation and immersion. By analyzing the media and form of augmented reality, we have new ways of discussing "simulacrum" and "re-presentation". Augmented reality uses information processing to deconstruct, transform, and re-combine, creating digital re-presentations and simulacra worlds where virtual images and reality coexist, enabling people to perceive hyper-reality. For example, *AR_Magic_System* processes people's faces to create "face re-presentation" and "identification re-presentation." It creates a hyper-real identity in a simulacrum world generated through augmented reality, and participants can become immersed in this simulacrum world by viewing and interacting with the art.

Conclusion

The origin of Jean Baudrillard's *Simulacra and Simulation* lies in the age of television, and it takes at times a cynical view of simulation in society. Baudrillard's concept of re-presentation mostly focuses on negative messages re-combined by the media and to create a simulacra world which transcends reality.

In contrast we take a more optimistic attitude. Augmented reality creates "simulacra world" in which we can take pleasure in immersing. Its re-presentation can stimulate participants (exemplary viewers) to think further about the purpose of the creators in using virtual information to project onto or replace real objects. By selecting and transforming virtual markers, augmented reality builds a complete different frame of mind and atmosphere. By interactively mixing simulacra and reality, participants can derive pleasure and enjoy the interactive feedback from the artwork.

In this paper, we simply point these concepts. We hope more discussions will be presented in the future.

BELOW THE BELT – PARTICIPANT EXPERIENCE IN A BREATH CONTROLLED INTERACTIVE ARTWORK

Giann Hughes

Contemporary theories of embodiment and affect are explored in relation to the breath-responsive interactive installation, *Below the Belt*. The artwork uses bio-sensed data to measure the breathing patterns of participants in an attempt to uncover the relationship between breath and emotion. The artwork forms the test-bed in an examination of how emotion and breath are considered in the construction of experience across bodily and social realms.

Fig. 2. *Below the Belt* participants, 2011, Giann Hughes, photo- graphic media, Copyright Pia van Gelder.

Introduction

Despite the development of body-responsive interactive art the vast majority of artists and researchers working within this genre have explored embodiment from an external perspective, privileging the senses of the outer body or the proprioceptive sense of the body in space. Few have examined perceptions of the inner body. Where the inner senses have been used to drive the work the participant's focus has often been directed towards self-reflection and their affecting relationship with the social sphere has been ignored. When the affective nature of social interactions is considered the works have commonly bestowed a pacifying and subdued meditative tone.

The interactive installation *Below the Belt* is a breath-responsive artwork exploring how the aesthetic experience of engagement with breathing and emotion can promote an awareness of embodiment. It amplifies the breathing patterns of participants to extend their expressive and perceptual awareness and their connections to the inner senses. Often we only become aware of these senses when we become unwell. This can lead us to alienate the body further in an attempt to dissociate ourselves from the discomfort, and so detachment becomes a habit. This work examines how breath awareness can subvert our customary tendency to favour the outer body above the inner body by magnifying our perception of our inner world. [1]

Below the Belt provokes the participant to explore the broader relationship between their breath, emotions and the social realm. It stretches their focus beyond their fleshy boundary to bring awareness to the subtleties of the affective relationship between these bodily responses and their social interactions. The primary motivation of this work is to take the lived experience of breathing out of the private realm and into the public. It attempts to understand participants' first hand accounts of their experience using a phenomenological approach as a way of focusing on the whole bodily being.

In this paper I briefly explore theories of embodiment and affect to assess the role that emotion and breath play in bodily and social domains. I continue by positioning this work in relation to other breath-focused interactive artworks before providing some context to the work itself. The paper concludes with reflections on the experiences of a selection of the participants who encountered the work and on how these findings are informing my ongoing research in this area.

Embodiment and Affect

Contemporary approaches to the study of embodiment and affect theory sustain inquiry into lived experience, subjective perspectives and meaning making. The existentialist phenomenological tradition questions the dualistic nature of Cartesian thought that bifurcates mind and body. In *Phenomenology of Perception*, Maurice Merleau-Ponty explained perception as bodily experience where the body is subject distinguishing between the objective, physiological entity of the body and the phenomenal body that we experience the world through. [2] However the term embodiment is still often misused to describe the body's role in cognition while still maintaining the Cartesian paradigm. I believe embodiment is the very nature of being and the primacy of the body in constructing experience.

Medical anthropologist Margot Lyon suggests that because the experience of embodiment is accentuated when we are emotionally present in the world, we can study embodiment by studying emotion or a bodily capacity linked to emotion, such as breath. [3] The respiratory function is related to feeling in part because of the nerve fibres it shares with the autonomic nervous system, which plays an important part

in emotion. For example, slow, deep breathing can regulate the functioning of the autonomic nervous system by increasing parasympathetic activity (rest and digest responses), effectively bringing the involuntary autonomous nervous system into the realm of the voluntary. This argument does not attempt to diminish emotion to the function or arousal of breath. It acknowledges that behaviour cannot be reduced to physiological processes and makes no attempt to match feelings with particular breathing patterns.

It should be noted that whilst embodiment and affect theory has only recently been articulated by Western scholars it has of course been studied through practice based research for many centuries by philosophers of Eastern traditions who have used breathing practices and meditative states to reflect on states of consciousness.

Body-responsive Interactive Art

Body-responsive interactive art is entirely reliant on the actions of the participant, which becomes the instrument of communication. The participant responds to the work through their embodied reactions, the work reinterprets this feedback and so the dialogue unfolds. Their aesthetic experience is defined not in terms of beauty but rather through their experience of this interaction. It is this experience that creates meaning for the work. Body-focused interactive artworks provide a unique platform to engage in dialogical exploratory practices.

As biofeedback technology has emerged, so have creative ways of engaging with digital breath-focused interactive artworks. *Below the Belt* is situated amongst works that are activated by breath such as George Khut's work *Cardiomorphologies v1*. [4] My research looks beyond the self-reflective aspects of this focus to the broader affect of breath on the social realm. Works being created in this area include Christa Sommerer and Laurent Mignonneau's *Mobile Feelings*. [5] Also Thecla Shiphorst's wearable body architecture *Whisper*, which uses breath to explore human interactions in the social domain. [6] Where as most artists working in this area have focused on the meditative aspects of reflections on their work I am interested in provoking a broader range of responses from participants to allow them to more fully explore the complex relationship between their breath and emotions. The artwork *Below the Belt* provides the 'black box' in which to examine these theories.

Below the Belt

Below The Belt is an interactive installation that affords participants the space to feel the affective nature of emotion, and its role in human experience, through the prism of breath. It attempts to re-embodied interaction within video installations, to amplify and extend the bodily experience of participants. The installation uses affective computing and the breath of participants as the vehicle to explore embodied subjectivity. It places embodiment theory and the affecting influence of emotion and breath centre stage, directing participant attention to their breath to explore how it is affected by the instruction. The participant is presented with a playful environment to experiment with breathing techniques and an opportunity to cultivate their breathing literacy. Participants interact with breathing coaching Tony, made visible through a single channel projection, who guides them to slow down their breath and increase the natural rise and fall of their abdomen.

The installation relies on wearable computing to make Tony's instruction audible – protective boxing headgear, implanted with wireless headphones, provide an immersive auditory environment blocking out extraneous sound and focusing the participant's vision on the projected video. A biosensor embedded in a champion title-boxing belt wirelessly relays the degree of stretching to an Arduino microprocessor attached to a laptop. The microprocessor feeds this stream of data to Max/MSP software (Cycling 74), which identifies patterns in the data attributable to the pace of breathing and degree of abdominal movement. The laptop, visible directly under the projected video image, displays the Max patch, the guts of the processing driving the work. This includes a simple graphic representation of the participant's pattern of breathing.

The first stage of the encounter involved attaching the belt, immediately drawing the participant's attention to their upper abdomen, the region under measurement. Tony then spends the first minute setting the scene and explaining the rules of engagement. During this time a baseline is calibrated for each participant according to her or his breath patterning. The participant's overall performance is judged according to deviations from this baseline. Thereafter, at regular intervals the average value for the preceding period is calculated and compared to the participant's previous results. These differential values are fed to Jitter software which triggers the appropriate video vignette of Tony's feedback. The work does not attempt to make judgments about the participant's natural breathing patterns as performance is measured in terms of changes in the pattern of breathing during the encounter.

The breath coach, Tony O'Loughlin, is actually a boxing coach from Elouera-Tony Mundine gym in Sydney. Tony's antagonistic coaching style starkly contrasts with instruction found in the more popular meditative breathing practices. He takes each participant through five rounds. After each round he provides feedback, often harsh, on their breathing performance for that round, based on the Max patch results, and offers appropriate breathing exercises to improve performance in the next round. At the end of the five rounds the competitor's overall performance is calculated and Tony proclaims their performance with all the fanfare of a championship bout. Tony's aggressive motivational style was chosen as a way of provoking a reaction that is at odds with the calm, smooth breathing he demands. The participant has the challenge of obeying instruction to relax and breathe deeply, delivered in a forceful and abrasive style. The natural body response to this harsh feedback for some may be an increase in their nervous system's sympathetic responses leading to shallower, faster breathing.

Through the metaphor of boxing the work examines the tensions between competitive contact sports and the inward focus of supportive breathing practices. It plays with the constant mediating role that breath plays in the bodily and the social realm. While the participant is sensing and performing their responses they are also differentiating and appreciating the systems interpretations, in the full knowledge that they are being measured. Although the work relies on rhetoric grounded in competition the reality is that each participant is only ever competing against herself or himself, never with each other. The irony is that when participants get caught up in this sense of competition the natural reaction of the body is to retreat to flight or fight mode which produces shallower, faster breath consequently impairing their performance.

Understanding Participant Experience

When John Dewey redefined aesthetic experience, he contended that the work that art does takes place within the entire process of art making. Art is more than the material 'work of art', it is the development

of an experience and recognises the aesthetic experience in everyday living. Pragmatist aesthetics elevated the experience of the audience as a vital component in completing an artwork. It proposes that to fully assess any work of art the experiences of those who interact with it must be considered and understood. [7] This philosophical position supports the dialogical aspect of my inquiry that seeks to understand the lived experiences of participants interacting with this work.

There is very little empirical research on audience experience of interactive art. [8] Whilst various literature has examined participants' creative engagement with body-focused interactive artworks these approaches have mainly used third person investigations which rarely examine the physical, emotional and affective experience. Where they have taken into account the quality of experience they have often employed methodologies that take an embodied cognitive approach, which maintains that the mind is split from the body. In addition purely first-person accounts of participant experience can easily be dismissed in academic realms as anecdotal, unless they have been rigorously interrogated. My exploration is motivated not just in attempting to understand the experience of interacting with the artwork but also in seeking to understand the participant's interoceptive exploration. This area has been neglected, perhaps due to the difficulty of articulating experiential response, yet it remains central to the way in which we interpret and understand an artwork. The phenomenological approach used in this investigation recognises the body as our basic mode of being in the world in terms of both the process and practice of this research.

The relational practice that grounds this work seeks to develop dialogue between the participants, their audience and the artist. Seeking to understand their experiences during their interaction with *Below the Belt* led me to enter into research-focused dialogues with seven randomly selected participants. Unstructured interviews, conducted immediately following the encounter, used open questions to initiate a conversation about the experience. Participants were asked to recollect their thoughts, feelings, perceptions and sensory memories of the interaction. More specific questions followed, focusing on observed body language, gesticulations and breathing quality.

Reflections

A selection of participant quotes are found below along with a brief description of the themes identified in these responses.

BREATHING LITERACY

The diverse quality of participants' connection to their breathing is illustrated by the following statements:

S1: "I never think of my breath, it's just kind of always there".

S3: "Tony's advice was at odds with the instructions I was given as a kid with asthma. I used to be told to breath into my chest and not into my belly. That new logic was really hard for me."

ENGAGEMENT

Participants chose to engage with the artwork in a variety of ways as described below:

S2: "I got swept up by the competition. I got heavyweight but I found myself quite anxious and tight in the process. Although I fooled the system I feel like I cheated myself".

S4: "About half way through I could see the graph on the laptop and figured it was my breathing. I hooked on to it for the rest of the time".

PARTICIPANT CO-EXPERIENCE

The social aspect of this seemingly solitary pursuit was perhaps impacted by the competitive tone of the work. Some took the opportunity to perform to their audience – on a number of occasions the participant, on stepping out of the installation, would announce to their 'audience' the title Tony had given them, often in the same flourishing style he had used.

S2: "I was determined to beat my girlfriend – she got super-heavy weight."

The challenge for both interviewer and participant in understanding these encounters is the limitation of words to describe an embodied experience. This required attentiveness to all the forms of communication used by participants in relaying their experiences. They were encouraged to verbalise their body language and take time to unearth meaning where there was ambiguity in their language. Overall, participants reported an appreciation of the opportunity to have their breath foregrounded in this way.

Some participants struggled to recollect aspects of their encounter. It is intended that future studies employ the video cued recall method to support participant memory. The audiovisual nature of this medium honours the temporal, embodied and emotive nature of the artwork and captures the participant's body language, gesticulations, breathing quality and tonal subtleties of voice.

GAMES: FROM BLOCKBUSTER ENTERTAINMENT TO IRREVERENT EXPERIMENTS AND LOVELY BASTARDS

LYNN HUGHES

This paper presents games as the post-cinematic cultural form. In the era of powerful accessible tools and internet enabled distribution, there are broad questions about what and why (high?) art is. What is clear is that the increasingly broad field of games already includes everything from blockbuster entertainment through serious games to 'games d'auteur' and experimental forms such as the five examples presented.

Propinquity: 2010–11, Lynn Hughes and Bart Simon with team, Custom wearable sensors and interactive visuals. Photo: Brian Li.

In the contemporary art world, even in the new media sector, games are often still caricatured as 'mere' entertainment - somehow essentially superficial. They are at best a minor mode or a trendy margin. But I am interested in games because I think they are absolutely central -formally, technologically, socially and artistically. Indeed, it is becoming increasingly clear that, in the way that cinema was the central cultural form of the 20th century, games are the central form of our time. [1] This is not to downplay the persistence or importance of other inherited or current forms of art, it simply describes the contemporary, cultural state of affairs.

I would characterize the centrality of games in two ways.

The first is formal: current post-cinematic culture is the culture of the computer rather than the camera and, by implication, of active rather than passive relationships between audience and cultural product.

Computer and network-enabled interactive media imply a designed relationship between a closed, authorial shape (typical of, for example, painting, photo or cinema) and a more open, participative space. The participative space is still a designed one but is open, to one degree or another, to user choices or paths and may have emergent qualities - whether deliberate or unanticipated. [2] While this is generally true of interactive media, digital games articulate this relationship in a particularly explicit and clear way so that we can see them as the definitive form of interactive (digital) media.

A, perhaps more compelling, description of games puts the emphasis on the notion of exploring a system. Playing a game leads us to discover an underlying, constructed / designed system with its affordances and assumptions. [3] In a nutshell, games stem from, and point to, the world as increasingly systematized and they ultimately suggest that we need to be both aware and critical of the implicit, constructed and systemic nature of our realities. Here again games can articulate in complex, critical and compelling aesthetic ways, key contemporary preoccupations and situations.

Beyond these formal arguments, it seems essential to point out that people who dismiss games, or rather don't see them, almost always have little or no playing experience. Perhaps even more importantly, they have little idea of what the field of games looks like, even at this relatively early point in its development, in terms of breadth, depth and variety. To a significant extent this is simply because of the pace of development. Games have really developed over about the last forty years and the acceleration of development after 2000 was matched only by the revolution in approach and audience in the last two or three years. Most art critics and curators are over forty and so it is not surprising that they don't understand games. To them, games are the violent blockbusters that all look about the same, along with, perhaps, the recent addition of lightweight family entertainment for newer controllers like the Wii, Move and Kinect. A few curators are becoming aware that there is an art fringe to the game community. But art games or game art are just a margin of what is already a very rich, varied, artistically and socially exciting arena. It is already clear that the field of games will soon look very much like cinema in that it will include everything from blockbuster pure entertainment (like Hollywood, much of it repetitive and uninventive but occasionally something both commercial and good) through games d'auteur, to low budget independent and experimental genres.

Even a book like *Gamescenes* [4] makes the mistake of seeing the games industry as relatively monolithic and, while this may partly be because it was published in 2006, it is also because it looks at games through an art / not art lens that is essentially rooted in the fine or visual arts. In his introduction, Matteo Bittanti suggests that games cannot be art because they have too big an audience (!) [5] Like much cinema d'auteur and experimental cinema, independent and experimental games also (usually) have smaller audiences.

At the same time, games' very centrality is firmly linked to a digital culture that is radically questioning who makes art and for whom. As David Robbins suggests in his collection of essays called *The Velvet Grind* [6] the rapid and radical democratization of access to sophisticated networks and digital tools has already enabled a culture of 'amateur,' users and assorted individuals and groups, who even a decade ago would not have had access to the means to both sophisticated production and distribution. [7] In the games industry this is leading to rapid development of the independent sector as alternatives paths - from individual, to micro and small, development studios- become viable. Arguably more viable than the ungainly mega studios.

As a corollary to the increasing accessibility of sophisticated, affordable tools for creation and distribution, many polarities supported by more traditional social and cultural models are beginning to break

down. These include creator versus consumer, of course, but also high vs popular culture. Robbins also suggests that the quality and relative accessibility of new technology and distribution networks means that independent and experimental work is no longer condemned to obscurity. In fact he contends that we need to end the “tired theatre” of opposition between artists who cultivate exclusivity and look down on mainstream culture, and a mainstream industry that cultivates the illusion of speaking for the masses and encourages a suspicion of intellect and experimentation. [8] I would argue that many other traditional distinctions such as art vs design, object vs performance and virtual vs physical are also, at the very least increasingly unstable. Contemporary game culture participates in and provokes this fertile instability.

The visual part of this presentation will look at a few recent games that experiment in different ways with the game form. (Needless to say, in such short presentation it is difficult to suggest the variety and breadth that is currently emerging around games or to decide what angle to privilege). The four games I will present are: *Propinquity* (2010-11) a full body game by myself and Bart Simon, *B.U.T.T.ON* (2010) by Douglas Wilson of Die Gute Fabrik, *A Slow Year* (2010) by Ian Bogost and *Chain World* by Jason Rohrer (2010).

THE TALL AND THE MOBILE: A MEDIA ARCHAEOLOGICAL INVESTIGATION OF THE MEDIATIZATION OF OUTDOOR SPACES

ERKKI HUHTAMO

This paper tries to understand the current modalities of outdoor media use by excavating the processes of their becoming and the various cultural forms that have anticipated them. The theoretical issue informing the paper is the formation of the "outdoor subject" - the observer, the listener, the interactor - of media culture.

Media scholars have traditionally focused on audiovisual forms that are experienced indoors and in static settings; cinema-going and television spectatorship provide good examples. Researchers are slowly beginning to realize that such an emphasis covers only a part of the complex terrain that constitutes media culture. That part may even be shrinking, thanks to current developments within urban environments and experiences. Not only are metropolitan cities covered by high-tech media attractions such as giant LED-display screens; a growing number of citizens are walking or cruising through such spaces with media devices in their hands. The current smart phone revolution may be just a beginning for much more dramatic technological, behavioral and cultural changes.

This paper will approach this situation from a media-archaeological perspective, trying to understand the current modalities of outdoor media use by excavating the processes of their becoming and the various cultural forms that have anticipated them. These earlier forms are not treated as clear genealogical steps leading to the present condition. Rather, they are analyzed as symptomatic manifestations of contradictory motives and discursive fragments that have at various times and contexts highlighted issues the current media culture may erroneously believe it is encountering for the first time. Such issues cover, for example, the saturation of the city space by commercial messages like billboards, and the attitudes toward them; the varied early forms of "mobile media" such as "walking human posters" (sandwichmen), and the practices of using fans, watches, and other forms of "proto-wearable" media; and the complex relationships that developed between them. Ultimately, the theoretical issue informing the paper is the formation of the "outdoor subject" - the observer, the listener, the interactor - of media culture. The process of its becoming is far from clear-cut, involving numerous detours, lacunas and pot holes of history, buried deep underneath the "officially" recognized and legitimized media cultural developments.

The evolution of outdoor advertising in the nineteenth century is an important topic to investigate, not only because of its proliferation and institutionalization, but also because of the enormous enlargement of the ads themselves. The earliest signboards and broadsides were relatively small. Their scale could be characterized as anthropomorphic, which more or less corresponded with the dimensions of the living environments. From the Middle Ages to the early modern times, the elements that did not conform to this principle had to do with power. Cathedrals, city walls, castles and town halls were meant to impress the 'common people' by their size. Gothic cathedrals had enormous rose windows made of thousands of pieces of stained glass. Standing under Bernini's immense cupola at the new St. Peter's in Rome was meant to convince the visitor of the might of the catholic church. Still, even extraordinary public sights, such as the astronomical clocks built into the walls of churches or townhalls (sometimes on the outside) often consisted of relatively small elements. Their clockwork-operated *Jaquemarts* performed at regular

intervals, but the mechanical moving figures weren't necessarily larger than the automata demonstrated at fairs by itinerant showmen.

An indication that the situation was likely to change was provided by an early nineteenth century French cartoon that shows two men trying to read announcements posted on the wall. [1] One of them is peeking at the densely filled sheets from a ladder, while the other is using a telescope. Although the point of the cartoon is the absurdity of posting long official notices on the wall, its 'statement' can be generalized. Broadsides began not only piling up, but also climbing up along the wall, which made reading their messages difficult. Interestingly, broadsides were sometimes called 'handbills,' which refers to their other use: the practice of distributing them from hand to hand.

During the nineteenth century the situation changed dramatically, partly due to economic developments and changes in the urban environment, partly because of improvements in printing techniques. Toward the end of the century it had become possible to produce very large chromolithographic posters in multiple colors. Graphic designers learned to deal with large size, concentrating on elements that could raise interest, and be detected from a distance. They simplified the textual part of the message, focusing on the trademark and what came to be known as branding. Advertisers also began to take into consideration the placement of the billboard within the 'adscape,' playing with issues of scale and perspective. An 'aesthetics of the gigantic' was in the making.

The development led to the opposite direction as well: from enlargement to shrinking. Lithography and its improvement, chromolithography, as well as the techniques of photographic reproduction, provided possibilities for an unprecedented production of "smaller than usual" pictures. Illustrated magazines were part of the trend. Tiny mass-reproduced images spread to any imaginable place, even though the fashion among society ladies to dress up in photographs (a strange echo of the 'animated sandwiches' walking on the streets) proved to be short-lived. [2] Pictures filled up photographic albums and scrapbooks, and were also used as raw material for parlor pastimes, such as the creation of colorful collages of 'found' imagery on the common folding 'screens' (room dividers). So the enlargement of public images was accompanied by its reverse: miniaturization and privatization.

The mediatization of public space was reflected in the cultural imaginary. The dream worlds of emergent consumerism were internalized as shared (day)dreams. These were expressed in complex ways by cartoonists. A well known motive was the "bill poster's dream" that showed a bill poster sleeping next to a wooden fence completely covered by overlapping broadsides; their combinations led to the formation of surrealist-sounding sentences (anticipating the *Exquisite Corpse*). This idea was anticipated already in the 1830s in a series of prints titled "Cross Readings" (W. Jeffery, London), but without the dreamer (the composite messages were read column by column from top to bottom, in the manner of a newspaper page). The dreamer of consumerist dreams turned into a cultural topos that appeared in numerous versions, including political and propagandistic ones. In the time of the American Civil War, the Confederate President, Jefferson Davis, was put into the dreaming bill poster's place as the "rebel bill-poster" by *Harper's Weekly* (March 1862), seeing the war as nightmarish "writings on the wall."

The outstanding summary of this topos tradition was Busby Berkeley's "optical illusion" sequence for the Warner Bros musical *Dames* (dir. Ray Enright, 1934). Young lovers, who are traveling in a tram, fall asleep in their daydreams. At the moment of losing consciousness, the seductive posters on the walls of the tram are associated by the male's (Dick Powell) mind with his girlfriend's face. This provides the entry point to an outlandish dream sequence, where scores of girls carrying advertising boards (with the girl's iconic face, doubling as the character and the star actor, Ruby Keeler) are transformed into a series

of elaborate fantasies following one another. The spectators are transported deeper and deeper into the logic of the capitalist dream worlds. The external is merged with the internal. The concrete manifestations of commercial media culture are situated in the lead mail character's, and as a consequence, into the spectator's head. The musical film (ironically and significantly, produced in the heart of the Great Depression) provides the device that weaves the outside and the inside together.

To understand the peculiar ways in which the large and the small, the external and the internal were merged together, one might use the idea of the "gulliverisation" of the visual environment, as I suggested twenty years ago. [3] The concept refers to a two-directional optical-cultural 'mechanism' that worked against the idea of a common anthropomorphic scale. The size of the human observer kept on shifting between gigantic (in relation to the *carte-de-visite* photographs or tradecards) and lilliputhian (in front of large billboards or below advertising spectacles in the sky). Something similar happened in the field of media: 'immersion' into an enormous circular panorama or diorama painting (and later, the cinema screen) found its counterpart in the act of peeking at three-dimensional photographs with the ubiquitous hand-held stereoscope.

Gulliverisation operated at the divide between the public and the private. The dimensions of the urban environment, with the skyscraper as its ultimate manifestation, became more and more 'inhuman' – as the cultural reformists readily pointed out – whereas the home provided a welcome return to the anthropomorphic scale. The countless miniature objects and images that dotted the Victorian parlor were a way of handing the inhabitant an illusion of control that s/he was more and more clearly losing in public outdoor spaces. The gulliverisation also raised the issue of the relationship between things that are near (tangible) and distant (unreachable). Mediating between these opposites became a part of the advertisers' strategies, even if it may not have been always explicitly formulated. The billboards gave products a monumental and 'universal' quality, associating them with the urban environment. Tradecards, newspaper ads and other tangible forms brought them close, making them tangible and 'personal.' At the fingertips such paraphernalia functioned as temporary placebos for the products the subject did not (yet) possess. Everything was mediated by 'magic' transformations – in particular, by changes of scale that were inseparable from the perceptions and motions of the observer (the potential buyer).

Similar 'bipolar optics' manifested themselves somewhat later in phenomena like the movie stardom and the ideological manipulation of the masses in totalitarian societies like the Nazi Germany. From around 1920 pictures of film stars became one of the most popular topics for *figurines*, collectable trade cards. The uncannily large faces that stared at the observer from promotional billboards and the cinema screens were shrunk to the size of one's fingertips: the object of adoration from afar suddenly was close and tangible. These pictures had an assignment in the expectations, promises and lust-evoking machinery with which the star cult was maintained. But they could be, if kept just like family pictures in the wallet, more than just a picture: the representation of someone who wasn't there, almost a part of that someone, a way of touching the thing that avoided being touched. The religious qualities that are often associated with the star cult may be the most apparent in the star figurines. In fact, they resemble mass-produced devotional cards, whose iconography derives from altar paintings and other large-scale religious representations. Advertising, the star system and the religious worship share the interplay between the monumental and the intimate. In this sense commercial billboards could perhaps be characterized as altar pictures for the cult of capitalism.

The Nazis were aware about the ideological possibilities inherent in the gulliverisation of the visual sphere. They harnessed new media, such as cinema, radio, and even television (still at an experimental

stage) for their purposes. They organized carefully 'orchestrated' mass events and symbolic acts, including 'spontaneous' book burnings, and the dramatically staged *inferno* of the Reichstag (for which they accused the Jews). Leni Riefenstahl's state-sponsored 'documentaries' *Triumph of the Will* (1934) and *Olympia I-II* (1938) were part of the media façade the nazis built to impress both the Germans and the foreigners. Massive billboard-like images of Hitler's face were displayed in the nazi rallies (reminding one of the strategies used by other totalitarian regimes), but the nazis also understood the power of the ephemeral. The ideological indoctrination of a nation depended not just on explicit propaganda and mass rituals relayed by the media, but also on seemingly insignificant channels. A company named *Cigaretten-Bilderdienst* was established by Joseph Goebbels' Propaganda Ministry to produce series of collectable cards placed in cigarette packs. [4] Their subjects included the life of Hitler, nazi uniforms, the *Anschluss* of Austria and the *Wehrmacht*. Predictably, there was also a series about the Berlin Olympic Games of 1936, which provided the lilliputhian counterpoint of Riefenstahl's colossal film. Handsome collectors' albums, with carefully scripted captions, were also produced; the nazi ideology was internalized as a 'side-product' of 'innocent' hobbyism.

Adding the fascination of the media apparatus to the collecting experience, the Munich-based Raumbild-Verlag published sets of 3-D picture-pairs of Germany's war efforts. [5] These were viewed with a stereoscope that was stored, together with the stereocards, within the album. The first volume depicted the Polish campaign of 1939. This evokes an important issue that cannot be elaborated on here: the proliferation of portable gadgets. [6] It may not have been very evident at first. In the late nineteenth century the amateur photographic camera was one of the few options. Portable radios, sometimes in the guise of everyday objects, like purses or even pinkie rings, were introduced already in the 1920s, decades before the breakthrough of the transistor radio. Eventually, mass-marketed gadgets like Sony's Walkman, Apple's iPod and the nearly endless variety of pocket-size mobile communication devices would change the users' relationships to their surroundings, including the public screens. In a few experimental cases (mostly in the media arts) the personal portable devices have been turned into terminals for manipulating the content of public screens. Understandably, this has been limited by the authorities, who want the ultimate control over the public space. Handheld mobile screen-based devices may be a challenge to the giant screens, but this challenge is perceptual, rather than interactive. It has to do with the quality of looking, its direction, mobility and intensity. These issues began with the gulliverisation of the visual culture in the nineteenth century.

PERIPATETIC VISUALIZATIONS: WANDERING BETWEEN ART AND SCIENCE

Christina Nguyen Hung

Through this work, I create situations in which viewers are required to negotiate space and engage in kinetic activity – to move their bodies in order to experience the “scientific” visual material on display. In this situation, no single perspective is privileged as ideal. It is designed to prevent a disembodied, cinematic mode of viewing and all the privilege, knowledge and power that such a mode of viewing implies.

*Neurons In Vitro, 2010, Christina Nguyen Hung, high-resolution image of chick embryo neurons in vitro
144 × 144 in.; 365.76 × 365.76 cm.*

In my most recent work with high-resolution images, I use microscopy equipment and techniques to visualize a wide variety of biological and geological materials. This work began with the assistance of a former graduate student of Clemson’s Bioengineering program. With his assistance I attempted to control the growth pattern of chick embryo neurons in vitro. While our efforts to produce a specific pattern (of text) were not successful, the failure of our experiment yielded results that were in fact more interesting to us than what we had set out to create. The neurons formed groups roughly equal in size and the groups were spaced evenly across the petri dish. The student confessed that he had never seen anything like it and I found the results to be visually, quite compelling. Unfortunately, due to disciplinary and research constraints, the student did not have the freedom to investigate our results further. For the student scientist, the work ended there. I on the other hand, photographed the sample – the entire 35mm petri dish -- at 10x magnification, a process that yielded over two thousand images.

Since I photographed the neuron culture at the end of 2009, I've been analyzing and aligning the individual images in an effort to create a single image that, when completed, will allow us to see both the individual cells and the entire in vitro environment, simultaneously. This produces a second interesting research problem: the visual (image) I am attempting to create far exceeds the capacity of any large format printing system and pushes the limits of new high-resolution digital display system. When complete, the printed neuron image will measure at least twelve by twelve feet.

Through this work, I intend to create situations in which viewers are required to negotiate space and engage in kinetic activity – to move their bodies in order to experience the “scientific” visual material on display. In such a situation, no single perspective is privileged as ideal. One cannot claim with any certainty that one has fully experienced the image and therefore cannot claim full knowledge of the object represented, without also having to acknowledge that their relationship to the visual material is contingent, deeply subjective, limited by their location in time and space and the physical limitations of one's own body. This situation is profoundly different from the way we are permitted to access large amounts of visual scientific data through software interfaces such as Google Earth, Gigapan and other screen-based interactive game/display spaces. Through such software interfaces, the viewer participates in a disembodied, cinematic mode of viewing and all the privilege that such a view implies, in terms of knowledge and power, remains unquestioned.

In the future, the large quantities of video and photographic material I gather will provide the foundation for interactive, semi-immersive art installations. Through these installations, I will be able to extend the conceptual basis for my current work by modeling extreme differences of vision. For instance, such work might permit us to imagine the world as it might be seen through a compound eye structure, much like that of the common housefly. The premise for this work being that it is entirely conceivable that such a visual experience might further reveal how our understanding of the material world and our relations to it have been entirely governed by the very anatomy, the limitations of our human, binocular visual system. It is my hope that these installations (images and immersive experiences) will allow us to rethink our relation to the world around us in radically new ways.

For example, in “Mapping the Empire v.1,” four HD video cameras are strapped to my wrists and ankles as I traverse a rock formation. A “map” of the terrain emerges from the process that suggests a mode of perception that is distributed, and polyvalent. This approach represents an inversion of the landscape tradition, which reproduces the perspective of a single human and uses the window as an organizing compositional metaphor. Taking my cues from GPS, and social networking technologies I employ an approach to visualization that is ecological, collective, and distributed: data is gathered, processed and then [de/re]composed. In Empire, the “map” I create nonsensical, more accurate as a record of motion defined by the logic of living flesh, rather than a systematic grid-like construction of space and time.

This claim: that a new, technology aided system of vision might allow us to experience the world in new ways by generating models of extreme difference, is not a new one. Many of us who work with new visualization technology hope that our work will inspire others, especially those within the scientific community, to be more open to “difference” or at least, to pause and consider other possible interpretations and meanings presented by the visualizations we all create. What is interesting to me about this claim is that few researchers seem willing to contemplate and articulate the assumptions about difference per se that are implied in such a claim, and even fewer are willing to explore the impact that their work might have on our cultural understandings of difference. What is implied in the claim is that we, as makers of new visualizations hope our work will inspire tolerance of difference and that representations

of extreme difference will affect our cultures, leading them to embrace diversity in material, thought, cultural and bodily forms. Obviously, I myself harbor this hope.

In part, what I hope to achieve through this work is, in a limited sense, an intervention of sorts. By using new visualizations technologies and processes, I create images and experiences that are not only different but that prompt questions about the practice of visualization in contemporary science and knowledge generated by these practices. In works like "Shattered," "Crushed" and "Burned," there is no attempt to ascribe a scientific value to the image. Historical, literary and cultural narratives are impossible to avoid when one looks at these images as they are constructed so that historical and cultural contexts are foregrounded, along with obvious references to imaging in science and technology. Through these images, researchers in science and technology are asked to respond to the social context in which they work in a new way, just as scholars in the arts and humanities must respond to new models of thought and creativity posed by developments in new technology.

WITH DESIGN IN MIND? 'MORAL ECONOMY' AND CONTEMPORARY DIGITAL CULTURE

Gordon Hush

Technological innovation is often characterised as producing a moral economy of “tempted” bodies, corrupted desires or utopian potential distorted by unlimited possibility, and juxtaposed to a now-foregone simpler era and existence. This paper seeks to explore the relation between subjective experience (consciousness) and the contemporary environment, in particular, the dissemination of digital technology within mobile devices.

This paper addresses the anxieties around ‘freedom’ in relation to emerging technologies and their use in contemporary capitalist culture. It does so by investigating the figure of ‘the consumer’ and its mediation of the relationship between the human, the artefactual, and the proliferation of digital devices and services. The failure of the discourse of consumerism to explain today’s culture reveals an *aporia* regarding the description of the mutually constitutive relationship between people and things. The historic attempt to ground theories of the human in rationality, desire and now the brain/genes reveals a fear of freedom, of the loss of demarcated boundaries, of definitive distinctions between moral and immoral categorisations of activities and pursuits. The technological capacity of contemporary capitalist culture, its devices, distractions, pleasures and potential represent a problem for the social sciences and their conceptualisation and explanation of the behaviour of human beings, as citizens, as consumers, as gendered identities, as workers etc, precisely because the non-human world is changing so dramatically.

Broadly speaking, social sciences assigned people identities, roles or types, which might vary or overlap with context but which were largely stable and enduring – even if less stable or enduring than those putatively assigned to earlier social formations or other cultures. This implied shared moral framework translated into ethical action, understood as personal conduct shaped to a greater or lesser extent by law and custom, as the citizen-consumer exercised choice as an indicator of personal (psychological) preference based upon calculations of utility framed within a set of circumstances including individual idiosyncrasy, socio-economic position and educational background. This position evolved over two centuries against a backdrop of the production of capitalist commodities, desirable objects and mechanical machinery – alienable and demarcated in time and space. The historically recent plethora of digital devices and immaterial services has complicated the relationship between people and things, consumers and commodities, to such an extent that previously held shibboleths describing consumption require revision. Arguably, the digital domain has altered the spatial and temporal rhythm of contemporary life to the point where neither ‘consumption’ nor ‘production’ remain unchanged and the modality of the inter-relation between the human and the non-human must be reconsidered.

The relation between human and non-human coalesces around technology. The anxiety over this liminal threshold has prompted an inquiry into whether some property of human physiology, perhaps the brain or the genes, can offer a foundation for this discussion; or whether a useful contemporary understanding of ‘human’ requires the radical re-thinking of our relationship to the non-human. Against the nostalgic evocation of an ‘authenticity’ accorded to certain desires or actions in which the human can be rooted this paper asserts the latter. Rather than devise a moral economy of action, exemplified in consumer activity, to define the limits of the human through notions of taboo, sin or the profane – without

denying the legal framework that codifies such concepts – this paper considers the concept of human as part of an evolving discourse emerging from contemporary culture and its formulation of a relationship of ‘co-shaping’ between people and things.

The historical evolution of the figure of the consumer and its centrality to contemporary accounts of life in capitalist culture is predicated upon the role of choice; where selection signals preference based around a calculation of value amongst equivalents or alternatives. This unification of bourgeois psychology with utilitarian economics sees a socialised homo oeconomicus as a self-directed individual acting in concert with personal desires and social norms. Consequently, the discriminating choices and purchases evidenced by goods and services assert an apparent unity of psychology and social life. This is the normal and normative individual engaged in the ‘biographical fiction of the self’ [1] through an interaction with the material culture of contemporary capitalism.

This fiction of the consumer is at odds with the historical evidence – most obviously when the pathological acquisition of objects, services or experiences are considered. The ubiquity of eccentrics, collectors, hobbyists, the predominance of habits, acquired, inherited or imitated behaviours, the over-indulgent or self-denying obsessive all serve to dispel such a myth. Indeed, the only possible existence for such an ideal-type consumer or citizen would as an absence, as a putative precondition that was ceaselessly interrupted and deviated from.

The nineteenth century’s expression of the utilitarian psychology through rational action as the precondition of identity production appears superannuated:

The classical bourgeois world view can be understood as a process of individuation, as the pursuit of pleasure. The pursuit of pleasure is the pursuit of the self; and the self, like the cosmos, is a system of relations tending towards a unique equilibrium. This has long since ceased to be a plausible view of either psyche or cosmos. [2]

As a result, homo oeconomicus, the homunculus of the ‘consumer,’ was rendered redundant just as the figure of the consumer was adopted by discourses as varied as law, political theory, marketing and sociology as the basis of an explanation of the particularly modern incarnation of ‘consumption. Here freedom to consume is the freedom to construct an idealised version of the self, to express through external actions the inner being. Consequently, the types of choices made, the preferences expressed are freighted with meaning and significance implying, as they do, the inner world of psychology, morality and personality. In this way the problem of choice, of particular choices or even the renunciation of consumerism are deemed to be moral considerations, ethical activities and problematically gendered experiences. Against, ‘economic man’ and his will expressed through the manipulation of the material world in accordance with a rationally organised desire for utility stands a hysterical figure that is prey to the irrational emotions and temptations of desirable commodities.

While social science added psychological and socio-spatial meat to the bones of *homo oeconomicus*, the ‘consumer’ remained the moral intersection of bourgeois psychology and utilitarian thought. The subject was considered an active agent who organised the world of inert matter or manipulated pixels on a screen, in the service of a desiring self. Critical sociology sees in this the realisation of an authentic selfhood stymied by the denigration of experience inherent in the ‘culture industry’ and an ‘ersatz individuality’ [3] as the result of a corrupted libidinal economy. The manipulation of commodities to manufac-

ture personal identity can involve a degree of 'risk' for the subject, as unstable identity formations, contingent upon consumption habits and practices, solidify into lifestyles, which are viewed as being to whatever degree deviant, immoral, or illegitimate.

This desiring consumer can be seen as the lodestone of a nascent 'consumerism' and 'consumer society,' a harbinger of modernity and the 'mass' consumer society of today. In doing so, alternative forms of exchange – non-modern, non-market forms, such as gift-giving – became the focus of a nostalgic privileging of the archaic that functioned as a fantasy of the 'real' or 'authentic' in human consumption that is apparently warped by the over-provision of commodity capitalism. Here the promised satisfactions of the commodity outweigh utility, and possession comes to be predicated upon meaning, or social worth, rather than functionality.

As a brief example it is instructive to consider the recent riots in the United Kingdom's larger cities. In an economic era commonly termed 'post-scarcity' – in which mass consumption prevails for the majority of the populace – even allowing for these recessionary times, much of the mass media coverage of rioting focused specifically upon *looting*, and the illegal removal of goods from retail environments (or other looters). People who were otherwise, and previously, considered to be consumers were denounced as *feral*, *criminal*, or *manic* and their actions immoral, sinful or unreasonable. Such unruly consumption does not bear upon the *use* to which any goods appropriated would be put, but simply describes the manner of their acquisition. It is interesting to consider that the goods liberated from stores – at least as reported in the popular media – were consumer items (widescreen TVs, mobile phones, designer clothing: portable, high-value items), which simply replicated the types of goods already possessed by many of those rioting or looting. Indeed, the difference between looting and shopping appeared to be the unregulated manner in which it occurred – the absence of law, social convention, surveillance and the disciplinary apparatuses normally associated with these. So, the rationale governing the actions of individuals was not simply a desire for utility, economic necessity or, in most cases, pre-planned criminality. It is precisely in the *irrational* aspect of these events, in their *group* character that we see the failure of conventional models of the consumer.

By characterising the riots and looting as *immoral* and unreasonable acts the political and media apparatuses seek to re-assert the fiction of the morally responsible, rational and law-abiding citizen-consumer at the heart of contemporary capitalist society. Even when criminality intrudes and individuals are suborned in some manner this must be construed as a *deviation* from the norm that creates transgression. Beyond assertions of "mob rule" there was no attempt to understand the behaviour of the participants in these events as members of a group in which the group is the unitary entity, and that its behaviour and rules of operation and engagement would not conform to those normatively expected of individual consumers. The concept of mob rule was deployed to explain why an aggregation of individuals behaved in such unexpected fashion.

However, a contradiction emerges between the rational and irrational, moral and immoral since the apparent co-ordination of mob or looter activity, was deemed to be rational, planned and criminal. And the tools that allowed this to occur? Digital devices. RiM's Blackberry 'phones and its messaging service were pinpointed, one politician to urging a 'BBM curfew' in London. However, the hysteria highlighted here by those unaware and fearful of the technological possibilities of digital devices (and the many alternatives to BBM) exposes a fear of emerging technology that echoes the alarm over commodity fetishism by critical sociology – that otherwise rational, discerning, morally upright individuals will be seduced into inappropriate activities by *objects*, either alluring commodities or technologies that confer a seditious set of freedoms upon their users.

Into the 'black box' of the technological device disappears the rule of law and the citizen-consumer; by simply assenting to the potential of such technologies, so this logic goes, we are losing, undermining or deforming our humanity – a physiological as well as moral corruption occurs because our bodies and our minds are embroiled. The possibility of the corruption the flesh and the mind of the users of such technology through the stimulation of illicit or novel desires re-animates religious conceptions of sin and taboo in the contemporary world, even underpinning notionally secular discussions. The degree of freedom putatively offered by digital technology, whether in the web itself, the communications and interactions it makes possible or the purchase of goods and services it facilitates, seems to escape regulatory purview – where are the digital police, and what might they term a crime? In the absence of the citizen-consumer and a pseudo-rational pursuit of utility, how are we to determine the nature and conception of the human agent and identify appropriate limits upon action? How is it possible to determine the *authentic* human desire or action from its inauthentic counterpart, which arises merely from tempted flesh and seduced mind, born of an excess of possibility?

One position can be phrased as: if we distinguish truth from falsity, the authentic from inauthentic, based upon a combination of physiology and psychology then we can legislate accordingly. The enduring appeal of medical discourses in the arena of consumption is evidence of this: including 'hysterical' women being pathologised as kleptomaniacs or phrenology revealing thieves. Descartes' mind/body dualism here hints at resolution, if only we know where to look. This putative re-unification of the biological and the symbolic, of matter with meaning, whether removing the false freedoms of technology or the fetishistic deception of the commodity-form, would allow for authentic experience of the world, discrimination between the true and the false, the consecrated and taboo in a contemporary and technologically permeated world. A 'moral economy' of action might emerge that would reconcile the human with the non-human by asserting what it was permissible to ask of the world and those within it. No longer would desire (cause) result in an immoral or inauthentic longing or wish (effect).

This is precisely the promise of explanations premised upon the relationship between the social and the natural or medical sciences. For instance, the emerging area of neuro-anthropology seems to promise just such a reconciliation via its address to the 'encultured brain' and investigation of the relation between physiology and culture. Equally, developmental psychology or behavioural economics seek to patrol and map such terrain in their own distinct fashions. A more intriguing starting point for considering the relationship between technological culture and human behaviour might be Marshal McLuhan's famous dictum that media, artefactual as well as communicational, are 'extensions' of humanity. Such formulations foreground the relationship between humans and non-humans, highlight experience and invite a discussion of consciousness under specific conditions, rather than as a human attribute absent in non-humans. In proposing a relational understanding of consciousness, rather than its 'medicalisation,' we avoid a reduction to the brain as site and origin of consciousness (intention).

Explaining human action in this manner requires unpicking the enigma of the mind/brain (consciousness) by resorting to technologies capable of imaging or 'imagining' the brain's operation. In imaging the brain in search of consciousness and the source of human action, science must attribute to it changes of state that are visible and recognisable, to which are assigned functions, states and operations: to these, in turn, is attributed a relationship to consciousness and action. In relation to Persistent Vegetative State (PVS), we expect or require patients to respond to stimuli – questions, medical probes etc – in the manner of the healthy. Failure to respond as expected and they are deemed to be functioning imperfectly or not at all. However, they may simply be functioning – interacting with their environment and us – in a markedly different or altered fashion, which we are failing to recognise, comprehend and respond to in our turn.

The various medical technologies for inspecting and interrogating the brain as it operates include Positron Emission Tomography (PET) and functional Magnetic Resonance Imaging (fMRI), both offer indications of levels of cortical activity in patients, but establishing how these quantitative measures relate to qualitative experiences or states of mind, or even capacity for such things, is problematic. The multi-coloured images produced are intended to correspond to levels of varying neural activity. However, the description of such fluctuating processes in no way supplies an explanation of their role in or relation to conscious experience or intentional action. Emerging digital technologies appear to complicate the question of what it is to be human, and identify a specific anxiety on this point with regard to contemporary culture. The reconciliation of biology with the symbolic, physiology and culture, in a comprehensible relation of cause-and-effect is both promised by technologies, such as PET or fMRI, and undermined through the generation of innovations in how humans and non-humans interact, the expansion of possibilities for experience and affective transformation.

It may be instructive to pursue the relationship between humans and non-humans, the association or networking of actants (Latour) or the relation between organisms and their environments discussed by ecological psychology, which 'affords' experiential possibilities for individuals and populations. This allows a 'postphenomenological' (Verbeek) [4] analysis of the relationship between people and things in which the Cartesian privileging of the human subject is circumvented through an analysis of the 'ontological relationship' of affordance forged between 'organism and environment.' [5] Specifically, this asserts the mutually constitutive relationship between people and things:

... the concept of mediation helps to show that technologies actively shape the character of human-world relations. Human contact with reality is always mediated, and technologies offer one possible form of mediation. [However...] any particular mediation can arise only within specific contexts of use and interpretation. Technologies do not control processes of mediation all by themselves, for the forms of mediation are always context-dependent [...]. [6]

The immersive engagement with technology obliges the human body to become the repository for the forms of experience that arise: the aesthetic and sensorial experience generated in the relation of affordance acts to transform cognitive capacity, as anyone who has ever looked through a microscope or a telescope can testify. Latour's re-discovery of Tarde's rejection of a 'primordial identity' in favour of a constant process of differentiation of 'being' through 'avidity,' or having, implies that every actant is an 'unstable aggregate' defined by the qualities it possesses.

Subjectivity, corporeality is no more a property of humans, of individuals, of intentional subjects, than being an outside reality is a property of nature [...]. Subjectivity seems also to be a circulating capacity, something that is partially gained or lost by hooking up to certain bodies of practice. [7]

Consequently, the continuous transformation of subjectivity through the experience of difference is exacerbated by participation in the technological arena. The relationship between people and things functions as a medium within which being is articulated to having as an 'affordance' that re-defines subjective experience: this transmission of experience allows the 'differentiation' of the individual from itself in space and time. So, possession is not purchase, acquisition or ownership but the re-formulation of the relationship between 'being' and 'having' in which concepts of morality are dispersed by technology. In place of desiring consumers, 'unstable aggregates' constituted by their historical experiences and technological relations of affordance coalesce. The plenitude offered by digital devices and the service-based interactions they support 'affords' a range of experiences appear 'immoral' and corrupted only when

viewed through the lens of the nineteenth century and its economy of desire subordinated to rationality.

LEAF++

Salvatore Iaconesi & Luca Simeone

Leaf++ is the product of a research project that aims at designing a prototypal interactive system involving computer vision, gestural interfaces, augmented reality technologies and cross medial platforms to create a novel tool to experience botanical information about plants and their leaves.

A computer vision system in a mobile application is able to recognize the leaf and to show available information.

Leaf++ logical architecture (courtesy of the authors)

Introduction

“The Third Landscape – an undecided fragment of the Planetary Garden – indicates the sum of the spaces in which man gave up to nature in the evolution of the landscape. It regards urban and rural forgotten places, spaces for transit, industrial wastelands, swamps, moors, bogs, but also the sides of roads, rivers and train tracks. The whole of these forgotten places are reserves. De facto reserves are: unaccessible places, mountain tops, uncultivated places, deserts; Institutional reserves are: national parks, regional parks, «natural reserves».” [1]

Gilles Clément's Planetary Garden is one of the most suggestive answers to the mutation of the definition of urban space. Planetary Garden is to economic and urban globalization what urban gardens were to the cities of the 19th Century.

The Third Landscape is a connective fabric composed of residual spaces that tend to take a liquid state, never preserving shape, resisting governance. Classical preservation or environmental conservation

tools such as surveillance, protection and the creation of limits and borders cannot apply to the Third Landscape without destroying its characteristics, as Clément writes [2] “not property, but space for the future”. An idea of space that goes beyond the ideas of landscape as a place for identity, being used as an asset for local societies, and as a strategic tool for memory.

As John Barrell spoke about “the dark side of the landscape” [3] while pointing out the imposition of a point of view of a single social class, with Clément we could speak about a “light side”, for the Third Landscape is not an exclusive model but an inclusive one: “a shared fragment of a collective consciousness”. It is based on a planetary remix (brassage) which is at the origin of the current richness of ecosystems. [4] Clément talks about the necessity of training our gaze into recognizing and understanding the Third Landscape. This requires a new possibility for vision and knowledge dissemination in urban natural environments, a renewed sense of aesthetics, and a morphed sensibility for the possibilities for interaction and communication offered by our surroundings.

Our current interaction and interrelation with the natural environment in urban spaces is mainly delegated to an institutional definition of borders and is rather far from the traditional knowledge of the ecosystem and its elements. Globalization and daily routines often force human beings to recognize plants and vegetables only in terms of their use in products that are found in supermarkets, or of the trees and bushes that decorate the sides of our roads. People progressively lose contact with the knowledge about the seasonality and origins of vegetables as they have come to expect any given product at any given time in a supermarket. One study, [5] among many other studies of a similar scope, gave advice to farmers in remote parts of the world encouraging the production of off-season products for export and highlighted this practice as a truly effective marketing strategy based on the documented assumption that consumers want specific products all-year-round.

Stepping outside of the supermarkets, we see that plants still remain within the great unknown as regards the majority of inhabitants of urban spaces. In cities, plants populate the periphery of our world view, living a life that is mostly aesthetic and excluding practically all forms of knowledge about their origins, characteristics, benefits and roles in the ecosystem, which remain largely hidden from the majority of citizens.

Leaf++

Leaf++ is an ubiquitous, interstitial information tool.

It is designed as a new “eye” that can be used to look at the natural landscape of our cities.

It is designed to help us see and understand the Third Landscape.

Leaf++ is an augmented reality system which employs computer vision techniques to recognize plants from their leaves, and allows us to associate them with digital information, interactive experiences, and generative aesthetics whose purpose is to create a disseminated, ubiquitous, accessible form of interaction with the natural environment, realizing a suggestive, exciting, desirable and accessible contact with the knowledge, wisdom and awareness about the inhabitants of the natural ecosystem in our surroundings.

Leaf++ shifts our focus in the vision of urban landscapes.

It is a tool for a new vision which, through augmented reality, enables the creation of an additional layer on our visual landscape: an infoscape and information landscape which is directly and coherently added to our vision; a new field of vision that is accessible by looking at the world through a mobile device which acts as a new lens on reality; a new vision in which leaves and plants come to a new visual life as the computer vision system actively searches for them and highlights them, populating our view with information about their origins, living conditions, characteristics and interactions with our urban/natural ecosystems.

Leaf++ acts as a distributed, dynamic, real-time, emergent geographer of the Third Landscape: each vision of a member of the plant kingdom in an urban space triggers a mutation of the map which is shared in realtime by all persons using Leaf++, providing a fluid cartography of the Third Landscape. These new visions are turned into an ubiquitous sensorial experience, transformed into morphing, moving images and sounds which create a state of wonder that further connects us to this new visual landscape.

Methodology

The Leaf++ project has been designed and implemented through the following methodological steps:

- initial briefing, which produced the definition of the concept;
- the choice and experimentation of several technologies which could be used to realize the concept;
- the design and implementation of several prototypes, which were used in an iterative, participatory process;
- the generalization of the best prototypal solutions into an open platform;
- the usage of the resulting platform to create two use cases, for education and artistic performance.

Leaf++ was intended as an augmentation for vision, to increase the level of awareness about the natural environment, to promote the establishment of a collaborative set of practices for dissemination, sharing and communication of knowledge and information about the ecosystem, and to create an ubiquitous digital interactive layer onto the natural environment that could be used for education, expression and for artistic and performative purposes. Anthropology, Cognitive sciences, Biosemiotics, Environmental Psychology and Aesthetics, together with a wide range of disciplinary experiences in geography, geocology, geobotany, ecology, landscape architecture and planning, converge in the direction of landscape ecology, and find landscape as a common meeting place. Several definitions of landscape emerge from all these approaches, as reported in Farina: [6]

- “the total character of a region” (von Humboldt);
- “landscapes will deal with their totality as physical, ecological and geographical entities, integrating all natural and human ('caused') patterns and processes ...” (Naveh);
- “landscape as a heterogeneous land is composed of a cluster of interacting ecosystems that is repeated in similar form throughout” (Forman and Godron);
- “a particular configuration of topography, vegetation cover, land use and settlement pattern which delimits some coherence of natural and cultural processes and activities” (Green)
- “a piece of land which we perceive comprehensively around us, without looking closely at single components, and which looks familiar to us” (Haber).

All of these definitions move across several dimensions in which landscape can be described, with the more cognitive-oriented ones (such as Haber's) resulting in broader visions that are able to bypass the

concepts that might classically be viable for public administrations to enact their policies and strategies, and to produce a more fertile humus for creation of a significative description of the planet which is able to include expressive and performative possibilities for humanity.

The concept of cognitive landscape, and of its possible contaminations through technologies and the results of the more advanced contemporary research in urban anthropology, has been a fertile domain for discussion during the initial phases in which we gave shape to the concept. A cognitive landscape can be thought of as the result of the mental elaboration by every organism of the perceived surroundings. [7]

We decided to contaminate the observations found in Farina's analysis of the theory of cognitive landscapes and of the mosaic theory within Clément's idea of nomadic observation of a constantly mutating environment, by focusing on the value of being able to recognize and understand the fluid and ever-changing natural ecosystem in a process that is inclusive, collaborative and disseminated.

In this mindset, we described a series of objectives, which later formed the concept for Leaf++:

- to create a tool for vision or, even more desirably, a new or mediated vision;
- to create an accessible and natural interaction metaphor, as close as possible to the practices to those which we are accustomed to; one which is easily executable by a wide range of persons across cultures, age groups, skills;
- to create an open platform so that it will, in and of itself, create an active ecosystem of practitioners wishing to use and modify it to enable more practices and possibilities for vision, awareness, understanding, expression and ubiquitous knowledge sharing;
- to create a usable information and interaction layer that is easily hooked onto the elements of the natural environment and that is accessible through mobile devices;
- to create a process which harmoniously conforms with the processes of our vision; just as we interpret what we see geometrically, symbolically, culturally or through our memories, experiences and relationships, Leaf++ should progressively populate our mediated field of vision with aesthetics, information, knowledge, possibilities for relation, understanding and interaction, just as details progressively emerge while we look at things;
- to create an aesthetic, sensorially stimulating, cognitively suggestive experience; one which is able to trigger wonder and emotion, to inspire action and participation, to activate cultures and open dialogues.

Along the lines defined by these objectives the research group set forth in designing the experience which was to be then implemented. The most pressing point turned out to be one regarding the ability to characterize Leaf++ as a "vision." Current Augmented Reality (AR) systems did not completely satisfy us with their interaction metaphors and in the composition of their interfaces as most of them heavily relied on movie-generated ideas of what an augmented reality interface should look like: radars, sonars, floating icons and other visual assets seemed to create videogame-like experiences that, while being usable and (in some cases) wonderful to look at, did not match the feel and aesthetics of the "new vision" which we wanted to produce. Our desire was to create a lens, a see-through transparency onto which the additional information layer would visualize in the most natural possible way.

Another pressing characteristic to be researched was the bypassing of the limits imposed by GPS driven augmented reality systems and to create an experience that was strongly based on (computer) vision.

One of the objectives which we regarded as being not only strategic but also fundamental in promoting the vision which is defined by the Leaf++ project was the requirement for openness of the technologies used and produced in the process. Due to this consideration the research team opted not to use any of the existing commercial (even if free) platforms that are currently available to perform computer vision based AR. We chose to develop our own technology and to release it for open usage to the international scientific and artistic community (the source code of all software used in Leaf++ is currently available on the project's website under a GPL3 license). The production of an open, working platform is, in fact, one of the most outstanding results of the project, and it fully supports the idea of open, accessible knowledge which we tried to enact in the natural ecosystem by engaging the making of Leaf++.

During the second phase of the project, the technological architecture was defined.

We chose to develop a mobile AR browser with the characteristics defined during the previous stage. The chosen mobile platform was developed for Apple's iPhone, mostly due to the availability of a stable development environment and for its ease of use – to satisfy the requirements in terms of accessibility and usability – and due to the availability of multiple international development groups dealing with computer vision issues such as the ones involved in the project, thus allowing us to establish an effective mutual collaboration which proved to be both effective and rewarding.

The platform which was created for Leaf++ is composed by the following elements:

- a trainable computer vision module
- a multimedia CMS (Content Management System)
- a service infrastructure

A computer vision (CV) module is used to provide image recognition features to the system. The CV module uses SURF (Speeded Up Robust Features) algorithms and techniques to identify the various types of leaves. The SURF image detection techniques and descriptors described in Herbert Bay, et al. [8] are used in the system together with a customized version of the optimizations described in Maha El Choubassi and Yi Wu. [9]

Specifically, the CV component is integrated in a system enacting the following process:

- image acquisition
- generation of feature descriptors
- classification and initial configuration of the CMS

A guided procedure allows the user to capture all the images that are required to correctly identify the relevant visual features of the leaves that are to be added to the system. In the next phase of the process an interface is used to navigate the groups of images of each feature and to use them in generating the SURF descriptors that will be used in the end system. Each descriptor uses information captured by the images as suggested in [8] and [9] to create the data that is needed for the realtime image recognition process. An initial version of the descriptor is generated automatically and the user is guided through a series of iterations whose objective is to refine this initial information, thus producing a better, more efficient, descriptor: by iteratively modifying selected parameters, and using the leaves in front of the camera, the expected results are compared to the effective ones, thus identifying the needed modifications to the descriptors.

At the end of the process each one of them is associated to a series of keywords establishing a taxonomy whose nodes are associated to the visual elements of the various types of leaves.

This taxonomy is used in the CMS. The CMS is implemented using a customized version of the Wordpress content management platform. The taxonomy produced in the previous phase is reproduced inside Wordpress under the form of a “customized taxonomy”. Using the standard features of the CMS it is, thus, possible to associate multimedia content (videos, sounds, texts, documents and interactive experiences) to each part of the taxonomy and, therefore, to the visual elements of the types of leaves that have been added to the system.

The service infrastructure is used to bring all parts of the system together for the usage experience. A series of software components that can be readily integrated into iPhone applications connect to the device's webcam and enact the realtime feature recognition process. When a leaf is recognized, its identification is translated into a series of terms in the custom taxonomy and relevant content is fetched over the network by interrogating the modified Wordpress CMS. The multimedia assets are then progressively shown onto the smartphone's viewfinder, coherently with the realtime onscreen position of the leaf.

Results

Leaf++ has proven to be effective in realizing an experience in augmented vision, applied to the possibilities offered by creating augmented reality layers of information and interaction onto the natural environment. The open platform produced during the project is currently being used for two specific purposes:

- an education platform
- an art performance.

The education platform enables teachers and students to add information about the plants in their environment directly onto plants' leaves. This allows all subjects involved to create ubiquitous education, knowledge sharing and information dissemination processes. At FakePress Publishing we are currently using the platform to create ubiquitous publications on the themes of ecology, sustainability and food and dietary education, producing information facilities that are ubiquitously accessible about the natural seasonal availability of vegetables, their origins and characteristics, creating enjoyable, suggestive and interesting ways to re-connect with the knowledge and traditional wisdom about food and environment which is progressively being lost in our urban ecosystems.

Leaf++ is also being used for the execution of an art performance in which the system is not connected to a set of databases containing information but, rather, to a generative audio and video engine. In this “concert for augmented leaves” the performers use the leaves in front of cameras to generate suggestive audio and visuals. The performance is currently being developed into a fully participatory experience in which the audience takes the role of the performers and is free to move around urban space and generating the audio and video collectively, by augmented-looking at the leaves that come across: a concert in the Third Landscape.

WIND, RAIN, AND PROLIFERATIVE PRESERVATION

Jon Ippolito

Generally considered a culprit in the destruction of traditional human artifacts, nature may end up serving as the inspiration for such new automated paradigms for the perseverance of culture. Yet, as successful as genetic algorithms are in preserving the information stored in the DNA of living creatures, harnessing genetic algorithms to propagate human artifacts would breed a new host of ethical questions about authenticity and responsibility.

Fig 1. Karl Sims, Evolved Virtual Creatures

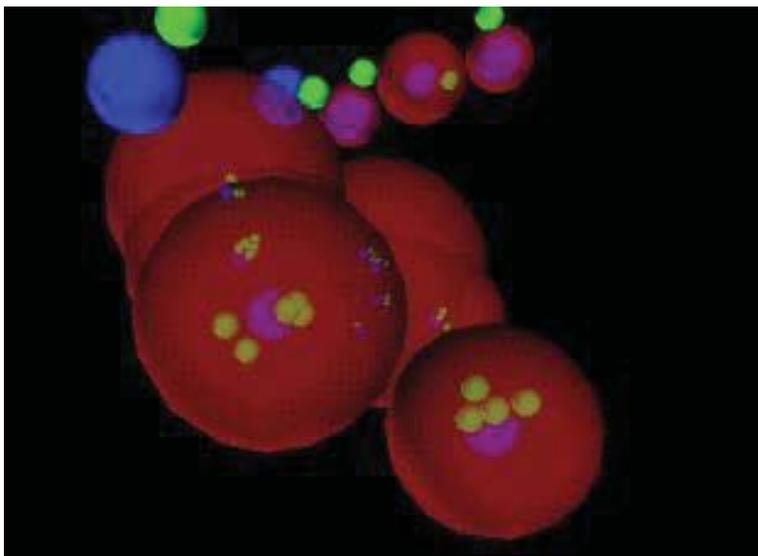

Fig 2. Tom Ray, Tierra

“If you take the Christian bible and put it out in the wind and rain, soon the paper on which the words are printed will be gone. Our bible is the wind and rain.”

--Salish elder [FN]

The organic archive

The word “archive” usually brings to mind hardware—shelves of solander boxes, racks of server boxes—or software—arrays of bitmapped images, frames of digital video, folders of Word documents. This paper considers the potential for an archive based instead on wetware—one that imitates the algorithmic processes of biological perserverance, if not its actual membranes and mitochondria. An organic archive would preserve via unorthodox processes like genetic replication and mutation rather than storage and migration. So it’s worth speculating whether organic processes might help preserve information-based culture in all its forms.

Digital tools like GarageBand and GIMP may grant today’s remix artists the power to proliferate culture, but this power pales by comparison with the fecundity of genetic processes. From natural ecosystems to synthetic genomes to genetically engineered algorithms, evolved systems are able to calculate, create, and copy with a robustness that remix culture cannot match; given the new millennium’s obsession with genomics and biomimicry, evolutionary paradigms are likely to play an increasingly important role in many disciplines in the coming decades. Our individual memories are organic, after all—why shouldn’t our social memory be?

DNA as archive

Archives that live and breathe are the beneficiaries of evolution, which is the tendency for natural processes to promote stable structures. As a consequence, an organic archive doesn’t need conservators and librarians to tend it, but given the right combination of energy and nutrients can reproduce itself. Artists like Joe Davis have already begun exploiting this fact to preserve rudimentary artworks via biological replication. Working with researchers at the Harvard Medical School and University of California at Berkeley, Davis encoded a Y-shaped symbol for fertility into DNA, and then inserted this “info-gene” into the chromosomes of otherwise ordinary *E. coli* bacteria. Left to reproduce in test-tubes in a lab, Davis’s microscopic studio assistants soon reproduced billions of copies of this rune simply by dividing and making more of themselves. “I’m the most published artist in history,” said Davis. [FN]

So what if you want to preserve an entire collection, rather than a single work? In a 2007 conference at the University of California at Berkeley organized by Richard Rinehart on “New Media and Social Memory,” Stewart Brand and Kevin Kelly suggested that we might encode the Library of Congress in DNA [CK]. This proposal is essentially Joe Davis’ infogene writ at the scale of an archive rather than an individual artwork.

DNA has shown potential as a computing medium for parallel-processing [FN: Square roots], to be sure, but a vat of DNA has a mind of its own, and is unlikely to treat cultural preservation with any more respect than it treats blue eyes or other desirable condition. DNA is transformative—partly via mutation, partly via sexual reproduction—and this fact is essential for its role in evolution.

That makes trusting preservation to an actual organic system is a dicey proposition. Of course, you could try to preserve the Library of Congress in a jar of DNA that's frozen; this would prevent it from mutating very much but not be a big improvement on storing it on a hard drive. To harness the power of an organic archive, you need to harness evolution's power to proliferate, which means either trusting replication to an actual organism (like Joe Davis's *E coli*) or an artificially stimulated evolution using manual processes such as polymerase chain reaction or exposure to ultraviolet radiation. In this case, a strand of DNA encoding a bitmap of the *Mona Lisa* wouldn't sit still in a vat of genetic goo, but would unzip and zip its halves promiscuously with other strands, replicating and mutating.

Synthetic genomes

Of course, it usually takes a lot of time for nature to evolve stable systems. Yet if evolution is really the cause of organic stability, then time measured in years or millennia is less relevant than time measured in generations—for it is by mutation and testing that organic stability arises.

Fortunately for future preservationists, not all evolution has to happen on glacial time scales. The short lifespan of the fruit fly favored by genetic researchers, *Drosophila melanogaster*, is compensated for by its precociousness, with the result that geneticists have been able to observe evolution at work in the laboratory because each new generation only takes a week to mature. As exciting as it may be theoretically, encoding cultural data in a genome is rather impractical. It's not trivial to extract the DNA of a fruit fly just to look up *Moby Dick* in the Library of Congress, much less to figure out whether its words have mutated along the way.

There's a much less messy way to exploit genetic proliferation. Researchers have experimented with digital equivalents of such fast-breeding organisms, called genetic algorithms. And they have gone further by setting the parameters by which such virtual creatures evolve. Such "fitness functions" vary depending on which traits the researcher wants to encourage. Might it be possible to design such a fitness function to encourage the perseverance of digital culture?

Fitness functions

As in so many radical approaches to preservation, artists were there at the outset. To create his *Evolved Virtual Creatures* [FN], artist Karl Sims used a random number generator to create mutations in a series of boxlike shapes whose movements and articulations were also determined by their genetic makeup. Sims then ran these creatures through a series of tests, each corresponding to a different fitness function: Which creature could swim the fastest? Which could win a hockey game?

By breeding successful mechanisms together, Sims stacked the deck so that the winners in each category were more likely to pass on their genes to the next generation of creatures. To be more specific, as each creature was represented by a simple computer algorithm, Sims interspliced the formulas for these algorithms to produce new formulas that are in a genetic sense the offspring of the older algorithms. As a result after a hundred generations [FN: <http://www.karlsims.com/papers/siggraph94.pdf>], Sims' bizarre creatures could perform their tasks with recognizable competence—even though Sims never designed them to do anything except evolve according to a particular fitness function.

Of course, as intriguing as Sim's system is, it's less a means of preserving forms we already have than a means of inventing new forms—a sort of eugenics program for art. Fortunately, even if you don't want your artwork evolved by organic processes, they may still help generate the software necessary to preserve it.

Danny Hillis and others have experimented with similar processes to evolve useful software, such as word processors. [FN] What if such an evolutionary system were trained not to create a faster or more efficient word processor, but to create a more stable one, that could work in a wider variety of documents and operating systems? This strategy would shift focus away from preserving individual artifacts and toward setting up the rules necessary for evolving an ecosystem capable of withstanding unpredictable changes in technology. If the word processor is the figure, its technological context is the ground, and they must complement each other if the ecosystem is to endure.

We know how to write the figure—a word processor—with code. But how do you model the ground—those unpredictable changes in technology? We can turn to a helpful metaphor from evolutionary biology that explains how individual species and fitness functions interrelate: the Epigenetic Landscape. [FN:17]

Wind and rain

Biologists invoke the Epigenetic Landscape to depict the way the development of an organism can be subject to genetic and environmental forces at the same time. Imagine a stretch of land in which dramatic peaks and valleys have been formed by powerful seismic forces; different populations live in the various valleys of this landscape, out of touch with each other due to the intimidating ridges that separate them. In this visualization, seismic forces represent genetic influences, which tend to segregate species into incompatible gene pools; hence birds and reptiles can no longer mate, even though they evolved from a common ancestor. Nevertheless, the behavior of the population is not determined solely by this seismic topography, for rain and wind can erode previously impassable peaks down into humble hills more easily traversed by the landscape's inhabitants. In this metaphor, the wind and rain represent environmental influences, which tend to encourage the evolution of new species through dramatic climatic change. (Paleontologists hypothesize such a cataclysm to explain the sudden extinction of dinosaurs and diversification of mammals 65 million years ago.)

How might this abstract model be applied to evolve a more adaptable word processor? The organisms on the landscape—variations on word processors—might be interbred to produce new variations, and those judged best able to display various documents would pass their code onto the next generation of word processors. Meanwhile, in addition to a predefined set of technical conditions—from, say, a Wordstar file in Windows 3.11 to a NeoOffice file in Mac OS X—researchers might expand the test by adding some wind and rain—random samples from an algorithmically generated set of documents and algorithms. In this way, the resilience of display software could be tested against technical contexts that don't yet exist. [FN: Lanier]

The ethics of genetic preservation

This vision of self-evolving, future-proof artifacts is heady. But it's also hazardous, because it plays into our society's increasing reliance on genetic modification for innovative solutions without regard for the long-term effects. While pharmaceutical research has produced blight-resistant crops and new tests for

cancer, it has also produced suicide seeds and antibiotic-resistant germs. Genetic modification has had a similarly mixed effect on preservation. Scientists by 2009 had created a living clone of an extinct species by transferring cell nuclei from the preserved skin of an extinct Pyrenean ibex into the eggs of a contemporary goat. In the same year, however, the US Food and Drug Association approved the sale of the pharmaceutical protein antithrombin produced in the milk of genetically engineered goats—in effect, engineering a new species of mammal for the sole purpose of delivering cheaper drugs, a practice known as “pharming.” Given the limited resources on planet Earth, the fact that genetically modified creatures can often outcompete their natural cousins [FN: Wikipedia on Genetic Engineering] suggests that tampering with biological systems could reduce their diversity rather than amplify it. It may be that biotechnology does not support the **both/and** logic of digital proliferation but reverts to the **either/or** logic of analog space.

To harness the enormous parallel processing capability of a virus or cell is to play with fire; the same potential for explosive and unpredictable growth that makes genetic processes attractive as a preservation strategy also makes them a potential danger to existing creatures and their ecosystems. Critics such as Jeremy Rifkin question whether humanity is mature enough to wield the power of genetic processes responsibly, given their unpredictability and proliferative potential. Even technologists such as Bill Joy have expressed concern over the “gray goo” scenario, a doomsday endgame in which one species wins the zero-sum game of a planet with limited resources. In this hypothetical future, researchers accidentally unleash a self-reproducing, evolving machine or organism that overwhelms the natural (and possibly the built) environment, covering the planet with a kind of gray goo that obliterates the rest of the animal and vegetable kingdoms.

And what of the preservation of genetic artworks such as Eduardo Kac’s glow-in-the-dark bunny or Davis’s runish bacteria? Allowing them to breed uncontrollably in the wild may be the best way to promote their perseverance, but it accords these artists with a power far beyond what artists are accustomed to, even in the age of the Internet. Although the biotech industry would prefer we didn’t notice, genetic materials are among the most powerful “weapons of mass destruction” available today. So how could archivists exploit nature’s proliferative powers without endangering nature herself?

As important as the task of preserving human culture may be, we have already seen the effects of its being **too** preservable: landfills piling up with plastic toys and rusting automobiles, pharmaceuticals showing up in breastmilk, and space junk crashing down from orbit. In our experiments with organic forms of preservation, we should make sure that our zeal to leave behind a permanent footprint doesn’t end up squashing nature in the process. Sure, it might be possible to encode the works of Shakespeare into every schoolchild’s DNA for their future reference—but what unintended consequences might this have for our evolution and our planet? Even a self-evolving word processor, while it sounds innocuous, could mutate into a virus that overran every desktop on the Internet.

Emulating ecosystems

One safeguard that might be worth exploring is built into Tom Ray’s *Tierra* project, a self-proclaimed “wildlife sanctuary for computer viruses” that simulates evolutionary processes in software. By creating a virtual petri dish in which snippets of code can mutate and reproduce, Ray harnesses a similar power as artists like Davis or Kac, as he cannot predict the outcome of the microscopic orgy committed by his computer programs. For example, to explore their behavior across a range of silicon ecosystems, Ray built a system that allowed his viruses to email themselves from server to server across the dispersed

harddrives of his collaborators. Once set loose in this closed network, Ray's critters decided to circumnavigate the globe. Remarkably, they became a nocturnal species, always seeking the dark side of the planet where they could take advantage of CPU cycles left unused by a computer's sleeping user.

When challenged that he might be endangering everyone else's computer network if one of his viruses ever escaped captivity, Ray replied that the emails [FN: Synthetic Ethics] bouncing around between servers did not contain any code that was executable on its own, but only within the specialized runtime environment of the *Tierra* software architecture. To employ a term from contemporary preservation, Ray's critters live in an **emulated** world. Programs running in emulation don't have direct access to real hard drives; they just think they do. If I download a virus into a Windows emulator, it can eat up my emulated resources, but won't have access to my real resources if I don't want it to.

So it may be that combining the security of emulated environments with the power of genetic replication could provide a safe and powerful future for cultural preservation. Transgenic Canola plants engineered to outcompete their feral cousins have extinguished their competitors in the field [FN: Wikipedia ibid], but a genetically evolved word processor on one hard drive needn't automatically erase an older word processor on another hard drive.

Nature: from culprit to collaborator

It is hard to imagine nature playing a positive role from the standpoint of today's archives, with their banks of manila folders and solander boxes arrayed against nature's will to entropy. Yet in the long term it may be that archivists will no longer be able to resist letting natural processes in the door—maybe even the wind and the rain—either because of their amazing powers of perseverance, or because the artifacts under their care are increasingly created with such natural processes. At that point perhaps the archive may aspire, like so many of our current institutions, to find a way to cooperate with nature instead of working against it.

WET PAINT

Vicky Isley & Paul Smith (boredomresearch)

boredomresearch explore the natural progression from static imagery allowed by recursive technologies which enable data to remain liquid. The artists Vicky Isley and Paul Smith often think of themselves as employing computer gaming technology to create landscape paintings and life studies that move. In this paper the artists will discuss their computational systems which manipulate data chunks to produce a diversity of moving images.

Lost Calls of Cloud Mountain Whirligigs (detail), 2010, boredomresearch, software artwork, 60 x 49 x 2cm. @boredomresearch, courtesy of [DAM]Berlin/Cologne.

Introduction

Here we will discuss the impact technology has on our practice, breaking the stillness of static image creation as we respond to the unique potentials that computational technologies make possible.

We are artists not technologists and our practice is not situated on the cutting edge of technological innovation – it is however responsive to the new possibilities present in current technologies. We employ computation in our practice to extend the heritage of painting. Computation allows for the creation of artifacts that can remain fluid and open in contrast to the medium of paint that dries; becoming fixed and stable. There is nothing exceptional about our adoption of these technologies as they are now more freely available than the traditional tools and materials used by painters. We accept them as a natural and inevitable progression, but one that may require some new approaches to the creation of art.

Many artworks we make rely on the iterative nature of computing creating each frame of an animation just in time to be seen. This is similar to a game engine where each frame is created in response to the changing state of play. Another aspect of games is their use of AI to provide game play with a synthesized opponent. The artworks we will refer to here include the AI component without user interaction. The entities exist in a closed universe interacting with each other; each frame created as a consequence of these interactions. Like paint that never dries the canvas remains fluid and open, rearranging and re-

composing itself thirty times a second. Film and animation bare more in common with paint, in that despite being animate, each discreet frame remains stable, identical and loyal to the artistic choices of its author. In contrast each frame in our work lasts for a fraction of a second before being discarded.

THE RISK AND REWARD

This ability to break from the stillness of previous media offers us something fresh to explore. We are able to make life studies that incorporate and respond to the processes present in natural systems by modeling aspects of them in code. We first explored this in our computational work 'System 1.6' [1] where the behaviour of the forms bring a sense of life to the work rather than their visual appearance.

'System 1.6' uses artificial life algorithms to construct a live visual and sonic composition that is different each time its played. During production this required different considerations to artworks that remain constant as we were dealing with a composition based on probability and likelihood. There were many emergent properties occurring, not as a direct consequence of the coded instructions but from the complex interactions of a large number of autonomous bodies. Small changes to the code could trigger a cascade of unpredictable events giving results inconsistent with our artistic vision. The only way to be sure our modifications were effective was to observe the work, sometimes for hours or days. It was more a case of nurturing behaviour than creating it directly. The artwork was finished when we felt reasonably confident it would perform well over an extended period of time. 'System 1.6' could run indefinitely without the interactions repeating but the forms themselves remained constant. In nature, life forms gradually shift and change giving rise to the vast diversity that exists.

Our artwork 'Biomes' [2] contains creatures that use a rule based system to form intricate patterns on their bodies. The rules are generated randomly from a vast range of possibilities. During development we were keen to explore these possibilities over an extended time frame. The problem was only a small proportion of rules created patterns, of which even less were rewardingly intricate. To solve this we introduced a virus like component that would move around the world killing off creatures with non-intricate marks. The proportion of creatures with complex patterns increased over time reaching a plateau. From then most creatures exhibit a level of complexity defined by the virus's selective pressure; with the occasional simple one slipping through the net. The cost of limiting the work to only those creatures that have a certain degree of complexity is that some interesting but simple forms are lost; while some complex but unrewarding forms remain. This constraint did not stop the 'Biomes' exploring a huge diversity comparable to that which exists in nature.

We had shifted from making exact choices, describing precise qualities, to creating environments that nurture interesting forms and outcomes. The more freedom we gave the work the greater potential for interesting and surprising results but with increased risk for periods of blandness, or worse, collapse.

The 'Biomes' have natural cycles of activity, not dictated by us, but emerging from their behaviour. Normally this alternates from moderate periods of tranquility to intense action. Very occasionally a 'Biome' can fall quiet for an unusually long period of time. Creatures can develop motion paths bypassing the small part of their world that can be seen. If a number of creatures develop this trait it can prevent others entering the visible area, causing an ice age of inactivity, weeks can pass without a single machine being seen. Whilst interesting, this naturally occurring phenomena, may not make for a rewarding experience in a week long festival context.

JUST BREAKING THE STILLNESS

One of the greatest potentials of creating artworks that remain fluid and open is their ability to throw up the unexpected – injecting some surprise into work that would dull with familiarity. Surprise is a double edged sword. During the development of our artwork 'Lost Calls of Cloud Mountain Whirligigs' [3] we were surprised to find our flying creatures 'Whirligigs' all in a deep sleep from which they would never wake. The challenge we face is balancing the reward of leaving artworks open to change, without it being terminal. In 'Lost Calls of Cloud Mountain Whirligigs' we have chosen to blend together elements that remain open with those that are fixed; elements that repeat in regular cycles, with behaviours that will never repeat.

The 'Whirligigs' represent a study of a narrow facet of diversity – they live and die with each new family exploring a seemingly infinite range of song, colour, form and pattern. Because their ability to change is constrained, they will always look like 'Whirligigs'. Like the order of insects Lepidoptera which presents a vast amount of diversity whilst maintaining an overall visual consistency. Within this tiny slice of diversity there are more possibilities than anyone could view in a life time, even if they did nothing but sit and watch 'Whirligigs'.

In the artworks we have discussed here we have attempted to employ ubiquitous contemporary technologies to break the stillness of traditional forms of representation, whilst remaining true to a heritage of artistic practice that observes and is inspired by nature, its forms, behaviours and long term ability to change.

The medium of paint has given artists thousands of years of possibility. The comparatively new medium of computation now challenges artists to find meaningful and rewarding ways of incorporating its capacity to remain fluid in their practice. We continue to be excited by these possibilities and proceed to tentatively exploring this, as yet, scantily charted terrain.

FROM STILL TO MOVING: AN ALMOST INDISTINGUISHABLE MOMENT

Cynthia Lawson Jaramillo

I challenge the traditional definitions of photography and film through work that is situated in that very short moment when still images become moving and therefore not definable as just one or the other.

Furthermore, I argue that in this fast-paced era in which 24 hours of video are uploaded to YouTube each minute, that in-between moment has become almost indistinguishable.

INTRODUCTION

Analyses on film and photography often characterize the photograph as a still image and film as a sequence of images. [1] I challenge these notions through work that is situated in that very short moment when still images become moving and therefore not definable as just one or the other.

In this paper I specifically discuss the principal techniques I incorporate into my image-based works, such as digital and physical layering, which push each piece as far away from the “still image” as possible. I question our capacity to perceive slow changes and multiple temporalities through works that explore both. Furthermore, I argue that in this fast-paced era in which 24 hours of video are uploaded to YouTube each minute, we have lost our ability to slow down and perceive small changes.

The work of contemporary artists such as Bill Viola, David Hockney, and Hiroshi Sugimoto offer a framework for my own artworks which I describe as photographic works in motion, which exist more as time-

based media that incorporate photography as a vehicle for the production of images, and less as photographs that pause time.

CHALLENGING TIME AND SPACE

“Time has begun to be experienced as something infinitely elastic, in which the relationship between past, present, and future becomes open to human intervention. Similarly, space is no longer a static field that we traverse over time, but has become a medium to be dismantled and reassembled at will.” [2] The photography work that is here described challenges time and space, and often uses the camera as a tool to create process-intensive work that goes beyond a static framed print mounted on a wall. Specifically, as a time-based artist, I work with photography as a tool (and not necessarily a medium) to create works that push the traditional boundaries of space and time with still images questioning how “still” they actually are. Typically, photography that moves beyond the pausing of time, and instead extends or challenges it is then considered film. Sequences of images are described through the lens of film (and not photography) and are critiqued in that light. Furthermore, seminal works like Chris Marker’s “La Jetée” do not neatly fit into either photography or film. [3]

David Hockney’s photographic collages and composite polaroids from the early 80s were a testing ground for new possibilities in photography and for a lot of the approaches in the era of digital technologies (both in cameras and in software.) His 1983 work “Photographing Annie Leibovitz While She Photographs Me” is both exemplary of this experimentation as well as a criticism on “classic” photographs. The far right side of Hockney’s composition has a small square image that is the photo Leibovitz took of him. This juxtaposition illustrates Hockney’s argument that a “single-eyed photograph” (as he describes Leibovitz’s image) would never have the quality of a painting in “that you can go on and on looking at these pictures.” [4]

Hiroshi Sugimoto’s “Theatres” are a series of images produced by maintaining a long exposure while photographing a theatre during a film screening. The light from the film’s frames light up the space, and the screen is white. This series “runs counter to prevailing conceptions of photography’s relationship to instantaneity and to the photographic image as the record of a brief and transitory moment in time. Here the photograph is, in a literal way, the embodiment of temporal duration – in a manner that has rarely been so since the infancy of the medium – and equally it would seem to demand of the viewer a form of attention that also takes time.” [5] Are works like this one truly still or do they have an extended duration equal to the film captured?

Finally, Bill Viola’s “The Quintet of the Astonished” from his series “The Passions” is the perfect work to refer to the power of the still frame (in his case of slow motion video) as well as an expanded sense of time. Viola invites viewers to slow down their internal momentum, to pause and take the time to view his work that also takes time, since each video in this series has been slowed down – both a reference to painting from which the works are inspired as well as a refreshing critique of our moving image-saturated lives.

I have developed two techniques to challenge the before mentioned traditional notions of photography and to position it as a time-based medium (in which images are in between still and moving).

LIGHT BOXES

My works presented through light boxes are spaces captured over time through physically layered and transparent still images. I challenge the notion that “the photograph is thought to extract a moment from the flux of time, to cut out a slice of a time-space continuum and thus to have no duration of its own – in a sense a photography only lasts as long as we are looking at it.” [6] Furthermore, the work challenges the classic notions that in photography one experiences equilibrium of our physical world’s “rhythm.” [7] Instead, each layer may be a time-slice, yet the superposition of images onto one another breaks the neat slicing, and the viewer finds himself or herself in constant motion – moving from one layer to the next as they experience one space over time.

Sequences of images that could be collaged digitally to create one print are instead presented as physically collaged, almost sculptural, backlit objects. A photo shoot (in which I take several photos, spaced at even intervals, from one same location although without a tripod) then translates into several prints on transparent film. I document spaces over time and present these images layered one on top of the other (the most recent in time closest to the front), and with a sheet of acrylic in between. This materiality gives the work a physical depth representing its temporal depth (the longer the total time captured, the thicker the work.) The last (or oldest in time) image is printed on a milky translucent film that allows the passing of light without revealing the light source behind the images.

These works can be described as cubist in that they contain “what was really occurring when Cubists broke up an image into multiple perspectives, thereby presenting, at one moment, a set of views that would normally be viewed successively over a period of time.” [8] More importantly, it is in the relationship between the images (on various layers) that time is produced. [9]

This technique was developed after visiting Tokyo and photographing the rush hour chaos in the large train station Shinagawa. Upon reviewing my images (and frustrated that I did not have a video camera with me) I wanted to be able to represent this experienced motion through the still images and I first superimposed them digitally.

My practice intends to slow viewers’ sense of time by protagonizing the everyday as defined by transient space and make them aware of their own quotidianity. It is my hope that the viewer will reflect on their own existence, and become hyper aware of the small moments from which we now quickly disconnect: the stranger passing by carrying groceries, the voicemail awaiting to be heard, commuters rushing to catch the train. The places captured (airports, train stations, subway platforms, entryways) are spaces which exist solely as transitional spaces – they have no function other than to facilitate the flow of people from one point to another, and it is this flow that heightens the everyday quality of the works.

HIDDEN CHOREOGRAPHIES

In “Hidden Choreographies” (“Pompidou from Above, 6 ½ Seconds” and most recently, “The Shops, 96 Seconds”) I address the concepts of time and space in a single location. In multiple photographs, the repeated (and extracted) presence of figures in each frame demonstrates that these apparently different moments actually happened in the same place and at the same time. The chaos and complexity that one would not necessarily witness when viewing a transient public space, in which nothing seemingly happens, emerges through in the relationship between the images. Although shot in half-second intervals, viewers perceive the resulting piece through the expansion of time in transient public space. As de-

scribed by Michel De Certeau, “The act of walking is to the urban system what the speech act is to language or to the statements uttered.” [10] The urban landscape is continually in motion (via its pedestrians) and it is this motion that this work documents.

The second body of work in this project is the 36 prints from “The Shops, 96 Seconds #1-36”. These works are digitally collaged based on 42 original photographs taken in the span of 96 seconds from inside the Time Warner Center in New York City’s Columbus Circle looking down on one of its entrances. The repeated (and extracted) presence of some figures in multiple photographs connects the thirty six prints as a series and demonstrates that these apparently different moments actually happened in the same place and at the same time. This technique has been described as “collapsing the law of physics on the gallery wall” [11] and it is precisely the uncertainty of what is real (and possible in our spatiotemporal frameworks) and what is not that I aim to question.

In this series I am interested in photography as a way to capture moments and, through their representation(s), extend their time. The thirty-six images of the series are digital recreations. Each of forty-two original photographs was studied, from which “actors” like the woman with the seeing-eye dog were identified and digitally removed. Then, a base image was selected and used as a “stage.” Positioning the “actors” into several of their moments then composed each image. Each person appears where they were at some point during the photo shoot, but there are clearly overlapping moments. The viewer of the work is challenged to understand if people were digitally placed or repeated, or even if it was a staged documented performance. The resulting thirty-six images are the first of over a billion combinations of these “hidden choreographies” and it is this spatiotemporal transformation that shifts the series from a photo shoot about the everyday to something worth observing, remembering, and capturing. The collaging is what adds time to each print, instead of presenting the moments as “fixed, unmoving events that is the still photograph.” [12]

An important process in this work is that these moments are actually not choreographed but found. This particular series was documented because of my interest in the framing devices I saw through the lens (the revolving doors as interfaces between the inside and outside.) Only once the images were in the computer did I select the protagonists of the work and found those moments that make the work interesting. The series is organized very specifically – first the empty stage, then a base stage common to all following images (with some people static), followed by the introduction of each actor – the woman with the straw hat, the janitor pushing a trash bin, the woman with a shopping cart, the tourist reading his guide, etc. Once all actors are introduced, they are combined in a variety of ways creating overlaps of time and space that didn’t actually take place, but could have, such as the power mom with the stroller bumping into the blind woman with the seeing-eye dog.

In both “Hidden Choreographies” series, viewers have expressed perceiving contrasting concepts. On the one hand there are those who feel that the repetition of the people walking through emphasizes the quotidian in their actions, and the meaningless of each. Others feel that the repetition, and the extraction of select pedestrians as “actors” gives them a certain protagonism therefore heightening the importance of their everyday activity (walking home, going grocery shopping, meeting up with a friend.) I have been asked if the work is based on a particular piece of film or theatre. Although it is not, I do see a connection with Francois Truffaut’s “Day for Night” in its opening scene, in which he is directing a movie and staging an ordinary city scene (pedestrians on a street walking, cars driving). You’re seeing a film within a film and are very aware of the staging of pedestrians, cars, and their movements & interactions in public space. The other film to which I see a reference is Jacques Tati’s “Play Time” in that it follows one man (potentially the “Man with the Red Suitcase” from my “Pompidou from Above, 6 Seconds”) in

spaces of a city and the choreography of that movement in relationship to the built environment. Of my first series, gallerist Christina Ray has written that it has “no start, no finish, and no story. The artist simply stops time, putting a six second hold on the public and then releasing it to dissolve back into individual realities.” [13]

This kind of work, if presented on a timeline (on video or in Flash, for example) would directly reference cinema (short animations, or even the more recent animated gifs) and even Muybridge’s early photographic experiments. It is of interest, however, to challenge definitions of time-based media. Can a work such as this one, that includes moments from across a timeline, and yet is not presented on one, be considered time-based? And as prints, does it fall under the category of still photography?

CONCLUSIONS

In the culture of interruption in which we live, many people have lost the ability to sit still and lend their time to still and slow-moving images. Younger generations are growing up in front of interfaces in which messages from at least four sources are constantly streaming in and fighting for their attention. As an artist I am committed to promote an internal slowing-down of art viewers’ momentum by creating works that contain a duration which require a similar time commitment from the viewer. Digital and physical collaging have served as my principal techniques to create still works that are in constant motion, and which challenge the traditional expectations of photography as a medium that pauses time. My light boxes and printed series exist in the moment in between moving and still images, and my hope is that that moment regains the spotlight and that viewers may be able to be still and really see what is in front of them, one frame at a time.

TECHNOLOGIES OF MEDIATION AND IMMEDIATION

JANIS JEFFERIES

The word medium, media and mediation, have a strangely double aspect. On the one hand, a medium acts as an enabler connecting things that might otherwise be completely disjointed. On the other hand, a medium is something that palpably stands between.

The word medium and its cognates, such as media and mediation, have a strangely double aspect. On the one hand, a medium acts as an enabler, as a bridge, connecting things that might otherwise be completely disjointed. On the other hand, a medium is something that palpably stands between. Mediated experience is always second-hand; mediated experience is, by definition, not immediate.

Even air as a medium through which we apprehend the World distorts. David Hockney, the painter, was concerned about this aspect, for example. In the late eighties he preferred photocopiers to cameras as he felt that the images produced by the latter were largely pictures of the air between the camera and the subject.

ECOTOPIA, TOWARDS AN ECO-SOCIO-MORPHOLOGY

Bin Jiang & Sara Franceschelli

This paper presents a urban design project of insertion of a restoration system into the city to accelerate recycling and regeneration of the system. This restoration system consists of a series of eco-machines which are not isolated from each other but are making up an “eco-tribe”, that could rehabilitate the urban ecosystem with eco-technologies and eventually could be integrated into the urban environment.

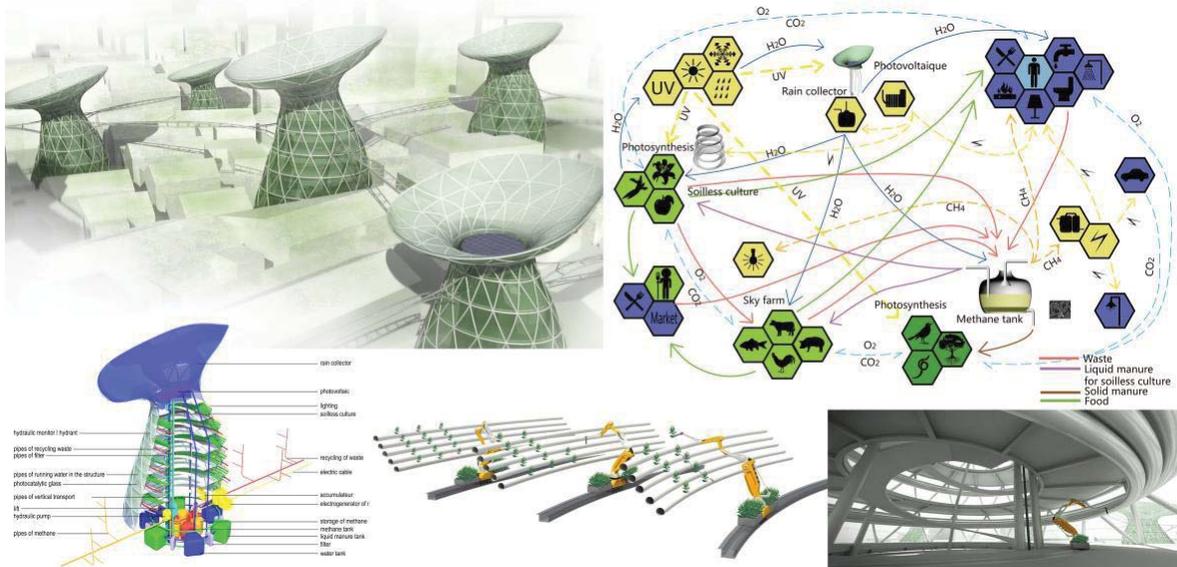

Fig 1. ECOTOPIA, 2008, digital image, Copyright Bin JIANG.

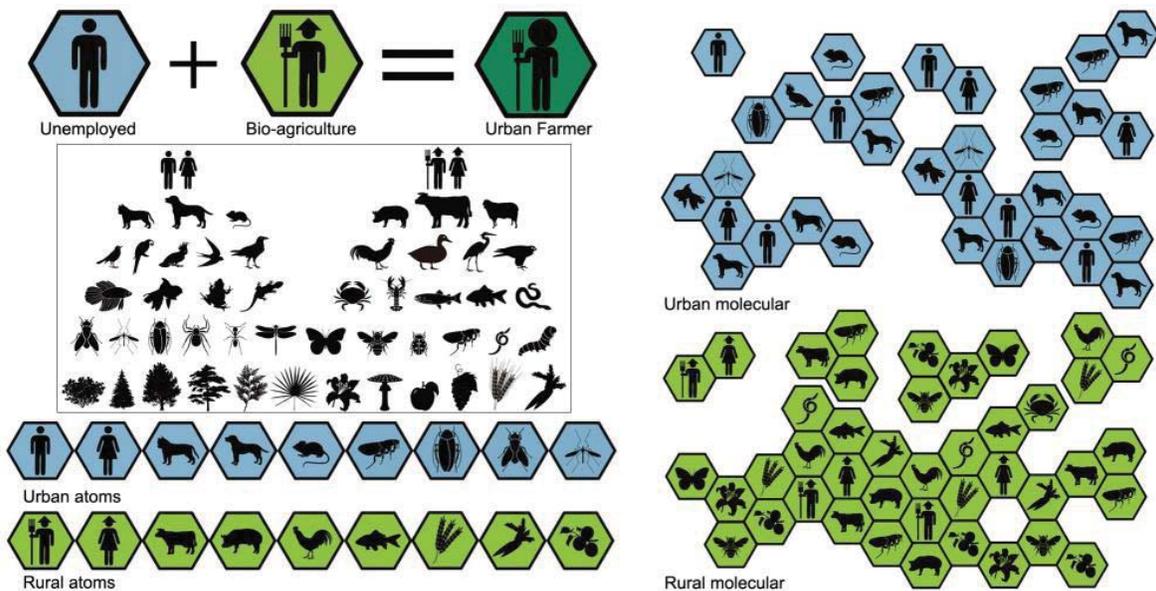

Fig 2. Semiotic system of ECOTOPIA, 2008, digital image, Copyright Bin JIANG.

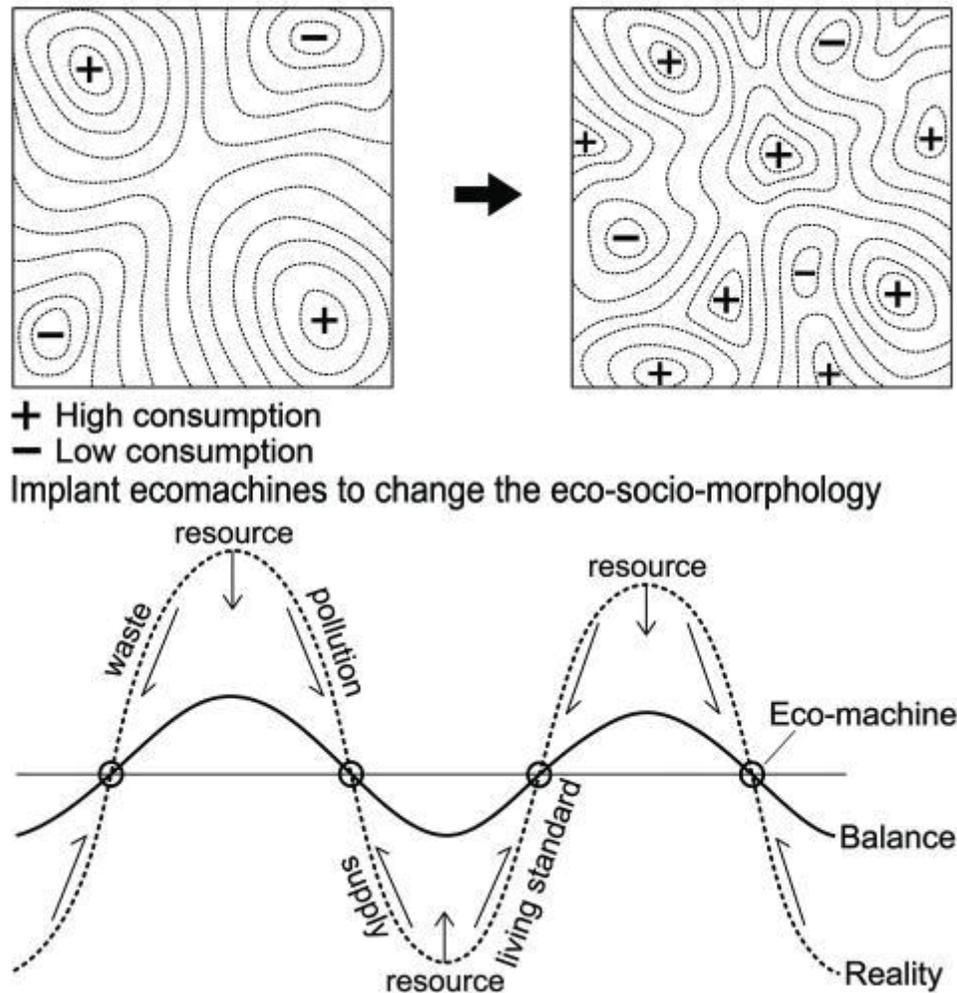

Fig 3. *Implant ecomachines to change the eco-socio-morphology*, 2011, Copyright Bin JIANG.

Today the ecosystem is suffering serious damages, due to the unbalanced state provoked by human intervention. This is the starting assumption of this paper.

We are first going to illustrate the ECOTOPIA project proposed by Bin JIANG in 2008. [1] The idea of this project is to insert a restoration system of eco-technologies in the interior of the city, where the living environment is deteriorating, in an attempt to accelerate the system's recycling and regeneration. This restoration system has been proposed together with a semiotic system, interpreting the relationship of various representative organisms in the urban, rural and wild environment. We will present the functions and the advantages that such a system should possess.

Secondly, in order to question and develop this proposition, we are going to formulate the working-hypothesis that the restoration system could be seen as a network of dynamical perturbations injected at a certain scale into the city, intervention that could modify the ecosystem of the city as a whole. We will develop this idea on the basis of a structural – although dynamical - interpretation of the metaphor of landscape, coming from theoretical biology. Without taking into account the semantic connotations that could be associated to this metaphor, in the context of theoretical biology. We consider looking at the initial ECOTOPIA project, structural and morphological properties of landscapes.

The Gaia hypothesis, [2] a theory announced by James Lovelock in 1969, but also exposed by Johannes Kepler in the 17th century, alleged that living organisms on our planet worked according to certain self-recycling rules which can satisfy their own needs within a gigantic organism called Gaia (named after Gaia, Greek goddess of the Earth). Two centuries later in 1924, this theory got backed by the concept of “biosphere” [3] raised by Viadimir Vernadsky who had also realized for the first time the undeniable connection between deforestation and climate.

The natural ecosystem possesses certain self-restoration abilities and this kind of restoration needs a certain period of time. The traditional agricultural production is based on cycle of nature and natural resource processing, which is a mode of production conforming to the nature’s rules. On the contrary, we have entered into the industrial era which is developing at fast pace. Under such circumstances, the pressing production cycle does not allow the necessary duration for the nature to restore itself, which means that the producing capacity of the industrial society has gone far beyond what the nature can bear. In the long run, the serious ecosystem imbalance is inevitable.

The industrial production can devour natural resources of huge volumes in a short period of time and furthermore, it can change chemical structures or biological genetic structures of natural materials. As a result, the nature is also overwhelmed to achieve the self-restoration in time. Though some damages are irreversible, at least during one generation, the project of inserting urban ecosystem into the global natural ecosystem as a part of industries, could make a change. The industrial society and the environmental pollution actually coexists with each other inseparably. Without any doubt, the problem of pollution arises along with the rapid development of industry.

The ECOTOPIA projet intends to insert a restoration system into the high density city. The leading idea of this project is that the eco-architectures forming the restoration system should be curative, intervening as living machines. They should be inserted into cities and be interdependent with each other, in order to develop sustainably, as in a transplant of new artificial organs to a withering ill body. [fig1]

The idea is to bring the eco-agriculture into the city as a treatment measure, in another words, to insert the eco-agricultural system into the urban ecosystem as a restoration therapy in order to cure the industrial society by the agricultural production.

This restoration system consists of a series of eco-machines which are not isolated from each other but are making up an “eco-tribe”. This could rehabilitate the urban ecosystem with eco-technologies and eventually could be integrated into the urban environment. The organized restoration system is a breakthrough from the existing patterns of the community, simulating the operation of natural ecosystems, will be inserted into the wrecked urban ecosystem and connect all communities to take effect in the range of the whole city. With self- reproduction and duplication, the system could constantly grow and evolve along with the city’s development and technology innovations.

Le Corbusier said: “The architecture bears living organisms.They present to the space, the light, ramify themselves and extend as a tree or a plant.The freedom is researched around each part.” [4] My design concept for the eco-architectures is derived from the sea anemone structure. The unit of the system is a kind of recycling tree tower, called “Sky farm”, which seems like a stretching sea anemone facing towards the sun. It will be inserted into the existing communities. In the high density city, it is difficult to find much available ground space; therefore, I choose to develop the agricultural cultivation in the vertical space. Each tower, at a certain distance from others, is connected by an overpass in the sky which exchanges energy and materials. Several tree towers form an Eco-tribe whose unit is community. In this

way, these implanted eco-agricultural machines not only could resolve many environmental problems such as reducing the emission of CO₂ and other harmful gases, eliminating organic waste, supplying clean water sources and energy, but could also satisfy food demand of community residents directly. As a result, these eco-tribes and local communities could make up a brand new harmonious and efficient eco-community without pollution.

A semiotic system interpret the relationship and composition of various representative organisms in the urban, rural and wild environment, is introduced. In order to present this semiotic system, some definitions will be useful. [fig2]

Natural Ecosystem: The biosphere is a kind of global self-sustained ecosystem. It integrates all the living organisms through various biological chains and classifies them into 3 categories: the lithosphere, the hydrosphere and the atmosphere. All of nature's movements alter the appearance of our planet by ceaseless circulation and recombination of elements.

Urban Ecosystem: The human activities have been changing the earth's appearance. Cities have come into being along with the concentration of population. In the same way, other living beings in cities have gradually altered themselves to adapt to the urban living environment. The urban ecosystem exists as an artificial link in the whole natural ecosystem and has the great impact on the latter one.

Rural Ecosystem: The rural area is a buffer zone between the natural and the urban ecosystems.

In the semiotic system introduced together with our eco-architectures, different organisms are symbolized by a representative atom. In the urban environment, residents, domestic animals and other smaller parasites relate with each other, building up an urban molecular chain. These chains combine together, engendering more complicated and gigantic compounds among which the biggest one is the social system. As for in rural environment, peasant is the basic atom, along with farm animals and agricultural plants, composing the rural molecular chains and their compounds. While in the wild natural environment, the basic unit is trees, which constitute the natural ecosystem with other wild animals, plants and insects.

On the basis of this semiotic system, some more general 'equations' can be imagined, that should define and produce the constitution of the Eco-city:

- Architect = Organizer of the production
- Architecture + Eco-technique = Eco-machine
- (Eco-machine + Bio-agriculture + Urban farmer) x n = Eco-tribe
- Eco-tribe + Existing Community = Eco-community
- Eco-community x n + Eco-system = Eco-city

The constitution of the Eco-city should perform the following functions:

1. Developing the urban eco-agriculture and restoring the urban ecosystem .
2. Initiating the system operation with the solar power in the early stage, and then maintaining the system and the supply for communities by bioelectricity: first, recycling sewage and organic waste produced from daily life and agricultural production; using the waste liquid from the methane reactor as the nutrition of soilless cultivation and livestock feed, while the waste

residues as fertilizer of public green space; generating electricity with the clean methane to meet the needs of household fuel gas, public illumination, power supply for the electricity bus and so on.

3. Sky farm: introducing the bio-agriculture, soilless cultivation, livestock breeding in a vertical space, perfecting the urban biological chain and supplying predominant food.
4. Lighting of the farm: the loop bracket of soilless cultivation turns around driven by electricity, like a revolving restaurant, in order to let all crops receive light evenly by adjusting the way of revolving and its speed according to seasons and time.
5. Tree towers with water line in them constitute a group of fire control towers in the high-density community, ready to alarm and fire-fight any time; possible to spray water directly from the tower to the house on fire or draw the fire-fighting lance to put out the fire.

The fact of transplanting countrysides in the city should provoke a restructuration of the society frame. The eco-community alters the former concepts of community, unifying the traditionally separated communities and promoting the trans-community exchanges. In addition, insertion of the eco-agriculture into the city will result in a new social type called "Urban farmer". Thanks to the leverage effect of eco-technologies, fewer farmers could provide more products, compared to the traditional agricultural production. Furthermore, the urban farmer also shoulders the responsibility of maintaining the virtuous circle of urban ecosystem.

On the other hand, the popularization of urban eco-agriculture, as a vivid textbook, would facilitate those who grow up in the city to approach the nature and comprehend the movement of natural ecosystem, thus make them realize the importance of protecting the nature and restoring the urban ecosystem to intensify their sense of belonging to the nature.

How do these desiderata can be realized? Are these 'equations' producing the emergence of new, balanced, equilibria? We think that the design of such an eco-city should comprise an analysis of the balances of the different, unstable equilibria in town. How to we switch from the point of view of the designed objects and their functionalities (expressed by the 'equations') to the point of view of the resulting equilibria in town? We follow here a line that takes into account some aspects of the figure of landscapes in theoretical biology, discussed in the framework of the Dynlan-Dynamic Landscapes research program. [5] In our research program, we are interested in the structural, although dynamic properties of landscapes. Thus, even whether we refer to images coming from the history and the theory of contemporary biology, we do not consider the semantic connotation of these figures in their original contexts. We consider them as structural dynamic images that can help in asking questions and setting scenarios. We are encouraged on this way by the structural and holistic attitude that moved Conrad Hal Waddington in the introduction and heuristic use of his image of epigenetic landscape. [6] For example, Waddington could introduce the notion of genetic assimilation on the basis of both of his experimental work and of the potentialities of landscapes images. Of course, even in our case, this work of abstraction is a first step of the research, and should be accompanied by empirical, situated, studies.

With the help of the hilly surfaces of landscape images, we want to move our discussion from the plan of the project ECOTOPIA in the actual space of the designed objects, the space of the city, to the plan in which the different equilibria. In order to grasp this second plan, we consider a metaphorical phase space. [fig3]

Could the global morphology of landscape, representing the global equilibria portrait, be affected by an external perturbation? How could one alter landscape equilibria, especially if they define too important

discrepancies between different consumption regimes? The idea is that the introduction of eco-machines as perturbations could modify the socio-eco-morphology of the landscape.

Inspired by the well-known image of Sewall Wright landscape, [7] here the idea is that the hills of the landscape should represent picks of higher or lesser consumption, a quantity that is both a socio and ecological indicator. How external, cyclic, autonomous but interconnected interventions could modify the global form of the landscape?

We use the landscape metaphor, as a heuristic tool, a mental image to help in reasoning. We are trying and look for balance processes in phase space as an approach to conceive an urban system able to actually produce these equilibria. In order to come back to the empiric world, with this hypothesis and questions in mind, and to evaluate the pertinence and the fruitfulness of this approach, at this step of our research we are exploring the field of studies from the territorialist school, [8] to the field of sustainable change researchs for example Babalis. [9] But we are also interested in the approaches that look at the town as a complex system and propose mathematical models and simulations. [10]

Eco-socio morphodynamics produces a modification of the landscape profil. In conclusion, we assume that the post-industrial society would completely enter into a new era of intelligence in decades when green technologies would become prevalent and the eco-agriculture would accomplish totally automatic and efficient production. Furthermore, the urban eco-community would be duplicated and extended constantly to maintain the urban ecology and the natural balance. In particular, the whole ecosystem could come into the virtuous circle.

A structural use of the landscape metaphor, suggests that morphological and morphodynamical aspects of the echo-city could be studied in the phase space, as a global approach to equilibria and changes in equilibria. However, in order to cope with complexity of eco-social system, we think that moving from the traditional hilly surface representing a landscape, to more plastic, morphologically variable objects, could help our future reflection.

E-PARTICIPATION - ENGAGED PARTICIPATION

Michael Johansson

At the “Collaborative media Lab” participants with a background in academia, design and in art, strated a lab to work with design of new technology and its application with a user-centered perspective in both real, virtual and mixed media settings. We point out the need for a more profound relationship when and where to use digital materials and tools and how to recognize and support participants in different kind of collaborations.

Three design environments - non 3d, michael johansson

At Kristianstad University the informatics group have founded the “Collaborative media Lab” including participants with a background in academia, design and in art. The aim of the lab is to work with design of new technology and its application with a user-centered perspective in both real, virtual and mixed media settings. Having worked with participatory design and 3D/virtual realities in several design/research project, we have seen the strength of collaborative design tools that allow newcomers to design and work with 3D. They were able to engage in designing in relation to rather complex scenarios and spaces, and in that way explore the design challenges that are offered in a particular context. This has typically been done in groups located and working together in the same room. But now with the social web including distributed and shared collaborative environments these setting can be used for engaging participants in a dialogue of future urban design challenges in new ways.

In our former research we gained a lot of knowledge and experience of how to use computers and software as tools when directing and conceptualize traditional productions, but we still have a lot to learn when it comes to seeing digital material as a design or artistic material in itself, especially in the area of collaboration. However it is not so strange, as digital design is not yet as mature as traditional design. Digital material have characteristics that differ a great deal from those with which most people are accustomed. Digital materials are usually more complex and flexible, less transparent and tangible. We have to point out the need for a more profound relationship when and where to use digital materials

and tools. We believe that increased complexity in creative development calls for both disciplinary depth and integrative skills.

E-participation is a way of letting the public into planning and decision processes. The keyword here is “processes”. Rather than e-democracy, e-participation is about creating dialogues, and being able to contribute with new suggestions and ideas. Working in the research field of design, we stress the importance to give the co-creators a common and grounded point of departure, as well as a common surface for interaction, communication and feedback.

We therefore use a mix of fiction and facts in our planning and writing process, to provide relevant and engaging background information. This is later are handed over as scenarios to the invited participants. The scenarios provide detailed and specific data, which then the co-creator can use as reference material for their future action. The scenarios acts very much as constraints, but also as a first generator in a chain of associative design work that follows, producing a shared proposals. Based on scenarios our model of exploration starts in a believably territory, were all of the co-creators put forward, experiment and establishing iterations between the themselves and the scenarios in a collaborative 3d setting. The scenarios. provide knowledge to the different stakeholders and influence their development using this shared 3d environment as the surface for exploring concepts and communicate them amongst the participants in an constant dialogue. A Collaborative 3d environment can be an effective environment for expanding ideas and gain a better understanding of the design task. Totally untrained persons are able to build rather complex spaces within short time limits. It is playful, fun and stimulating to use, promoted innovative thinking and in that way activating the design process. We have worked with similar question in many different projects. In an ongoing art and research project, the city of Abadyl we made these observations, that was descibed in an earlier Paper called Fieldasy.

The role of scenarios in design has been that of writing narrative descriptions of use. Other cultural domains have generated more speculative methods for collaboration. Originating from the idea of autonomous writing the surrealists borrowed methods from academic disciplines such as sociology, anthropology and psychology to elaborate methods in the form of games for exploring the mechanism of imagination and intensifying collaborative experience. They subverted academic modes of inquiry to undermine rationality and invented playful procedures to release collaborative creativity. The role of procedures and systematic strategies, while still being playful makes a creative constraint. Research on creativity points to processes, which not stems from a vacuum in the individual mind, but that they are a result of serious and known strategies. This applies to many aspects of artistic work. Changing a constraint might be at the core of creative thinking. Other researchers stress the process of association, how one item by acts of creative association creates a new item.

The scenarios acted very much as constraints, but also as a first generator in a chain of associative artistic work producing the artefacts.

We use written scenarios. These are handed over to the invited temporary citizens and co-creators. They can then act out the scenario, in and by themselves chosen environment that in the end helped them produce the artifacts. Our scenarios tries to bring field studies and fantasy together, to slowly create a discreet dynamic tension and/or displacement between persons, things, times, places, and events that are not usually - if ever – associated into new and surprising conjunctions. By using scenarios we are able to provide detailed and specific data, which the co-creator can use as background material for their action. Hopefully the co-creator themselves imports qualities into the world, which do not and cannot stem from the City of Abadyl itself.

Example: An interview with one of the participators revealed that; "Imagination was tickled by the knowledge of being part of a networked mapping I didn't know in detail. The scenario got me going, but I felt no repressing obligation towards it and also felt more liberated that in the situations of my own work where I'm the responsible and potential object for critique"

By placing "hard-to-answer questions" in a scenario, where the respondent is not fully in control of or responsible for his or her actions, he or she can eventually take on responsibility for such questions and find ways and means to act out the given problem in a shared environment.

When we are involving participants in complex and/or controversial questions, in a shared dialogues about future issues, it is important not to forget to clearly state what level of influence their participation will have, and process wise, what kind of output, feedback and final result they can expect. Otherwise we will have people playing around with future emerging possibilities with no idea how it will be used or communicated.

Our conclusion is that this is due to the fact that E-participation and the actual design of virtual spaces can support participants and stakeholders to combine different ideas, negotiate and prioritize. In this way the shared environment deepened the understanding of designing in the context of future and complex urban spaces.

TOWARDS A TAXONOMY OF INTERACTIVITY

STEPHEN JONES

In this paper I take a critical look at the notion of interactivity; an inadequately defined term. It has very deep roots within the world, both as it self-organises and as we construct it. I offer an analysis of interaction based on the notion of “relations” as a general term for the interconnections through which all interactions occur. I examine the degrees of relations that operate so that information flow between entities is enabled.

When one looks critically at a great deal of the contemporary new media art that is described as interactive, one finds a huge variance in its formal manifestations such as

1. the form of the artwork and its technical constructs; *i.e.*, whether it is an installation or a performance, a sculpture or a software application
2. the location and accessibility of the artwork; whether it is standalone or networked, situated in public space or gallery space
3. the kinds of interactors; whether human or machine, audience or individual, or even computer to computer.

These kinds of categories constitute the taxonomy being developed by Katja Kwastek and visualised by Evelyn Munster for Ars Electronica [1] and no doubt others. However this kind of taxonomy does not investigate the actual processes of interaction itself, *i.e.*, it does not explore what happens in terms of the flows of information and signs between entities, human or machinic, when engaged in these kinds of interactions. It is the intention of this paper to develop, in a preliminary form, a taxonomy of the kinds of relations through which information and signs flow in the actual activity of interaction, where relations constitute the connections or linkages between entities.

Interaction – and its co-relative, participation – have a very wide range of structures. Interactive artworks occupy a wide range of levels between the potential fully conversational robot and the video replay that simply switches on when the spectator enters the gallery. These run the gamut from the 'interaction' in the mind of a viewer in their active mental interpretation with an entirely passive artwork (a painting or sculpture) through to detailed and creative conversation between individual people and possibly between people and machines. It is the notion of the conversation that for me constitutes the full concept of an interaction.

In order to come to grips with an understanding of interaction in contemporary art and its range from the entirely one-sided to the fully conversational, I want to assemble an understanding that is as general as possible, so that it is not restricted in its application simply to human-machine interaction, but is operational over the full range of processes that can be described as interactions, be these the exchange of chemical products between micro-biological entities or the possibility of having a truly conversational relationship with a robot in the way that you and I might interact when we are having a conversation. This generality should then allow us to go even further, to the point where we might engineer truly conversational relationships between machines. I use the term 'conversational' because it entails a notion of inventiveness, which we might think of as the capacity to generate new behavioural repertoire and by which we might be able to produce a true artificial or machine intelligence, *i.e.*, a creative machine, one

that can not only trick us into believing that it has passed the Turing Test, but can truly generate new and creative ideas.

Interaction implies reciprocal actions or influences of two (or more) entities upon each other, where an entity is some kind of organised object of multiple components that has some degree of autonomy and agency. Thus, interaction takes place between entities that possess the capacity to act for themselves. It also requires that these actions alter the internal (cognitive) structure of each. At the most basic level interaction is fundamental to life, since it is the means by which an organism deals with and adapts to its environment. [2]

While this paper examines the interaction between an artwork and its spectators, in general the entities that engage in this reciprocal behaviour may be biological, social or machinic. Of the biological, at the lowest possible level of entity are single-celled organisms, at the highest possible level are whole societies or even whole ecosystems, though I will discuss human organisms for the most part. Machinic entities are artificial or constructed, *e.g.*, technical and computer driven installation art, robots, and other forms of potential artificial intelligence. These devices must be, in some sense, adaptive, *i.e.*, able to change their state to accommodate changes in their environment. This is a necessary first condition that has to be possessed by any entity that will undergo interaction.

There seem to be two general terms that apply. One, participation, though not usually thought of as involving relations with some kind of machine or constructed object, may be characterised as one-to-many, and involves engagement with a group of others in an event of some sort. To participate is to place oneself in the context of some process and to engage with whatever it offers that allows some kind of entry into the overall event. One becomes part of some larger thing or event that is the participation, *per se*. These can be happenings, theatrical events, and events in which the spectator has to supply at the very least their presence so as to complete the work. There will be multiple processes of connection developing over time producing a wide spectrum of activities.

The other, interaction, involves engagement with, usually, a single other entity (person or machine), and is commonly one-to-one. Again the work is not complete without the interaction, but here the focus is on reciprocal relationships and their development over time. To interact is usually considered to involve engaging with devices of varying kinds through the exercise of controls or sensors or other data gathering attachments that provide information as to changes in local conditions, and thus permitting the spectator, as user, to participate in the process of some 'thing' so that some kind of reciprocal relationship develops with it.

A distinction is often drawn between participation and interaction. This has an historical basis in that the word participation applied to early (1960s) forms of happenings and other event based art, whereas an interaction is usually thought of as being between a computer-driven or other machinic device and a person. In English usage, one 'participates in' but 'interacts with' some thing. However, in both situations it is the coherence of some larger process – a product of all the entities involved and greater than each entity when each is seen as an individual – that one experiences. As Pask has noted:

“an observer who comes to know the system must be a participant in the system. The boundaries of the system, far from being pre-fabricated, are created by the activities of the system. This is a prescient notion of autopoiesis, or organizational closure.” [3, 353]

The use of the term 'participation' arose in the period of the happenings of Allan Kaprow or, for example, Nam June Paik's *Participation TV* (c.1963). Apart from the obvious person-to-person interaction required in a happening, I suspect that this distinction has lately been drawn through a need for a formal distinction between works produced through the use of analogue systems and works in which the computer is the locus of the choice-point selection process that is seen as interactivity in much recent contemporary art. Thus, participation and interaction can be shown to have a very similar set of characteristics whatever the technological means.

If participation was analogue and interaction is digital then given that they are both means by which one develops some kind of relationship with an other; be they animal, human, significant, analogue or digital machine (computer), environment or any combination of these, then are they not two words for the same thing? The key is that some sort of communication transpires; a reciprocal exchange of (generally 'meaningful') information that endures because of that meaningfulness and its reciprocation. Thus I argue that the separation between participation and interaction is meaningless, artificial, and misdirecting.

But what exactly are the processes of interaction? What are its characteristics? Firstly, whether the process is direct – through the exchange of chemistry (*e.g.*, in biology), or mediated – through language or any of the extensions of our capacities that are embodied as analogue or digital technologies; a body, or some material functional object the states of which are alterable, must be involved. Thus, interaction must be embodied. Interactivity, being medium independent, needs some sort of physical channel through which information transfer can occur. These channels function as relations to the other and could as easily be speech as they could be a camera sensing people walking into the gallery. Ultimately what counts is what is recognised in the sensing and that, like it or not, is analogue.

Interaction is the relational dynamics that occurs between an entity – an organism or device – and its environment.

An organism is any coherent biological entity that metabolises energy in order to maintain that coherence (its organisation) within an environment, to gather and process information about its environment, and to permit its reproduction. At the machinic level are devices that are in some sense adaptive, *i.e.*, that can change their state to accommodate changes in their environment. The need to be adaptive is a necessary first condition that has to be possessed by any entity that will undergo interaction.

An environment is all other organisms and the physical, social, cultural and machinic context that constitutes the experiential space of an organism for any duration. Every thing that is in some sense other to (*i.e.*, not) an organism is its environment. Only the most sterile of environments are entirely passive or neutral; thus interaction and its corollary, adaptability, are necessary for any entity that has to survive in an environment.

To any organism its environment is 'active' when other organisms interact with it by competing with it for resources or by generating outputs (signals) into the environment which may or may not be useful to it. Its capacity to adapt to changes in its environment is essential to its continued coherence and its reproduction. This adaptive capacity is tested by its capacity to use the resources in its DNA, or program, and its stored experience to handle day-to-day changes. But to 'know', in any sense, about those changes it must be able to sense its environment and effect internal changes that accommodate those

sensed external changes. These processes are structurally fundamental to interaction, and they constitute the primary level of the process of communication. [2] Further, they require the two orthogonally related conditions of 'autonomy' and 'agency'.

Autonomy implies that an entity can stand alone in some sense, making decisions based on its own knowledge of its situation. Its etymology is from the Greek *auto* for 'self' and *nomos* for 'law', *i.e.*, self-driven or self-governing and, thus, self-regulating. Based on this we might think of something like a static autonomy, for example an object such as a painting or a sculpture that is complete in itself, through to an active mobile autonomy best represented by a living organism that is capable of moving, feeding, sensing and, overall, making decisions for itself. The notion that a static object, something that just sits there and does nothing is autonomous seems trivial but it stands as the lower bounding case of autonomy. We normally think of autonomy as applying to an entity that is in some sense self-sustaining; that has the capacity to sense its environment, operate on it, and thereby make decisions for itself, and thus we start now to see a merging with the notion of agency.

Agency is that property of an autonomous entity that is its capacity to act in or upon the world. That is, having made a decision it has the capacity to carry out (or execute) that decision.

The kinds of entities that have both autonomy and agency will be both biological (living) and artificial (constructed), *e.g.*, robots and other attempts at artificial intelligence, and our chief interest here, installation artworks.

Adaptation by an entity to its environment both requires and supports its autonomy, allowing the organism to behave independently of other organisms, survive on its own and enact its own decisions. An organism's autonomy requires internal feedback relations in which aspects of its internal system can enact the regulation of its local environment in intentional ways. When these relations spread beyond the organism's boundaries you get social environments in which organisms communicate, sense and have intentionality and from this comes interaction. [4]

There are degrees of relations that may develop when a spectator encounters an artwork. These may manifest in several possible ways.

Degree 0: The artwork may be entirely passive and the only interaction is that process of the interpretation of an artwork that the viewer has to make to be able to see it and render it meaningful to them. Such action takes place entirely within the viewer, and although it is dynamic it has no impact on the artwork, which is itself entirely passive.

Degree 1: It may be triggered to start some playback of a pre-programmed sequence. Obviously interpretation on the part of the spectator is involved, but now the work becomes, in a very limited way, active. However there is no further impact on the artwork beyond the commencement of its pre-programmed trajectory.

Degree 2: It may respond with an action of some sort which will in turn draw further behaviour from the spectator. The artwork can now be said to be interactive. This is the common 'interaction' that occurs when the actions of a spectator elicit some sound, movement, visual or other event from the work that, *crucially*, causes the spectator to make further moves that are sensible to the artwork, thereby elic-

iting different sound or visual events from it. It is the kind of interaction that a musician has with an instrument, and the spectator may in fact be able to develop some skill with the artwork so as to be able to play it like an instrument. However here, the artwork's responses are all preprogrammed in the sense that a particular movement or action will elicit one particular response from the object, or may force a selection from several possible responses depending on, say, a contingent branch in the program flow.

Degree 3: If further movements of similar type are produced, a changing range of responses (*e.g.*, new sounds) may be produced, since, having made one response the machine may then 'know' to make a different, albeit preprogrammed, response when given a similar stimulus.

The above classification is not dissimilar to that of Cornock and Edmonds. [5] For them interactions could be:

1. static: allowing no opportunity for interaction
2. dynamic-passive: change in response to environment, but not influenced by users
3. dynamic-interactive: "generate outputs that correspond directly to input from audiences."

and more recently Edmonds, Turner & Candy's addition of the class: dynamic-interactive (varying): "distinguish[es] articles that change over time, either through automated learning or through updates from the artist." [6]

However they do not go far enough, thus:

Degree 4: By any measure the peak class of interaction is conversation – an ongoing, inherently stable, multi-sided, adaptive process of information transfer, that consists in alternating, reciprocal production and transmission of information and response to that information, through consideration, recognition (of signs), understanding (of their meanings), development or extension of 'ideas' embodied in the messages and the production of further transmissions. Conversation must involve understanding which is a function of a mutually agreed, or learned, set of signs (language) that convey the meaning.

Conversation necessarily involves feedback; the closing of the loop through the response by the second party, which is in turn considered and responded to by the first. Thus a continuing cycle of feedback undergoes temporal development as the conversation continues, and each party is, at least, able to utilise its existing repertoire of behaviours – ranging from language and gesture to the demonstration of objects and processes or the operation of machines. This cybernetic feedback relation, though largely neglected in contemporary art over recent decades, provides a framework of immense value in understanding how interactive systems can work, and it is the circular feedback system that renders the conversation something greater than what exists within each party, such that its coherence gives it a mutually embodied autopoietic presence.

More interestingly, in any intelligent entity (living or artificial) the learning of a set of signs to convey meaning will require the development of new behavioural repertoire through a process of adaptation. The interactive context (the environment) will make demands on each entity and place constraints as to the effectiveness of any behaviours, moulding the development of any new repertoire.

In sum, while none of this is strictly 'new,' little of it has been spelt out and incorporated into contemporary art practice. Pask's work would be the only counter example. Regarding conversation, and paraphrasing him [3, 358–360]:

1. Conversation between individuals occurs over time and alters the mental contents of each individual over that time.
2. Conversations have a start and a finish and unfold over time, although they may run in parallel, supposing more than two individuals are engaged.
3. The conversation is in the the union of the minds of the individuals engaged. That is, it exists as a superstructure that is not contained exclusively in either mind but necessarily is a function of the activity of both.
4. There is a process of feedback that gives conversation its unifying character.
5. There is a “transfer of tokens” (language, signs) between each individual within the conversation.
6. These 'tokens' must be mutually understandable. However, the interpretations of the conversation are nevertheless a function of each individual mind.

While many interactive artworks demonstrate some level of “reciprocal production” I know of none that have achieved a truly conversational level of interaction. This I suppose is due to the intractable problems of building a true artificial intelligence. One of the nearest approaches to this status is in Stelarc's work, the *Prosthetic Head*, [7] which has also been the locus of a great deal of work intended to produce various aspects of this capability under the framework of the Thinking Head project. [8]

Finally, I list the component sequences (i.e., the dynamic relations) of the process. What interaction needs is

- A potentially dynamic system in some environment.
- The entry of an interlocutor and a stimulus generated by that interlocutor.
- A response to that first stimulus, functioning itself as a first return stimulus.
- A further response to that first return stimulus followed by a further response on the part of the second party.

This must develop into an ongoing loop of stimulus-response sequences. Ideally it should follow a coherent line of development, and it might stimulate the production of new behavioural repertoire. Thus begins the process of developing a creative machine, in the way that we are creative.

ENGAGING DYNAMICS

FRANCES JOSEPH

This paper addresses some practical and theoretical issues arising from the development and implementation of a pilot programme of new works for an interactive screen environment sited within a performing arts complex. The notion of performance as embodied practice functioning both as a metaphor and an analytical tool activates a series of social, technological and cultural framings.

This paper addresses some practical and theoretical issues arising from the development and implementation of a pilot programme of new works for an interactive screen environment sited at The Edge Performing Arts Complex at the Aotea Centre in Auckland. The 'Digital Art Live' (DAL) programme is an initiative supported by The Edge in partnership with CoLab Creative Technologies Research Centre, which is based at Auckland University of Technology (AUT).

Struppek (2006) has written about the differences between public and individualised forms of screen display. She has suggested that the zones between virtual and physical public spaces could be used more constructively for 'the creation and exchange of culture and the formation of the public sphere through criticism and reflection.' [1] She recognises that new co-operative relationships are needed to enable new approaches and to challenge conventions. The collaboration between The Edge and CoLab is exploring some of the opportunities and requirements needed to support such cultural exchanges in Auckland, New Zealand.

The location of DAL in the Owens's Foyer of The Aotea Centre outside the ASB Theatre is distinct from urban screens in public squares, from interactive art in gallery spaces and from interactive games that are increasingly found in educational and domestic environments. The environment of The Edge as one of New Zealand's leading performing arts, entertainment and convention facilities, engages many different communities and introduces some particular considerations and opportunities. The notion of performance as meaningful, embodied practice that functions both as a metaphor and an analytical tool, activates a series of distinctive social, technological and cultural framings that the DAL pilot programme has set out to explore and analyse.

Earlier in 2010 The Edge council reallocated some funds earmarked for buying more traditional artworks like painting and sculpture for the theatre foyer for the purchase of interactive screen technology. At a meeting between CoLab and The Edge in mid 2010 the potential of both organisations working together to establish a flexible technology platform and a sustainable exhibition programme of interactive works was recognised. While The Edge management had already made decisions as to the type and configuration of the screen, there were several critical issues that required further consideration. Firstly, the curation of a programme that would not only present new interactive art works, but might relate thematically or formally to the Edge's ongoing performing arts programme including city wide cultural events, such as festivals. Secondly, the development of a content management platform that could support a range of different software and approaches taken by artists. Thirdly, while The Edge was keen to support the development of an ongoing programme, it needed to identify what was required to do this. It was decided to run a year long pilot programme, supported by The Edge, CoLab and AUT, to research, develop, test and evaluate strategies for engagement, content generation, funding and programme organisation of the interactive screen environment. With the screen scheduled for set up in the foyer in

December 2010, an initial test programme to open in February 2011 as part of Auckland Festival was proposed. A more formal programme would be launched in April.

The Digital Art Live interactive screen consists of 12 x 46 inch Samsung thin flat screens organized into a large composite screen. Each screen panel measures 1025mm x 579mm including the bezel. The overall size of the wall is 4100mm x 1737mm. It's a 12 screen display layout, being 4 screens wide by 3 screens high. Each screen has a 16:9 ratio, but the overall ratio of the entire screen is 21.3 x 9, or 2.37 (cinemascope is 2.35 so it is close to this scale). Each screen has a native resolution of 1366 x 768. However the screens can support a splitting system by stretching the image across the entire wall. This means that the overall resolution of the screen is 1366 x 768 pixels. The initial set up included a Logitech HD webcam C510 positioned below the screen. It was agreed that additional sensor and input devices or camera configurations could be considered for incorporation into the system. Subsequently a ceiling mounted camera has been added. While the multiple screen set up presents certain challenges for artists, it has other advantages including the clarity and definition of image, and the opportunity to produce single or multiple screen works. The grid format of the screens echoes the grid in the history of painting.

Inquiries made by CoLab identified iion, an Auckland based company involved in designing an interactive management system. 'Media HD,' which had been developed for the advertising industry. It supports presentation across a wide range of file formats and interactive modes, to provide programme options to ensure continuous delivery and viewer analytics. A basic platform would be provided and additional functionality to support different software and hardware inputs would be added as required, supporting the programme roll out. Processes were put in place to appoint a part-time interactive programme curator. In the meantime, the DAL management group, made up of representatives from CoLab and The Edge, began the programme development.

Three emerging artists were identified and invited to exhibit between mid February and mid March 2011 in a program me titled 'Screenplay at the Edge' as part of the Auckland Fringe Festival. The programme included: 'The Ruru' by Naomi Lamb and The Wanderer Productions; 'Speaking Trees' by Anselm Bradford and 'Magic Garden' by Robert Carter. These three works used very different interactive strategies and presented diverse challenges related in part to the short timeframe, the different levels of experience of the artists in exhibiting interactive content and to the set-up and testing of the Media HD platform. For example one work used a text interface on an iPad. This limited interaction as audience members first read from the iPad rather than experimenting directly with the work. While each work had its own integrity, collectively they did not work as a coherent programme. The Media HD platform functioned well in supporting a range of software applications and hardware devices and the automatic, sequential display of each work (programmed to show for one hour at a time) while also allowing the audience to manually select from the programme. However the Screenplay event presented a number of problems, notably some confusion for the audience in understanding the three different interfaces and interactive strategies of these works. While printed information was provided, it was realised that a simpler strategy, presenting a single work/type of interface in an exhibition would be more effective. It was also recognised that the particular space and configuration of The Edge system would inevitably require some adaptation by iion to support the presentation of new works, particularly if they used software that needed to be added to the system. However a distinction needed to be made between this necessary level of technical adaptation/system development and a more fundamental need to support artists working in other media forms in developing greater understanding and experience working with interactive media. CoLab was in the process of setting up an interactive media suite for teaching and research at AUT. The Media HD system was installed as part of the suite for artists, students and researchers to access for workshops, experimentation and testing of new interactive work.

In April 'Chirp' an original interactive work by Wellington based artist Stewart Foster, was presented at the formal launch the interactive wall. Stewart's work explores real time interactive environments infused with bodily sensations and computer technologies. These hybrid spatial environments explore the limits and interface between physical and digital space: 'We are entering a new realm of digital connectivity where our bodies are extended into digital networked space. The ubiquity of mobile internet connecting devices, electronic displays and social networking spheres all contribute to the rupture from the corporeal body into a constructed digital self.' [2] The work used camera vision and live feeds from twitter. Tweets that included the word 'happy' were automatically harvested and displayed. Motion tracking traced the outline and movement of people moving in the foyer space, plotting a series of blue circular shapes across the screen. The representation of participants in the work was important in that it gave them insight into one of the works interactive strategies. The conceptual impetus of this work and its aesthetic demonstrated Stewart's long-term involvement with interactive media and prior experience in developing large-scale public interactive digital art.

In May curator Nolwenn Hugain-Lacire was appointed to direct the DAL project as a one-year pilot programme. Confirmation of the next two exhibits was set in place, with exhibitions confirmed by Auckland artists Kim Newall and Clinton Watkins. The Edge agreed to an artist's fee for each exhibitor, a policy that the DAL committee saw as fundamental to the longer-term sustainability of the programme. A curatorial strategy was formalised, which included a public call for artist's proposals as well as a summer season of work by students and workshop participants. Supporting the call for proposals, a technical manual for artists was published. The call for proposals invited artists to create work that supported engagement with a public audience through technological experience. It identified a special interest in work that responds to gestural input, supporting performative interaction between the user, the physical space and the onscreen content. It also encouraged works that involve text input, audio, real time or social networking technologies from artists or collectives producing professional creative works. [3]

Planning has also been initiated for a series of workshops to be conducted at the CoLab Interactive Suite in 2011 and over the summer break. It was recognised that emerging artists and those working in other media that they might wish to extended into interactive formats, would be more effectively supported through a workshop programme. The DAL pilot programme will present innovative creative works that were conceptually and technically resolved in order to establish and promote support for a long-term programme. Experimentation and capability development, supported through the CoLab workshop programme is crucial to developing a broader community of practice. A process outline was developed to ensure dialogue between the artist, curator and iion, to be followed by a series of tests of works-in-progress at the Interaction Suite to trouble-shoot any issues ahead of the opening date.

The DAL pilot project is a work-in-progress. Organisationally we are learning through this process. Documentation will soon be available in an online archive on Cola's website. While it is too early to provide a fuller analysis and evaluation of the programme some insights have been gained to date. These include the increasing levels of positive audience feedback and audience response, the formalisation of support provided by The Edge for artists fees and recently from Creative New Zealand for funding to commission new interactive work as part of the DAL programme.

We are currently exploring a number of different strategies including corporate and institutional sponsorship, as well as international cultural programmes to contribute to the ongoing support of the programme. There is potential to commission interactive works for specific cultural events like the New Zealand Readers and Writer's Festival or the Pacifica Festival, which are closely linked to The Edge's ongoing programme. These events present opportunities for the exploration of different performative

modes (for example poetry or dance) and for extending beyond the spatial and conceptual limitations of a 2 dimensional screen into multi-dimensional cultural forms and spaces. The potential for ongoing research into interactive forms, interfaces, curatorial strategies and cultural enterprise, supported through academic funding, is another area that can contribute to the outcomes and value of this initiative. In a small country like New Zealand, a multifaceted approach that builds on institutional collaboration and local networks is essential.

RELEASING THE GHOST : RELOCATING AN ONLINE EXPERIENCE INTO THE CORPORAL WORLD

Nedine Kachornnamsong

The article is a part of an ongoing research project aimed to transfer and recreate an experience found in online interaction into a spatial setting. By applying the concept of technology appropriation, together with the idea of the ghost in the machine, Yes / No / Maybe (2009) is an interactive art event, a social experimentation, which transferred an online dating experience into the physical world.

After the Essence

Personal computers, mobile phones and closed-circuit television, to name but a few digital devices have become everyday objects. Unlike their mechanical predecessors which utilized motion and kinetic force, these machines excel, mainly, in computing and data processing. They aim not to aid, but to empower. While the older machines are big and clumsy, the ones of the new era are neat and dynamic. Completely encased, clean and static, their capacity is not limited to their functions, but incorporates as well, modes of cybernetic operation which are expansive and abstract.

In the world of digital omnipresence, electronic signals are sent, retrieved and consummated. They respond at the speed of light; a vast network of machines lies invisibly. It is not the speed of the machine but the speed of change that painted the image of our future living with technology. From Mary Shelly's Frankenstein to the ongoing Star Trek fiction, these popular depictions are based on either utopian or dystopian view. This is an unapt dualistic approach, seeking to interpret the role of technology into good or bad by either ignoring the influence of technology or rejecting our responsibilities towards it. [1] Since our relationship with technology is mutual — we create technology and technology creates us — to engage in such binary classifications, one would need to be as naïve as to uphold the separation of humans and technology.

Enframed by the good and the bad, we see only the two sides of the same coin and not the object as a whole. Perhaps it was Heidegger who first called for a more holistic view of modern technology. He claimed that the only way to critically reclaim technology is to denounce its instrumental aspect and take a look into its essence. [6] As now, the coin is more or less recognized, I would like to further explore its comparative value at use; to reach beyond what technology could be, and instead consider it as a notable source of understanding. This is because technology is our portrait, it projects how we want to appreciate ourselves in the world.

My first attempt to apply forms of knowledge found in the use of technology was during the site-specific project 'In Place-spective' (2005-2006) in Copenhagen airport, Kastrup, Denmark. Similar to many other airports, it is a space of security, control and standard; a space to go through — always the start but never the destination. Its characteristics of in-between space and homogeneity make up for its lack of meaning and detachment. [4], [5] Even though, a number of theses on 'place', from fields as diverse as philosophy, geography and architecture, were applied to improve our experience at the airport, their solutions are still far from satisfying. After a week of 'quick and dirty' ethnographic research in the transit area, I found the attempt fascinating; trying to redefine a sense of place using influences from another perspective, to find something never been implemented by any airport operators.

I became interested in online communications, where a sense of place exists without the need for physical space. Blogs, web-boards, chat rooms and fora are not only 'spaces' for people to socialize or hang out, they form a complete 'place' when community, attachment and belonging are created among their users. Unlike virtual reality, a cyberspace is primarily constructed through the use of metaphors, instead of the real world mimicry. Graphical User Interface (GUI) is a metaphorical application used to associate visual representation with literary meaning. It involves terms such as desktop, window, page and anchor in order to convey how the elements of the interface and system should be used and navigated, respectively. Another further extension of the metaphor is normally used as an implication, for example, to make understood the purpose and expected activities delivered through the internet portal. [7] This latter type of metaphor such as online market, internet forum, electronic library and (cyber) space, do not refer to physical representations but rather, higher level abstractions — concepts of online space. In other words, we need to establish our own "personal cosmologies" [8] by coupling online possibilities with activities that exist in the real world to be able to fathom the system's uses. [11] Hence, the sense of place we establish within online communications is another strategic ontology imported from the material world to act as a framework for our online interactions. [9] Evidently, without the help of online technology, it would not be possible for us to disassociate the concept of place from the spatial setting.

TECHNOLOGY APPROPRIATION

The difference between an introduction and an appropriation of technology is very well known within the implementation of cybernetic technology. Scientists, engineers and designers may suggest how the technology should work but people are the ones who choose how to use it. Despite the fact that a few people have foreseen the ubiquity of Short Message Service (SMS) or the success of social networking sites, to the virtual reality communities like Second Life, these unexpected receptions of new technology resulting from the meaningful process of 'making use'.

Consequently, the development of any technology depends on both the makers and the users. An example of people unconsciously making place out of virtual space is not simply a coincidence. It is a preference we express, a choice we make through the use of technology. This predisposition will, in turn, reshape the coming creation of technology. And since technology is governed by our determination, it would be unseemly to indicate that it is either unintended, or untrue [3] or reduce it to an accident. [10] And if we are to be more mindful in the fabrication of technology, it is crucial for us to recognize our responsibilities inherent in the role of users.

The Ghost in the Machine

The thought of recognizing ourselves in technology is intriguing especially when it comes to digital applications. These are the machines that have earned the title of being ‘smart’, crossing over between intelligence and physicality. In *A Cyborg Manifesto* (1991), Donna Haraway refers to the disappearing border between humanity and cybernetic machines, which “have made thoroughly ambiguous the difference between natural and artificial, mind and body, self-developing and externally designed, and many other distinctions that used to apply to organisms and machines. [2]” In other words, the cyborg problematizes the dualistic concepts that are commonly used to define humanity. Still, the rigid structures in most of societies leave us no alternative but to comply with this dualistic framework.

Even though, from the view of cyborg politics, it seems absurd to engage the division of ‘either and or’ as such, reflected by the *In Place-spective* project, I found that the ghost in the machine approach was invaluable for my thesis of technology appropriation. This is because for every machine, I believe, there is a ghost. And what we are haunted by is nothing but the ghost of our own desire. Only with our will can technology and machines move forward; technology without appropriation is nothing more than an already forgotten memory, which no longer paves our path to the future.

RELOCATING THE GHOST

The idea of integrating technology appropriation came into place in 2008 during a discussion with my then colleague Vadim Dubrov. We were exchanging our views of socialization when I mentioned the concept of a “traffic light” party I had come across a few years earlier. In this particular type of party, organized mostly among college students, the participants are required to dress in one of the traffic light colours which signify their level of dating preference — green is available, red is not available and yellow is undecided. I have never attended one of these parties as such, but I found it is amusing in terms of social interaction. Yet, it is not putting on different coloured clothing that provides traffic light’s attendees any new opportunity. Rather, it is through ‘making a statement’. Since yellow group participants have an ‘unknown’ status — the basic state held by any partygoer — the only group of people who benefit from this are those dressed in red, as they will be less disturbed by the green group which has a better chance with those at the party who are keen to have a date.

This prioritization of the declaration participants’ dating interests found in “traffic light” parties, is similar to online dating. By looking into the structures of dating websites and combining them with the “traffic light” concept, there seemed to be an opportunity to transform an online dating experience into a material setting. Since love and (romantic) relationship is one of the greatest convictions found in human history, this is a challenging opportunity to bring forth such desire — a possibility to bring the ghost back into the world.

FROM THE ONLINE TO THE OFFLINE

To transcribe this particular desire into an everyday setting is to deliver an online dating experience in an offline location. Thus, the different of people’s behaviours from the two settings is needed to be considered in combination with the concept of the traffic light party. There are principles of dating websites which are the keys to delivering the online dating experience that do not apply in the sphere of face-to-

face interaction. Firstly, in order to optimize the search process and increase pairing opportunities, participants need to be able to indicate their level of socializing preference (e.g. just looking, looking for friends, looking for dates, etc.). Secondly, while pursuing their interests, users must have the opportunity to either reveal their personal information or remain anonymous. This possibility for obscurity is what encourages people to become more open and active in their online social interactions. Thirdly, the playful element of online-dating sites represents an informal atmosphere that enhances the socializing opportunities where the users can feel more relaxed and casual.

Nevertheless, declaring a level of dating interest is successful in the online dating because cyberspace is designed for multitasking — one searches in parallel with many others. Thus, it is effective to provide users with an easy way to filter more than one interesting candidate out from the pool of online accounts. It is not only that multi-tasking is rather difficult to do in the real world, but also that such an approach is considered to be unpleasant according to conventional social norms. To succeed in transferring an online dating experience into the material world, the interactions between people have to be more dynamic. Therefore, an interactive installation was chosen as a tool to bring these two domains of interaction in to compliance.

In order to apply the above characteristics of online communication into a physical setting, this project consists of the setup of the event venue and the introduction of a new social environment.

- The venue: the setting and location where the project will take place needs to have a good atmosphere for socialization. A form of social gathering will be arranged and opened to public participation.
- The socialization strategy: the new social situation will be initiated by transferring elements from cyberspace interaction into the physical world. Therefore, the objective is to create an environment in which participants can recognize other people's level of socializing interest while their exact identity remains unknown.

An interactive system will be created as the means to simulate the informative environment that will roughly show participants the level of socializing interest in their surrounding area. Still, this indication shall only represent an average measurement to avoid a 1:1 relationship where the identity of participants and the type of socializing interest can be matched.

Yes/No/Maybe

It is crucial for a participatory project to begin with a period of pilot testing that emphasizes implementing the concepts rather than aiming for an inclusive outcome. While focusing on creating a platform for social experimentation based on the frameworks of internet dating, the main objective of Yes/No/Maybe was to produce knowledge — an analysis of the data collected on the participants' flow and movement — which could be used for further development.

This pilot project was realized during a joint residency program with Ljudmila and MoTa in Ljubljana, Slovenia as an interactive art event. In order to foster an atmosphere conducive for mingling and socialization, it took place in the café area of Moderna galerija, Ljubljana where there was music, DJs and a bar where drinks and refreshment were available for purchase. The registration process was divided into two steps in order to maintain participant anonymity. First, before entering the event, each participant had to specify his/her dating interest for the evening as a 'yes', 'no' or 'maybe' in a paper form. This was

then, folded and exchanged for an electronic tag containing microchips with a unique identification. Afterward, the pairing and registration of dating choices with the tags were carried on by project staff.

TECHNICAL SOLUTION

The technical part of this project was under the supervision of Luka Frelj from Ljudmila. Since it was a pilot project constrained by timeframe and budget, instead of mapping participants' movement using Wi-Fi or long range RDIF technology, a more practical solution was to use IR emitters and Wiimotes for the tracking input. Our ID tag design was inspired by Graffiti Research Lab's Throwies which are small, cheap and aim for temporary use. In each tag, two LR44 batteries powered two IR emitters and an Atmel ATtiny45 micro-controller which was programmed to flash a unique ID signal. Six Wiimotes were hung from the ceiling to cover the whole area and receive the signals sent from the IR emitters in a different time interval. Using the information from the Wiimote sensors, the computer software then mapped the movement of the tags (and the owners) into physical space by changing the LED lights which represented the average value of the socializing level (green, red or yellow) of individuals in that particular area.

THE RECEPTION

The public response to the project was more than we had expected. The event was originally planned to be of moderately sized, but turned into the evening's biggest event. After 40 minutes, all of the 75 ID tags we had prepared were given away. And since Moderna Galerija is a public institution, we could not impose a restriction to stop people from entering the event. At the highest point of the evening, the number of visitors reached an estimated 300 people. While I was astonished by the project's reception, at the same time I understood that it was unfortunate for my research. With only 25 percent of the participants actually connected to the system, the data was inadequate for the analysis. However, if there was any conclusion to be drawn from the event, it would be that the ghost (in the machine) is our desire and the thought of an unrestrained desire had drawn people together that night. In other words, we were all eager to release the ghost from the machine.

Acknowledgements

In addition to the participants of Yes/No/Maybe, I would like to acknowledge the following supporters and their contributions: Vadim Dubrov, Robertina Šebjanič, Luka Frelj (programming), Ida Hiršfenfelder, Matthew Rana, Thomas Collins, Sara Hallström, Sofie Norhstedt and Ingeborg Kofoed Brodersen. My further thanks also go to Ljudmila, MoTa and Moderna Galerija in Ljubljana, Slovenia.

DIALOGUES WITH DECAY: TRACING NARRATIVES OF DATA SPACE IN PAT O'NEILL'S "THE DECAY OF FICTION"

Kristy Kang

This paper outlines the formative dialogues that emerged during production of the experimental film *The Decay of Fiction* and its interactive counterpart *Tracing the Decay of Fiction: Encounters with a Film by Pat O'Neill*. The project was a collaboration between filmmaker Pat O'Neill and The Labyrinth Project—a research initiative on database documentary directed by media theorist Marsha Kinder at the University of Southern California.

Installation view of "Tracing the Decay of Fiction: Encounters with a Film by Pat O'Neill" by Pat O'Neill, Rosemary Comella, Kristy H.A. Kang and The Labyrinth Project, DVD-ROM, (Copyright 2002, photo by Kristy H.A. Kang).

In 1993 experimental filmmaker Pat O'Neill was introduced to the Hotel Ambassador. Built in 1921 in the center of Los Angeles' Wilshire corridor, the formerly grand hotel was a famous nightspot that hosted the Oscar award ceremonies and became a magnet for dignitaries and Hollywood luminaries in its heyday. Later made infamous as the site of Robert F. Kennedy's assassination in 1968, the Ambassador closed in 1989 and was left vacant, its abandoned spaces periodically leased as a location for movie shoots. Today the site is home to the Robert F. Kennedy Community Schools. O'Neill was given a tour of its spaces long after its doors were closed to the public and inspired by this urban ruin, he began filming, capturing the way light would move through its surfaces. This collection of shots (captured using a combination of computerized motion control and time-lapse photography) was edited with a temporary soundtrack from noir films and became the basis for O'Neill's 2002 film *The Decay of Fiction*. While working on the film in 1997, O'Neill was invited to collaborate with The Labyrinth Project (a research initiative on interactive narrative at The University of Southern California directed by media theorist Marsha Kinder) on a digital media project that would be based on his film. This collaboration resulted in an interactive DVD-ROM published in 2002 called *Tracing the Decay of Fiction: Encounters*

with a Film by Pat O'Neill. [1] This paper will outline the history of how the digital iteration emerged from O'Neill's film and explore the dialogues that developed while these two forms of *The Decay of Fiction* were being produced.

Since 1963 Pat O'Neill has been creating a body of experimental films that cannot be easily categorized as belonging to any singular strand of cinematic style. His work exhibits an intimate mastery of image processing techniques conventionally used to produce special effects in cinema, but the layered landscape of sound and moving images he composes extends beyond the limited language of traditional effects. [2] Rather than creating seamless optical illusions, O'Neill foregrounds the gaps between his densely layered imagery to orchestrate a different kind of illusion – one of unlimited associations in the mind. A poetics of associative meaning is awakened when watching O'Neill's films and it is this matrix of imagined trajectories that corresponds to one of the characteristics shared in film and digital media discourse – non-linear narrative.

During a workshop hosted by The Labyrinth Project at USC's Annenberg Center for Communication in 1998, media scholars and artists were invited to discuss the possibilities and challenges in creating an interactive non-linear narrative based on *The Decay of Fiction*. O'Neill (who had no prior experience working in digital media) was invited by Marsha Kinder to collaborate on this project because their close friendship created a foundation of mutual respect and trust from which one of the first Labyrinth Projects emerged. Moreover, Kinder had written about O'Neill's work in the 1970s and wanted to collaborate with someone whom she admired and whose work had great potential for interactive database narrative. The goal of the collaboration was to make an interactive work that would be emotionally engaging while both experimenting with and retaining the pleasures of cinematic narrative. Kinder defines narrative "not just as the idea of the well-made story with a three-act structure but...as a cognitive way for contextualizing the meaning of perceptions. It's a combination of data that's selected from a bunch of different databases and put together in interesting ways. And I think Pat's film have that kind of structure." [3] In the computer world this modular architecture of non-linear narrative typically takes shape in the form of a database.

In his book *The Language of New Media*, media theorist Lev Manovich traces the origins of the database to computer science and defines it as "a structured collection of data. The data stored in a database is organized for fast search and retrieval by a computer and therefore, it is anything but a simple collection of items." [4] This idea of data as a "collection of items" corresponds to the way in which O'Neill collects material for his films, identifying himself as "a kind of scavenger that looks through a lot of existing material and finds items that spatially or in terms of feeling have connections to the basic piece." [5] The modes of selection made by the computer or by O'Neill, can be considered non-linear in that items are chosen randomly from a constellation of possibilities. The difference, however, is that computer data exhibits no intrinsic value or associative meaning. The machine does not choose, judge or make cognitive connections between items but reduces them all to identical, sterile bits of information. Although the database evokes a very contemporary notion of computerized consciousness, it connotes a lack of corporeal presence and an absence of the kinds of sensual pleasures found in O'Neill's narratives. Rather than a database that fetishizes computer consciousness, I would like to imagine an embodied *data space* – one that is grounded in human consciousness mapped onto spatial trajectories.

The orchestration of space is central to the narrative trajectory presented in *The Decay of Fiction*. Space takes precedence over action, as opposed to action forming the underlying architecture in most traditional storytelling. The 73-minute film traces a pathway through the decrepit hotel, dripping with the

kind of nostalgic traces that abandoned spaces evoke, a pathway that O'Neill describes as a "choreography for the camera." [6] This feeling of nostalgia is heightened by the superimposition of noir film soundtracks onto the contemporary ruins of the hotel spaces evoking what O'Neill calls "the decay of storytelling or how storytelling merges with the environment or with a space that's foreign to it but somehow attracts it". [7] It is as though these stories are written onto the body of the hotel and watching O'Neill's scenes of sped-up-time, we are witnesses to this decay of fiction.

Conceiving the network of noir inspired action that would take place in the environment occurred after the empty spaces had already been captured on film. Having recorded the camera moves using a customized motion control system, O'Neill was able to later shoot his actors while repeating the same camera movement. Then through the process of optical printing, the foreground action and background spaces would be combined to form a composite image in which black and white figures inhabit a contemporary landscape shot in color. By compositing the present with the collective memories of a vintage era of Hollywood's past the Ambassador's remains become a repository of cultural history and imagined interactions represented in the film by a layer of ghostly fictional characters playing out noir inspired narratives. These narratives are periodically interrupted by animated interludes that seem to emerge from a parallel dimension formed from a repository of surrealistic moments. These parallel spaces converge as the film culminates in a carnival parade of performers whose dance of overlapping bodies blurs the boundaries between past and present. On one level, the film is an imprint of the hotel as artifact – a fossil of the past housing not only the imagined fictions invented by O'Neill but the public and private histories of Los Angeles' memory.

In the DVD-ROM, the hotel's history is an additional dimension that is only hinted upon in the film. In the film, as the camera pans across the hotel's ballroom we are reminded of the Robert Kennedy assassination as we hear excerpts from the speech he gave shortly before his death. Though this is one of the few moments in the film where historical memory materializes, it maintains a peripheral distance to documentary that haunts the edges of the screen. In the DVD-ROM, as the viewer navigates through the ballroom, additional material about the assassination is made accessible through a click of the mouse. This documentary material includes news clippings, archival footage surrounding the shooting, radio broadcasts of conspiracy theories and contemporary interviews with historians and witnesses offering their insights on this historical trauma. These documents are embedded within the surfaces of the navigable space where they remain hidden unless activated. The film de-emphasizes the "artifactual" dimension of the Ambassador hotel as a repository of history and although O'Neill initially struggled to incorporate his historical research of the space into the film script he abandoned his efforts, realizing that he "wasn't doing a documentary but a choreographed camera move with action." [8] Collaborating on the interactive iteration of *The Decay of Fiction* opened up the possibility to include not only historical material O'Neill had intended to include in his film, but additional material researched by Kinder, myself and others during the four year period in which the DVD-ROM and film were being produced. These included moving image archives of social events and publicity stunts hosted at the Ambassador, photographs of the hotel and its surrounding neighborhood from 1920 to 2002 and contemporary audio interviews providing different and sometimes conflicting perspectives on the history of the area. All these alternate layers of narrative possibility exist on the fringes of O'Neill's fictional spaces and can be accessed at any time. While exploring the hotel in the DVD-ROM, one encounters a diversity of data spaces and it is up to the viewer to choose which allegorical vector to follow.

Tracing the Decay of Fiction expands upon the uncanny qualities of place and memory that are present in the linear film by transforming the film's linear spatial trajectory to non-linear spatial navigation or "navigable space" – what Manovich identifies (along with database) as "another key form of new

media.” Although Manovich refers to 3-D computer generated virtual space as a model to illustrate the exploration of navigable space, the same description could be applied to illustrate spatial exploration in *Tracing the Decay of Fiction*. In the hotel, the viewer can activate any of its static interior spaces by placing the cursor over the edges of the screen, animating the still image into motion and following the camera moves that give the illusion of spatial navigation. Near the end of production on the DVD-ROM, Rosemary Comella invited Manovich to view the navigation system she had designed and programmed for the interface allowing the viewer to move within and between the hotel spaces. Manovich discussed his conception of “navigable space” but admitted he had never seen it realized in this particular way.

Another attribute that differentiates the DVD-ROM from the film is its use of “the image as interface.” Manovich states that “The new role of an image as image-interface competes with its older role as representation....a computer image is situated between two opposing poles – an illusionistic window into a fictional universe and a tool for computer control.” [9] The role of the image as both “window” and “tool” is illustrated in the DVD-ROM when the viewer pauses on a still while following a camera move through the hotel. Doorways, walls and windows become links to historical and fictional interludes. However, I hesitate to assert that the use of image as representation and interface are in opposition here. Rather, the immersive beauty of O’Neill’s cinematography is foregrounded and the navigational devices are intentionally integrated to minimally distract the viewer. Furthermore, in the work of experimental filmmakers like O’Neill the image does not always function as “illusionistic window.” Rather, the illusory quality of the image is frequently challenged using the very techniques used to maximize illusion in the special effects industry. While discussing the industrial apparatus that O’Neill re-uses to develop his own aesthetic, he states, “the by-products of the processes of special-effects work....that which undermines the illusion. That seems to be a very powerful thing – the illusion and the denial of the illusion, both present at the same time.” [10] Similarly, the binary poles of image as illusion and instrument are not in competition with each other in *Tracing the Decay of Fiction*, but are “present at the same time”.

Another nodal point of dialogue between the film and DVD-ROM is the differing role that montage plays in each. In the film, the viewer is introduced to O’Neill’s choreographed sequence of narrative spaces – the viewer sees an authored mix and a pathway arranged by its author. In *Tracing*, the viewer *participates* in the mix and editing is replaced by navigation and choice. In the film, a sequence of moving images is arranged over *time* while in the DVD-ROM the moving images are spread out into *space*. The viewer’s choices in that space are arranged into a spatial montage. Spatial montage is made explicit on the DVD-ROM by allowing the viewer/performer to control the “choreography of camera movement” from a selection of rooms in the hotel. By moving the computer mouse over indicators on the edges of the screen the viewer can control specific camera moves or slide into adjacent spaces. Alternately, one can choose a different space by using the original blueprints of the Ambassador’s architect Myron Hunt as a map to locate the spaces to explore on the DVD-ROM. While navigating the camera moves, the ghost-like characters that inhabit these spaces can be activated over the moving image with a click of the mouse. During the production of the DVD-ROM, there was a debate about whether to include the noir characters or to leave the navigable spaces uninhabited in order to retain the uncanny quality of the hotel and invite the viewer’s consciousness to inhabit its spaces. [11] It was a question of how closely the DVD-ROM sequences should mirror the film. While describing the period when he was first filming the Ambassador, O’Neill said, “as you walk around an empty building – especially when you know about who inhabited it and what happened there – you always expect you’re going to run into these people as you go around a corner. I mean its haunted in your own mind...so it was this quality that I was trying to figure out how to synthesize.” [12] While this haunted quality is made explicit in the film’s layering of ghost-like characters, in the DVD-ROM the viewer *can select either option* – either she can explore the empty space or inhabit it with characters from O’Neill’s fiction. Periodically, however, the

choice of combining foreground action and background space is automatically generated whenever an “earthquake” occurs. At these moments, the viewer loses control of the interface and a random collage is generated from the database of foreground and background elements. By alternating the layer of characters off and on or by viewing a randomly generated mix of multiple layers, the emptiness of the hotel takes on a heightened quality of mystery as you realize in your mind, that there is another hidden narrative frequency that haunts these spaces.

In summary, I have outlined the formative dialogues that emerged during the production of *The Decay of Fiction* and its digital hybrid *Tracing the Decay of Fiction*. First I explore the role of non-linear narrative in both projects and show how the complex network of associations created in O’Neill’s films correspond conceptually to the way non-linear narrative is structured in new media. This structuring takes the form of a database, a collection of items, or an index. The indexical nature of O’Neill’s process is reflected in his view that his films are like a journal, a synthesis of disparate units, “a collection of entries all by the same person but at different times and places.” [13] I propose extending the notion of the database to a data space in order to address the role of spatial navigation and spatial montage. Spatial navigation as a mode of organizing narrative footprints resonates in O’Neill’s observation that his films serve as “a record of an individual who wanders the land and from time to time stops to comment on it.” [14] I also explore the dual nature of image both as interface and mode of representation both in the film and DVD-ROM. All of these dialogues converge in the ruins of the Ambassador and in the end the hotel becomes a metaphor for the exploration of data, narrative, memory and history. Finally, it is a tracing of decay that is embodied in the haunted orchestration of spaces written on celluloid and encoded in digital space.

THE UMBRAGE PROJECT

Heather Kaplow

Umbrage responds to US media focus on cyberbullying. It is a creative application of frustration-aggression theory to interfaces intended as intermediary steps to live customer service in commercial interactions. The hypothesis is used to look at the recycling of aggression in the mundane activities of capitalist culture and at what individual experiences of frustration might say about where feeling lies within human-machine relationships.

Frustration is one of a small collection of emotional states that is as easily accessible in interaction with technology as it is in interaction with humans.

I am presenting work-in-progress audio and video documentation of several artistic experiments, collectively called "Umbrage", that are being produced and exhibited at various locations in Boston, Massachusetts (USA) between January 14 2011 and January 14, 2012. Each experiment-piece deals in a different way with the experience of frustration in the context of human-machine interaction.

"Umbrage" was conceived by four Massachusetts-based artist-curators (Jed David, The Novotny Collective, Jane Shapiro, and myself) in subtle response to the American media's focus on cyberbullying after a teenager from our region committed suicide on January 14, 2010. [1] Its aim is creative, critical exploration of frustration-aggression theory (Dollard, et al) focusing in particular on the type of digital interfaces that are intended as an intermediary step to live customer service in commercial interactions. [2] The frustration-aggression hypothesis' main principal – that personal experiences of frustration are the direct cause of the kind of targeted aggressive behavior known as scapegoating – is creatively tested and observed within obviously constructed, but still familiar contexts. These works were commissioned out of a desire to talk about the displacement of collective frustration and the recycling of aggression in the mundane activities of capitalist culture, but have begun, halfway through their duration, to offer interesting commentary on what the individual experience of frustration might teach us about human-machine relationships, and where feeling lies within them.

Of particular interest in each of the pieces that I will highlight here are expressions of the tension between dependency on technology and feeling threatened by it. A fundamental manifestation of this tension occurs in circumstances where a computerized interface must be used in order for one to be acknowledged, but must be transcended in order for one to be understood. That such a profoundly human liminal state – being caught between being acknowledged and feeling understood – can be drawn into such sharp focus in automated commercial interactions is at the core of what "Umbrage" addresses, and (I propose,) might be at the 'heart' or 'root' of an improved bond between humans and the technological interfaces that they interact with most commonly.

In the works we are presenting through "Umbrage", each moment of the time between the sensation of acknowledgement and that of feeling understood is broken down and examined as a potential stumbling block on the path to deeper machine-human connection. Each step of the process of automated acknowledgement brings the definition of acknowledgement into question and either lessens the likelihood of being understood by a machine or lessens the likelihood of being understood by another

paper that you are reading now went on for several more pages, continuing with the simulated technical difficulty until it hit the ISEA paper submission character limit. [5]

This subterfuge was created to hide the fact that my presentation about “The Umbrage Project” on the ISEA 2011 panel “Emotion Studies in a Contemporary Art Debate” was not actually going to be a presentation at all, but a performance by the same title.

Here’s the truth. I’ll start at the real beginning:

When I was a child, I was an actress. Not a professional actress, but a local, semi-professional one. I loved it. I was in a number of plays – mostly musical theater productions, but also some dramatic ones, and a television pilot. I did voiceover work, and even one opera. Then, when I was eight, I was in one play that I can’t even remember the name of, and it was my last play: two weeks before the production was to open, the director came to my house and told my mother and I that I was being let go because my personal life was interfering too much with my professional life. Though at the time I could not even quite grasp what that meant, it was the end of a career that I had imagined would carry me well into adulthood. Though I have no idea what my trajectory would have been, I saw many of my friends and peers from that time make it into national television series and movies.

I was very serious about acting. My audition piece was a dramatic monologue (involving a dead cat) by the character Dagmar from the 1945 play “I Remember Mama.” [6] My competitors were usually auditioning with comic-book-like monologues from a Broadway hit at the time called “Annie.” [7] My greatest aspiration in those years was to play the part of deaf-blind activist and author Helen Keller in “The Miracle Worker” and in particular, I wanted to perform a tantrum that the blind-deaf-mute central character has while resisting efforts by her teacher to help her communicate with the outside world. [8] [9]

Most heartbreaking about the end of my acting career was this: the girl who replaced me in the show that I was removed from was noticed by a talent scout during that production and cast in a touring production of “The Miracle Worker.” I believe she went on to play a supporting role in the film production of the musical “Annie” as well... [10]

When I started doing performance art work as an adult, I didn’t see any connection between this work and my childhood acting. I was performing at first to aid visitors in interacting with installed works that I was creating, and then realized that this was also a good strategy for getting people to engage with video works rather than just absorbing them passively. Everything performative that I have been doing has been reactive and site- or context-specific. I did not think of making anything explicitly autobiographical until I got the call for works and papers for the panel at ISEA.

Here is how I responded to it:

“Subject: Emotion Studies in a contemporary art debate at ISEA 2011 in Istanbul

Dear Ms. Rauch,

I am an American performance artist who has been looking for many, many years for the perfect setting in which to throw an enormous, incoherent, uninhibited temper tantrum. I am wondering if doing so might make a perfect fifteen-minute position (one not likely to be taken by anyone else!) summary

within your panel discussion – to be followed, obviously, by discussion with other panelists. What I think I could add to such a discussion is a visceral emotional experience in a context that is designated as intellectual (often read as non-emotional) space – for contrast and simple emphasis.

Thanks for considering the notion...”

And here is how Barbara Rauch, the panel’s chair, responded to my proposal:

“Dear Heather,

Wow, this sounds like a great idea to shake the panel and the audience. I love the idea that people will be empathetic, annoyed etc. Of course we will have to see who else we get and when the right moment for this intervention would be.

I suggest I will be in touch by the end of the week to update you on the panel. Do you have a short bio and a brief statement that we could use? I will send you the format length and more details by the end of the day on Friday.”

This began a series of exchanges between Ms. Rauch and myself about how to do the piece without giving away what I was doing while meeting ISEA’s requirements for bios and abstracts etc. Though I believe that the original tantrum that inspired my proposal raises profound questions about technology and addresses issues of mediation in an oblique way, since the performance was to be surprise, I developed a fictional set of ideas that could tie my behavior at the panel to technology more overtly, without being untrue to the themes of the tantrum in the play and its significance in my life.

Here was my description of the connection between the performance and the fiction in a grant application that I submitted in an effort to get support for the development of the piece and travel to Istanbul:

“I am seeking assistance in support of the development of a performance consisting of a fifteen-minute, double-time (in terms of speed) and double-length (in terms of time) solo re-enactment of a scene from William Gibson’s mid-20th century play “The Miracle Worker”. The famous scene, known as ‘the breakfast scene’, is the beginning stage of a process of breaking down the blind-deaf-mute central character’s disconnection from the world around her via the ‘technology’ of sign language. This scene was chosen, and is being altered or ‘remixed’ for the ISEA technology and emotion panel as a visceral means of demonstrating the tension between wanting to connect and the fear of connection – a tension always echoed in our reactions to frustrating interactions with technology. Because the main character in Gibson’s play is an isolated teenage girl, the piece is also meant to stand in symbolically as a venting of the frustration that bullied Massachusetts teenager Phoebe Prince – a victim of perpetual peer-harassment since immigrating to the US a year before – committed suicide over rather than express to those who might have protected her.”

As the idea evolved, I moved away from trying to mimic the exact gestures from the fight scene in “The Miracle Worker” and began watching children’s tantrums as well as autistic ‘meltdowns’ on YouTube. I worked with vocal and performance coaches in an effort to approximate a tantrum like those on YouTube, without doing harm to my body or vocal cords, in a manner that was somehow more adult than infantile. [11] After months of practice, I came up with something partially improvised and partially

structured, but it took a full fifteen minutes of buildup to get to the peak moments. Here are some of my progress notes from this point in the piece's development:

"Was planning on doing warm up exercises and then trying to choreograph or stage intro possibilities, but instead things devolved pretty quickly into something that could definitely qualify as a genuine tantrum. It was not loud or stormy – feeling too conscious of upsetting the neighbors upstairs so I didn't want to stomp and holler. Instead, it became a kind of sweaty, heavy breathing, rolling around on the ground, squealing, limb shaking kind of thing. There were even a few tears. I don't know what it looked like, but it felt like an adult (rather than a childish) version of tantruming – slower, quieter, but without any kind of reasonableness. Very sad-feeling, but also – maybe because of all of the breathing – very calming or releasing. I'm making a very big effort to keep my face relaxed, but it is hard – muscles for breathing and emotions tense up the face. I don't know if I slipped into it so quickly because I've had an emotionally exhausting last day or so, or because I did something with my body. Didn't feel connected to Miracle Worker or project narrative in any way. Felt more connected to the sights and sounds of my day than to the past..."

And again on a different date:

"Was able to get to the emotional part again pretty quickly this time. Some movement around the room, some rolling on the floor in slow motion, and then I flopped down on my back (getting low and flopping back seems to help) and was easily able to lie there crying and mumbling a bit. But I didn't actually feel sad – just the physical part of sadness somehow. I was saying 'what is wrong with me?' out loud to myself in a way that felt both like part of a breakdown that someone might be trying to stop and like me saying to myself 'what is wrong with me that I would think I should be doing what I'm doing right now in a public venue full of intelligent people who are working and thinking hard about serious things?' Also, did think a little about Helen Keller and acting back then a bit this time. Trying to remember what I really wanted when I wanted to throw that tantrum... Starting to think about Barbara's question about intervention and working some things out with her in advance. I think it might be okay to agree to have her come over to me and try to help if people seem to be getting concerned. I'll just wave her away with 'no!' or 'leave me alone!' or whatever. Also, since I may have trouble keeping track of time, we might want a code for that. Maybe I can ask her to see if she can calm me down by offering me a glass of water when I'm getting close to the time limit or if she feels I need to end things more abruptly. Actually, accepting the water might be a nice natural route out of the situation as well."

Midway through plotting the choreography of the fifteen-minute piece, I heard that the timing of each slot on the panel was being reduced to under ten minutes. I was relieved at first, because less time flailing and fussing sounded easier, but in practice it was actually harder to get into things and gain momentum. I came up with some mechanisms but they did not feel natural and raised new questions.

"Last night when I was practicing, I could not find any logical way to move from the slides to the motion/emotion. Even with motion, I couldn't find any emotion. I couldn't/can't remember my motivations for wanting to do this, and I couldn't/can't find anything to get worked up about...I timed how long it took me to get from trying to launch the slides to a tantrum that felt like it couldn't go any further and it was about 22 minutes. I am likely to have less than 1/2 that amount of time. How do I speed up and/or force the process? I realize also that I will need to be talking at first. So I am working on that. In last night's version, I tried to talk about a first piece I was going to show and about other curators I was supposedly working with and realized I need to make up some fake names etc. I think (if I can feel) I can

break down by trying to talk without working slides, but not if I don't have any content for this prepared! ...I may need to watch tantrums again on line, and also to reread my earliest writing about this/Miracle Worker."

A few days before the paper deadline, I had another Skype call with Barbara, the panel's chair. It began with her decision that it was unethical for me to do this piece without informing the panelists completely (and the audience to a lesser degree) about exactly what I was doing. I explained why I thought this would make things much harder for me, and then she suggested that I don't do the performance at all (or maybe only do a sample snippet of it) but instead have a five to seven minute dialogue with her about the development of the idea and how she got nervous about it at the last minute. Her idea was that this discussion would inject emotion into the panel as much as a performance would without making people feel tricked or criticized in some way.

Here are my notes from after that conversation:

"I feel like crying. I just got off the Skype with Barbara, and it sounds now like she doesn't want me to perform. No, that's not it—she wants me to perform, but not to throw a tantrum. No, that's not it. She wants me to talk in dialogue with her about not performing, and maybe to demonstrate a little bit of what I would have done if I had performed. She is frightened of distressing the other panelists/breaking the panel's trust, and wanted to let them in on what I would be doing as well as to warn the audience. When I expressed my concern about how I was relying on the tension of their expectations of normalcy to create a breakdown in such a short amount of time, and explained how I was no longer planning on flailing/kicking/screaming but just to lose my emotional grip. I tried to talk her out of telling them, but her fear is losing the trust that needs to be built for a successful, open discussion.

I actually am crying! It feels like the disappointment of my childhood all over again. Like being asked to leave the play again right before opening night. Why am I going so far if I'm not going to be performing? I don't think I've ever spent so much time or energy or money on anything or taken as much risk in my life as I have in preparing for this and it was because I felt I was uncovering a path from my past which seemed like it could take me someplace far more interesting than I could have imagined it would back then. Now I have no idea what I am doing. But I do know I have to write a REAL paper for it by Saturday...

Between now and the last time I wrote, I came up with a little bit of a setup, a prop that made more sense than a slide clicker, a dynamic (trying and failing to speak from memory rather than using slides) for breakdown that felt more naturalistic, and names/some simple dialogue to get started with. Maybe I can still do some of it in reaction to the dialogue with Barbara. I think she doesn't want to take responsibility for my behavior, but maybe I can still do whatever I want as long as I am the scapegoat?"

FROM IMAGE TO IMAGO - FLORA'S & FAUNA'S ARRIVALS AND DEPARTURES

Katerina Karoussos

This paper analyses the conceptual media of late antiquity which have built the entire imaginative sphere of the time and seem to be profound and flexible enough to meet the recent imagery strategies. Antiquity images are comprised of elements that have been chosen for the sake of their significations, as data of mutation not necessarily characterized by their aesthetic values but rather as aggregate spaces which could serve telematic mechanisms.

From Image to Imago - Flora's & Fauna's arrivals and departures

Visual Tendencies

In *De pictura* (1435), Leon Battista Alberti famously initiated to consider the frame of the painting as an open window. Alberti's single-point perspective has been, for most of the twentieth century, the dominant form of the image. Imagery has been operated as a single image in a single frame. However as Joseph Masheck points out "Alberti's window shares a larger problem of the so-called postmodern culture that deserves to be faced; hence the failure of postmodernism to defend its claims to the culture of the past, resulting in its closure and containment as just another movement".(Masheck, 1991).

The most important thing concerning this failure is the interpretation of things and phenomena according to terms of length, width and high, using Cartesian coordinates with one vanishing point as view-point. Consequently, as the development of technology and science required a more extensive vision for interaction and immersion, the concept of image, as it has been established by Renaissance and Enlightenment, has been proved inadequate. Actually, from pre-historical period up to Renaissance there is a completely different approach of visual aspects and even though it was inherited and implemented during 16th to 20th centuries, it was subject to persecution, being regarded as inferior to Modernity's brand new ideas.

However, with this narrow, one perspective, vision it is very difficult to understand the words of Chloris, the Nymph and mythological figure who said, while her lips breathe spring roses:

'I was Chloris who I am now called Flora'.(Ovid, 8th c BC)

Chloris, as a mythological figure presents the uprising of spring thus the celebration of life against the death. Did Ovid wrote a tender poem while Chloris in her description said that she was raped by Zephyrus? She said:

'It was spring, I wandered; Zephyrus saw me, I left. He pursues, I run: he was stronger; and Boreas gave his brother full rights of rape by robbing Erechtheus' house of its prize. But he makes good the rape and I have no complains about my marriage'.(Ovid, 8th c BC)

In Botticelli's "Primavera" one can see the scary face of Chloris as Zephyrus trying to grab her. Even if he extent his arms in a polite way as if he wants to embrace her, his face and his chest assure that he will going to catch her up as she was his victim. From the other side the ghostlike figure of Chloris testifies the impending rape. So Ovid's poem said that a girl was raped and a house was robbed. Is this a manifestation of life? Is Chloris a symbol of revival and joy just because she is surrounding by flora? In the same view, is Duchamp's urinal also corresponding to a source of life because is called fountain? (fig.1) Accordingly, we can say that frescoes in Lascaux caves are a celebration of nature, since they depicting fauna and flora. The evidence suggests that there were not merely decorations but codes of communication with others, humans and spirits. Additionally, those who create Nazca geoglyphs in Peru they were thinking of just a decoration that is visible from the sky? Undoubtedly the purpose of these designs related to astronomy and cosmology but with a perspective which is different from our common spatiotemporal interpretations.

Aggregate space

Images – which includes fauna and flora and by fauna I include the human genre - comprised of elements that have been chosen for the sake of their significations, as codes of something not necessarily implied of their effect as works of art, or arrangements of forms and colors. They devised from different aspects than that which is termed aesthetic.

In his Treachery of Images, Rene Magritte was more accurate from Botticelli's Primavera. He said: "This is not a pipe". This is something absolutely true. It is not a pipe; it is an image of a pipe. It does not "satisfy emotionally" - when Magritte once was asked about this image, he replied that "of course it was not a pipe, just try to fill it with tobacco" (Spitz, 1994). Indeed, this pipe which is not a pipe has been traversed from its physical status to the sphere of a form or a figure. In a quick historical review one can meet the elements of an image as codes of signification.

As a matter of fact Hegel and Derrida referred to Natural Religious Consciousness thus the first stirrings of religiosity within the minds which saw Nature as God, or as a series of gods. There are today many religions which still insist upon a minimum reverence to certain animals and/or elements in their rites. He spoke about flower religion as a neutral state of unification. And this is what these images depict.

'The state, in which spirit sees itself outside, apprehends itself as its own proper object in a natural and immediate figure. The spirit loses itself and finds itself again in these external natural objects.' (Derrida, 1990)

From the standpoint of this concept all things known to us—men, plants, animals, planets—are unstable, and they differ by the magnitude of their fluxions. But the thing, changing continuously in time, sometimes very much, and quickly, as in the case of a living body for example, still remains one and the same. The body of a man in youth, and the body of a man in senility, these are one and the same, though we know that in the old body there is not one atom left that was in the young one.

The image of invisible in antiquity was succeeded throughout noetic rather than esthetic perceptions. The image space was an aggregate one, not following a systematic order; this of a coordinate system. The aggregate space that Panofsky points out is this stage that all elements (figures, landscapes, motifs, etc) are in juxtaposition as consecutive signs.

One can meet this kind of space in archaic reliefs such as the horsemen of Parthenon. In this frieze there are sixty riders arranged in ten ranks. Each rank is marked by a figure placed nearest the observer and not overlapped by another. It is important to mention that the original word translated in English as

“frieze” is “zoforos” meaning something that brings and/or carries life. Thus, it is about energy and flow. This of course refers to the entire image and not a piece of it. You cannot extract an object as a central issue because aggregate space requires an overall visual syntax, as a signifying composition on several levels. This is something similar to emergence as a spontaneous organization in which every element involving into it maintains its object orientation while it is a part of a unit.

Parthenon frieze was a very good field research for Aristotle who in his “Metaphysics” claimed that the whole is more than the sum of its parts. This concept formed the idea of Holism (from ὅλος holos, a Greek word meaning all, whole, entire, total) meaning that all the properties of a given system (physical, biological, chemical, social, economic, mental, linguistic, etc.) cannot be determined or explained by its component parts alone. Instead, the system as a whole determines in an important way how the parts behave.

In his book “Perspective as Symbolic Form” Panofsky said that:

'...the art of classical antiquity the objects were not merged in painterly fashion into spatial unity, but rather were affixed to each other in a kind of tectonic or plastic cluster ...space was still perceived not as something that could embrace and dissolve the opposition between bodies and nonbodies, but only as that which remains, so to speak between the bodies. Bodies and the gaps between them were only differentiations or modifications of a continuum of a higher order. The represented space remains an aggregate space; it never becomes that which modernity demands and realizes a systematic space.' (Panofsky 1997)

The idea of this space is similar to the concept of a “stage”; or better to both its concepts, thus both of noetic layers in phases and of the stage as an area of performing. It is what Panofsky called: the lateral staggering; thus the disposal of all elements and their energy in a single unity no matter their position in time and space. Dickson’s film with Sioux natives produced in Edison’s Black Maria Studio, shows an organic movement of objects grouped together to suggest a unity of a single body. The idea goes back to ancient Greek drama and the chorus. The Greek chorus (or chorea) is a group of performers which are acting in one piece. The group comprised of twelve or fifteen members in tragedies and twenty-four members in comedies. They operate as intermediates in unison, in specific key frames into the play that considered of high importance.

The very same structure was used in visual arts. An important example is the Polygnotan vases. (fig.2). Here we can see the horses in a real time staggering;

'... all the body of the horse is presented in a single image, the rear elevation is placed alongside the front elevation, just as when entire figures are staggered.' (Panofsky 1997).

And in this united stage objects and figures operate in the same exact matter. Having a better look at those horses and bringing back in mind the Parthenon Frieze, one can indicate a kind of time- sequence and a notion of motion which is embodied in them as there is an inner principle that animated them.

In his contemplation on the Laocoon, Goethe states:

'To seize well attention of the Laocoon, let us place ourselves before the groupe with our eyes shut, and the necessary distance; let us open and shut them alternately and we shall see all the marble in motion; we shall be afraid to find the groupe changed when we open our eyes again'. This flicker effect that Goethe suggests is actually the mechanism of all the above images. Even if an image is one instant frame or a multiple of frames, they both comprised a mutable unity.

But is this a time sequence animation? It is more about a trace or a path rather than a structure of linear time sequence. This is something that can be easily understood through the stereoscopic analysis of movement by Etienne – Jules Marey.

'Marey though it necessary to reconstruct movement by making its physical wrapping abstract, based on a combination of visual formulas that do not prepose figurability, but on the contrary condition it.' (Micheaud, 2004)

Furthermore one can meet the whole concept in Duchamp's "The Nude Descending a staircase" (1912). Duchamp choosed to depict the motion of his nude in a single frame in order to posed the idea that time can be frieze for the sake of an augmented image. Therefore if the stage is one and only –as the single horizontal line of Polygnotan vase- and the objects into it are all in one unfolded, there is no need of change or movement. In this energetic space the venture is that of the appearance and disappearance of scene's elements, just like the flicker effect of Goethe's description for Laoccon's statue; hence the effort to demonstrate its exclusion of physical appearance and its modification to an abstract form. So we can say that Flora who was once Chloris had traversed herself throughout her modification, rather than changed herself. What we see in the stage is her path, her trace and not her portrait. The path, which is many time unsuccessfully interpret as serial movement, reflects the three stages that Hegel and Derrida raise in order to construct a unification.

'The concept of religion fills itself up, determines itself in opposing itself to itself, then reconciles itself with itself; in three moments that fulfill the absolute spirit. In the first moment, absolute spirit finds its existence in religion, but in a religion whose concept yet remains empty indeterminate. The second moment is that of natural religion which the spirit looses itself and finds itself again in these external natural objects.' (Derrida, 1990)

Media Res

The flower is neither an object nor a subject, neither a not I not an I, among all these opposites, the essence of the flower appears in its disappearance as a neutral stage. This absolute time of modification is depicted in all the above images and it is similar to the archaic concept of "in media-res".

In media res or media in res means to be into the middle of things is a Latin phrase concerning a narrative technique in which the story begins most of the times in the mid-point in where there is the most critical point of the narrative. In the house of Dioscouri at Pompeii there were two significant frescoes that one can see them now at the National Museum in Naples. The first one depicts Laoccon and the second one portrays Media. (fig.3) .We know from the narratives that both characters were in a very bad position the very moment of their depiction. Laoccon is dying from the snake's bite and Media is going to kill her children after a second. Each image has capture a moment in media res in which all phenomena whose nature is suddenly to break out, disappear and appear again in another mental stage, presented as unified in an unconditional and unchanging duration. Media stands to the right of the composition, frozen forever rather too "posed" to be natural. Their condition reflects the theory of flower religion which is followed by that of sun religion. The latest concerns the stage in which "the sun does not set, or it sets immediatly", like Goethe's flicker effect. Hegel placed this procedure in natural religion in where the sun is not yet a subject. 'In order to become a subject in effect' he said that 'the sun must go down.' But Zarathustra, Laoccon, Media, Chloris and all the other elements that had been mentioned before, stand beyond the route that Derrida called: from orient to occident with its double meaning, that is they are in a media res stage in where orient and occident is included, birth and death, east and west, male and female and all other opposite doubles, with no reference in vector magnitude in their spatiotemporal circumstances. One can assign meaning to Chloris' words: 'I was Chloris who I am now called Flora' by replacing the concept of image with the concept of imago.

Conclusion

In biology, the imago is the last stage of development of an insect, after the last ecdysis of an incomplete metamorphosis, or after emergence from the pupa where the metamorphosis is complete. As this is the only stage during which the insect is sexually mature and, if it is a winged species, has functional wings. In conclusion, in a neutral time all elements in an image reached their pick, performing in a gestalt effect while their depiction is of their absence rather than that of their re-presentation. What is to be shown, is the traces of their appearance and disappearance throughout an organic process of their unified mutation.

RE-MAPPING THE CITY IN THE DIGITAL AGE

Eva Kekou

The way we live and feel about the city is beginning to be affected by its information layer. Locative and mobile media can be regarded as an interface between the digital domain and the physical city. I investigate through media art case-studies the questions: How do people deal with this relationship between digital technologies and the city? How are cultural identities expressed through these projects?

Introduction

The way we live and feel about the city is beginning to be profoundly affected by its information layer. Today's cities are no longer limited to the experience of physical spaces. Cities are now characterised as 'Cybercities', 'Sentient or Hybrid Cities'. The digitization of the city, with technologies embedded into its streets and buildings and carried by people, has appended an informational membrane, which hovers over the urban fabric" [1].

We are seeing a change to the city where understanding its new behaviours and its interfaces is becoming as important as understanding its physical geography. The city's connectivity and networks now comprise the interaction between its wireless infrastructure, mobile phones, social software and embedded systems. Locative and mobile media can be regarded as an interface between the evanescent digital domain and the physical city, sending data from real world experiences back into the digital domain.

New communication technology and space

Social life in the 21st century is increasingly lived in media cities. During the last thirty years, the evolution of technology has added a new layer to the urban environment, challenging classical theories of urbanism and adapting it to the current ideas of the media. We can regard the contemporary city as a media-architecture complex, which has resulted from the proliferation of spatialised media platforms. While this process has existed at least since the development of technological images (in the context of urban modernization in the mid-19th century), its full implications are only coming to the fore with the expansion of digital networks. The term 'media city' is "designed to foreground the role of media technologies in the dynamic production of contemporary urban space in Lefebvre's sense of binding affect and cognition to space" [2].

The way we experience cities is shaped by the immaterial city of word, image and myth. It is through these that we learn not only to perceive cities, but also how to live in them. Today we speak of cyberspace and cybercity, which is more than a single integrated and ubiquitous entity revolving around the Internet. New technologies have revolutionized the way we communicate, interact, transport information and finally the ways in which we express ourselves. New technologies and new communication tools have the capacity to create new space for people to meet, interact and exchange ideas in what Habermas calls a "public sphere" [3]. Wireless communication technologies have also created new circumstances for 'locus' and 'time' and laid the groundwork for virtual time and place.

Urban life and society are related and narrated as artefacts, social problems, critical discourses in every era are reflected in society's artistic expressions. Such expressions reflect the way people live and are able to speak out, not only about themselves as individuals, but as a collective, through a number of public art and interactive media art projects. The new communication technologies have revolutionized the way people interact with each other and how information is transported. This is a result of a long process produced by innovation in telecommunication processes and other information technologies. The growing use of telecommunication systems is not only having far more influence on where people work and live, but is changing the character of activities that take place in the home, workplace and transportation. The diffusion of information technologies increases the complexity of cities by increasing both the number and type of interactions between individuals, firms, technical systems, and the external environment [4].

Most observers believe that technology will eliminate the need for cities as centres for interaction. The leading media guru, Negroponte has stated that the post-information age will remove the limitations of geography [5]. Digital living will reduce dependence on being in a specific place at a specific time, and the transmission of place itself will start to become possible [6]. While telecommunications technologies are certainly space-adjusting phenomena, the emergence of the internet, the growth of mobile telephony, and the diffusion of new information technologies are doing far more than rearranging the spatial pattern of activities in cities and metropolitan regions. New telecommunications systems redefine the fundamental elements of modern urban societies.

New technologies that are introduced every few months, reflect society's tendency towards globalisation. Services like Google Earth, Geographical Positioning Systems (GPS) and user friendly internet based Geographical Information Systems are widely used, making the most out of the wireless and mobile networks that exist in the cities. These are all ways of recording and imprinting our perception of space. The word geography has Greek roots. It comes from *gaia*: earth and *grafo*: write. These meanings have changed, together with our definition of geography. The term 'mapping' has changed with the notion of geography and the advances of technology. The geographical expression is entwined with its digitalized character.

Architecture and mapping are not only what is built. They are made of different aspects: material and immaterial. Architect Benedikt [7] saw cyberspace as the realization of ancient dreams of overcoming the impediments of matter. The design of cyberspace is the design of another life-world, a parallel universe, offering the intoxicating prospect of fulfilling - within a technology very recently achieved - a dream thousands of years old: the dream of transcending the physical world [8]. Novak shared a similar dream, arguing that the source of fascination with cyberspace is the promise of control over the world by the power of the will. In other words, it is the "ancient dream of magic, which finally nears awakening into some kind of reality" [9]. For Novak the sublime magic of cyberspace was characterized not so much by a loss of the body, but by an embodiment of the mind. But the body would be transfigured; not only without organs, but seemingly without limits. The rise of cybernetics coincided with a fundamental shift in urban thinking.

As Kittler points out, "the invisible city, with which Mumford concludes his world history as the history of the city, consists of more than mere information technologies operating seamlessly and at the speed of the light" [10]. New technologies, the hybrid conditions between virtual and physical, and electronics embedded into physical environments have also been considered as "non-material elements of architecture" [11]. The debate now is about how architects should respond and design within the contemporary

world, where space is constituted equally by conventional, material means, wireless networks and gadgets of new-technology. Taking further the notion of compression of space and time as introduced by Harvey, we speak of compression of work capabilities by the notion of cloud computing, which allows access to one's work from multiple geographical locations [12].

Aims and objectives

For the purposes of this paper, I have chosen projects to highlight digital mapping as developed through new communication technologies.

1. Athens by Sound

In order to highlight the idea of mapping the city in a multi-media digital era, I will use the project Athens by Sound [13], which was the National Participation of Greece in the 2008 Venice Biennale of Architecture. The project focused on mapping the city of Athens through the sounds everyday life created within it. The sounds we hear – but hardly ever listen to – can present the world around us as clearly as our vision. That is how people with visual disabilities understand and navigate normally in the city. We are just used to regarding vision as the dominant sense. The team of Greek architects responsible for the *Athens by Sound* project tried to focus on the aural impressions the city leaves on the visitor, by recording its sounds and presenting them to the visitors of the Greek Pavilion. They designed the dimly-lit space of the pavilion like a forest of hanging headphones, which transmitted the sounds of Athens. As the visitor walked amongst them, he could put on whichever headphone he liked, without knowing in advance what he might hear. What he actually heard was a sonic fragment of the city, revealing aspects of its identity and atmosphere. The whole space of the installation in the pavilion was treated like an interactive sonic map of Athens; a map that allowed visitors to explore qualities and fragments of the city step-by-step, instead of offering the usual all-encompassing overview offered by the traditional way of mapping. The map attempted to capture the sense of the unexpected and the surprising of the actual city and incorporate it in the installation as part of the navigation process.

How do people deal with this emerging relationship between digital technologies and the city?

Omonia square, a focal point of the physical formation of Athens, was placed in the centre of a 10x10 grid, drawn up for the mapping process, that was stretched across the whole city until it touched upon its limits that were dictated by the natural environment (the sea and the hills that surround the city). It was a way of defining one hundred urban spots, whose geographical coordinates were then imported to a GPS system and assigned spatial and temporal coordinates, from east to west. The spatial distances were one and a half kilometres between the spots and were transcribed to one and a half hours on a scale of time. Each horizontal line of the grid was scanned and recorded from east to west within one day. When these recordings were presented in the installation, the visitor was able to trace the city, following random routes. Fifty sounds were chosen for the headphones of the exhibition and other sounds were transcribed and written in words on the corresponding spot on the floor. The visitor was expected to read them on the ground and reproduce them mentally. As in the actual city, movements, events and the complexities of the human presence were elements that constituted significant spatial qualities within the built environment, abstractly represented as the labyrinth of cables and screens. These kinds of functions and movements are what ultimately constitutes urban space. In the attempt to negotiate the non-representable presences of the urban space in a map, the installation was forming an urban space, as Lefebvre would probably argue.

The space was designed to be interactive:, with the presence and movement of the visitor activating the sounds and images in the installation. The installation included also twenty-five scattered prisms with video-screens that were activated by human presence. When the visitor got close to one of the screens, it automatically turned on and played video and sound. The videos were shot and directed in a way that referred to regions of Athens through sound, without aiming at a visual representation of its distinct architectural or physical characteristics. The random activation of videos and sounds within the interactive environment of the pavilion space produced in turn multiple sonic qualities, intensities, layerings and densities, creating the identity of this unique space and its dynamic relationship with the people. The visitor, like the inhabitant of the city, was responsible for the sonic environment constituted by his own actions and trajectories within the installation space. "The sonic environment of Athens is ultimately the outcome of a certain urban culture, the carrier of which is the visitor himself, each one of us, out there" was stressed by the team [14].

The investigation of *Athens by Sound* attempted to deal with the broader issue of space beyond the material in various way: in reference to the sensuous and senses beyond the visual; in reference to new technologies as parts of our everyday urban environment and as representational tools that open up previously unforeseen possibilities for mapping; in reference to human interaction within a space; and in reference to the non-representable aspects of urban space. Within our own relationships with the sounds of the city we inhabit, we can focus on our immediate perceptions of our sonic environment; we can isolate ourselves in our own sound tracks through headphones; we can have the sonic experience of what is here and also of what is there. We can consciously turn down the intensity of the sound of the environment and focus on our own inner thoughts, or on something that is spatially displaced. The unique perspective of *Athens by Sound* presents the city as a fragmented constructed space, a hybrid of electronically mediated and real spaces.

2. Coffee deposits: topologies of chance

Coffee reading is an old art of fortune telling which takes on a new twist today with the ingenious use of digital technology, as it is expressed in Bastajian's "coffee deposits, topologies of chance" project, available for view on DVD [15]. The team created small mobile coffee reading places where people could visit and have their fortunes read off of a cup of coffee. Fortune telling, however, propagates various impressions among people, some of them quite negative, leading to an unofficial notion that it is either sinful or illicit. The locations of the mobile coffee reading places followed a predesignated route and used GPS coordinates so that they might be easily attended. The result of this project was a map of the coffee reading locations that can be detected by the network community and a digital documentation of coffee readings accompanied by the people's stories. "Currently Bastajian and Manavoglu are developing locative «post-scripts» via QR codes, geocaching and AR tacticts that expand the archive of Topologies of chance into public space" [16].

The old and superstitious art of fortune telling that evokes and is itself a sort of storytelling translates the space where it is performed into a mixture of emotional, ludic and topological locus. The presentation of the project through the use of an interactive DVD disk only enhances it as a documentary, proving that a combination of narrations can be viewed in various sequences for a different experience each time. In other ways a cinematic arises with interactions and new narrations according to the choices of the viewers. A game of uncovering secrets and documenting emotions that in the end ascertains the atmosphere of the space, "coffee deposits, topologies of chance" is a mapping method of human mentality in all its spectrum, employing traditional, mystical and esoteric practices which all imply a new type of cultural identity bound to traditional elements framed in a globalised digital culture [17].

3. Urban Digital Narratives [18]

This was a locative mobile artwork in street locations in central Athens created in the spring of 2011. The locative project was part of a workshop conducted by Rieser and Kekou in an inner city street where personal stories were constructed and developed by volunteers using *Empedia* [19] software to form trails triggered by GPS or QR codes. Video scenes or vignettes, based on documentary experiences of place and the communities in central Athens, were fleetingly revealed at different positions in the chosen streets by the scanning of QR codes. The video stories for display on mobile phones in the actual streets were created in a public engagement workshop in the city.

How are cultural identities expressed through these projects?

Digital Urban Narratives sought to address the powerless and the disempowered and attempted to map their stories, problems and trajectories onto the urban space of inner Athens using simple QR and GPS technologies, to give the widest readership for those with either smartphones or middle-range mobiles. The chosen area of Gazi-Keramikos was a very mixed inner city area, where gentrification had created a pleasure zone of clubs and cafes surrounded by established artisan communities and migrant communities to the North. These disparate elements faced multiple problems, above all a sense of powerlessness in the face of the ill-formed status for recent migrants and of displacement by rising property prices and rents in the south of the area, together with an influx of noisy and youthful revellers with hedonistic values into conservative working neighbourhoods. "After the Olympic games and given the absence of a program or plan to answer the pressing issues of a Mediterranean metropolis in transformation, the centre was almost abandoned to its fate. As a result, for many years, the city has resembled a ship tossed helplessly on stormy seas. As central Athens grew in the characteristic manner of a disordered Mediterranean city, the market forces privileged the creation of entertainment zones and we saw phenomena of arbitrary and ruthless commercialization by unrestrained private developers, instead of the creation of well-planned residential areas for the middle classes. The displacement of local inhabitants appeared as a clear trend, but in the long run it did not prove particularly advantageous for the upper middle class and their aspirations; instead, it created profits for short-term speculators and especially, the owners of nightspots and black economy enterprises" [20].

Multiple and complex narratives were recorded in audio-visual forms from all the disparate social groups. "Above all, immigration has played a determining role in the transformation of the city centre. Initially, internal migrants arrived looking for shelter and set up their coffee shops, groceries and associations. They gathered in and around Omonoia Square, met their kin and with other members of their social group to subsequently disperse around the city. After 1990, there are new arrivals. These are displaced urban nomads who had been moving around in emergency conditions. They start arriving from different locations. Due to its geography, the city of Athens was to become one of the main entrances of migrants directed towards Europe. Again we see the creation of gathering places, coffee shops and groceries, restaurants, Internet points and phone call centres. There is still no official reception policy for immigrants and asylum seekers. All they are faced with is a system of brutal arbitrariness" [20].

It is not surprising that Athens has become the focus of resistance to the imposition of draconian neo-liberal disciplines on its economy and that it remains the flashpoint for any future European economic crisis and the space where the contradictions of the market and its effects on the contemporary city appear in their acutest form. The uses of digital technology can highlight, augment and interpret these contradictions, giving voice to the dispossessed but their solution remains a political one. Urban digital

narrative has been an artistic project which was not meant to be but has been developed to be a political one, although artist ,curator and participants all got apolitically involved.

Conclusion

New media have the potential to express personal ideas and emotions about the city and map them onto the spaces that inspired them for further public consumption. They can simultaneously remap the city and give another dimension of understanding to it. New technologies can make users/participants both interact with the piece and express ideas in a collaborative, authorial role. The form of these interactions need not be formalised. They can be mapped in a loose and humorous way, which connects cities in a globalised frame and environment by a human critique which prioritizes the personal and the different over the detached and homogenising forces of globalization, hence reshaping our notions of citizenship.

DELAY AND NON-MATERIALITY IN TELECOMMUNICATION ART

RAIVO KELOMEES

My interest in delay concerns its ability to be part of the concept, when delay between sequences of creation, elements of time-based artwork, exposition and reaction or feedback becomes an integral part of the interaction with the artwork and inseparable from it.

Nothing Happens, 2006, Nurit Bar-Shai, internet project, <http://nuritbarshai.com/nh/nh.php>

1. INTRODUCTION

We can describe art as an asynchronous delivering of messages over physical or time distance. It maintains presence from the past and from far away, distant presence. Masters have been making artworks which are perceived by audience hundreds and thousands years later. It could be, that the sender of the artistic message has not been in existence for millennia (like authors of cave paintings). In this case, interaction between sender and recipient is not possible, but still, the act of delivery exists as there is a receiver.

We could create an imaginary axis of reception divisions, based on delay, where there are works of art on one side, whose 'transmission' to the receiver has lasted for millennia; and artworks sent and received in real time on the other side. Although this kind of formulation points to the vocabulary of information theory and though this viewpoint has been considered, art in this presentation has not been dealt with in this way.

Delays between performative acts and non-materiality in participative works are substantial attributes in new media art, but there are many examples in earlier art practice and art of the 20th century, which belong to the rich history of non-material art.

My interest in delay concerns its ability to be part of the concept, when delay between sequences of

creation, elements of time-based artwork, exposition and reaction or feedback becomes an integral part of the interaction with the artwork and inseparable from it. Naturally, we can distinguish other episodes of delay, like one which is happening between creative intention of the artist and creative execution of the artwork.

2. FROM PAINTING BY TELEPHONE TO INTERNET ART

László Moholy-Nagy's "Telephone Paintings" were made in 1922 and were almost the first examples of early telecommunication art. Evidently, as historians write, he got his ideas from „Dada-Almanac”, which was edited by Richard Huelsenbeck in Berlin in 1920. Huelsenbeck presented the provocative notion that images could be ordered by telephone. It inspired László Moholy-Nagy, who lived in Berlin. [1] László Moholy-Nagy wrote:

In 1922, I ordered by telephone 5 paintings in porcelain enamel from a sign factory. I had the factory's colour chart before me and I sketched my paintings on graph paper. At the other end of the telephone, the factory supervisor had the same kind of paper, divided into squares. He took down the dictated shapes in the correct position. (It was like playing chess by correspondence.) . Thus, these pictures did not have the virtue of the "individual touch," but my action was directed exactly against this overemphasis. I often hear criticism that because of this need of the individual touch, my pictures are "intellectual". [2]

We can say that in 1922 the first attempt was made to create and deliver a computer graphic picture over distance. The author was „removed“ from physical result of his work.

If we think more deeply about the process of creation of Moholy-Nagy, then there are different steps, activity and delay sequences: delay between when artist is telling which square to colour and the factual colouring of it in the sign factory. Then, after the information has been delivered, an enamel painting was produced. There is a second delay between the second and third activity. After the physical paintings were sent to author, there is a third delay, or feedback which shows how the message was understood. Then, paintings are exhibited, the visitor/audience sees them, visual information is transferred directly to the viewer. The time between presentation and reception is the fourth activity sequence and delay.

We can describe this Moholy-Nagy's order of telephone painting in the terminology of an information model: sender, message, transmission, noise, channel, reception, receiver and feedback. Moholy-Nagy, the artist, is the information source and sender of information, in between there is noise - which is irrelevant, as we see - information was received by the supervisor correctly.

According to traditional understanding, delay in aesthetical communication could be defined as time which lies between completing the artwork by the artist and the perception of it by the viewer.

What I want to discuss is the disappearance or shortening of the delay between when the creator has finished the artwork and when viewer perceives it; and the situation where (by means of interactivity), the act of creation and the act of perception belong to the performative telecommunication artwork. Another interesting aspect is the inter-relation and exchange between creation and perception, so that perception and action, where it leads, becomes input for the next act of creation. There is a situation,

where presentation of an art object becomes a performance between the artwork and the user; it becomes time-based art where both the artist and the creator and receiver are taking part and where feedback from the receiver becomes input for artist, for the next stage of his creative activity.

Also, I would like to show that the delay between action and perception, or different sequences of activity, could be an essential building element - it could belong to a functional part of the artwork.

We can mention the delay which lies between instruction given by the artist and the execution performed by the same artist or somebody else, similarly with programming code which is written by the artist and will be executed by the computer or user.

3. PRE-DIGITAL ART EXPERIMENTS

I would like to characterize the fact that delay has been point of interest in earlier electronic artworks, bringing two examples: Richard Serra "Boomerang" (1974) and Dan Graham's "Time Delay Room" (1974). Works were done in same year and period, when experimental activity of artists' was internationally at the highest point.

To describe Richard Serra's work, I'll quote Rosalind Krauss sufficient description and interpretation, where she analyses artists' position inside the artwork, which is essential in video-performances built on feedback.

...a tape made by Richard Serra, with the help of Nancy Holt, who made herself its willing and eloquent subject. The tape is called "Boomerang" (1974), and its situation is a recording studio in which Holt sits in a tightly framed close-up wearing a technician's headset. As Holt begins to talk her words are fed back to her through the earphones she wears. Because the apparatus is attached to a recording instrument, there is a slight delay (of less than a second) between her actual locution and the audio-feedback to which she is forced to listen. For the ten minutes of the tape, Holt describes her situation. She speaks of the way the feedback interferes with her normal thought process and of the confusion caused by the lack of synchronism between her speech and what she hears of it. /.../

As we hear Holt speak and listen to that delayed voice echoing in her ears, we are witness to an extraordinary image of distraction. Because the audio delay keeps hypostatizing her words, she has great difficulty coinciding with herself as a subject.

/.../

The prison Holt both describes and enacts, from which there is no escape, could be called the prison of a collapsed present, that is, a present time which is completely severed from a sense of its own past. [3]

Nancy Holt finds herself in the "prison of a collapsed present" and such "self-encapsulation" is visible in other video artists works, for which Krauss brings projects by Vito Acconci as examples. In this context this example shows the essential importance of delay, it belongs to the form and concept of the work. Delay between spoken and heard text deeply penetrates the perception mechanism of the speaker. The speaker is distracted to such extent that she is not able to form sentences. Additionally we can speak about a metaphorical level of being in the "prison of a collapsed present".

The delay in Dan Graham work "Time Delay Room" belongs to the same sense. Visitor enters the room, where on one monitor he sees himself with 8 seconds delay, on the other screen view to the other room

with same situation. Here the visitor will experience an uncanny situation where he sees himself as almost real-time feedback image and recorded image in the same one image. Seeing himself as a delayed and mirrored image evokes intention to “freeze”, allowing image to “follow” the object, and intends to identify himself with the mirrored image through movement and action.

A game with the delay is visible in the Graham’s work “Yesterday/Today” (1975). Viewers in one room see a transmission from the other room but the sound recording has been made day before. As a result we see accidental overlap and divergence between image and sound. This two examples show us importance of delay and accident in the artwork. As a result there is constantly changing artwork, which challenges the viewer.

4. MULTI NODAL ART

There is historical internet artwork - Refresh project (1996), [4] by a group of artists and referred to as "Refresh - Art Project: Multi nodal net art", more than 20 WWW pages located in many servers of Europe and the US were linked together in a loop through which the visitor would be „thrown“ automatically after 10 seconds to another page. The project used a “refresh” meta-tag, a command within HTML. The command tells browser software of the PC of the user to automatically go to a particular page after a certain time. Refresh chain-pages take the user through all pages all over again. A refresh delay of 10 seconds is an integral part of the project.

Meta-tag looks like this:

```
<META HTTP-EQUIV="Refresh" CONTENT="10;URL=http://www.priss.org/fresh.shtml">
```

It brings user to the web site <http://www.priss.org/fresh.shtml>. But it could be any other site also, there where twenty of them.

Andreas Broeckmann wrote:

... the Refresh loop was designed to employ the interconnectivity of the computers and the software infrastructure to create one project that was simultaneously happening at more than twenty different locations, a genuinely distributed artwork whose experiential effect both depended on and transgressed the physical distance between the participants. [5]

Another example is "FragMental Storm 02" by Exonemo (2002).

"FragMental Storm 02 (FMS02)" is a type of web browser. It uses keywords to search the Internet and displays corresponding data onto the screen. In conventional web browsers the graphics and text shown on the screen are positioned in accordance with instructions included in the mark-up language HTML. In contrast, FMS frees text and graphics from their HTML, scattering them randomly over the screen. [6]

Before its use it should be downloaded to a local computer.

This work is constantly in redesign and regeneration. The result is changing, evolving and we can speak about another kind of delay, or waiting until the artwork complete (if the user ends it) or does not complete. It is endless - it is not repeating itself in detail, but still we can say that it becomes comparable, as it starts to look similar if we don't intervene by clicking and refreshing it. It reminds us rather time based art, looping video installation and it has been exhibited as installation as well.

We can say that the delay here is rather traditional, not like in the Refresh-project, where it was an integral part of the artwork. Here the viewer or user is “requesting” visual composition. After that programmed code retrieves visuals and text from the Internet in real time and mixes them, it plays with them “creatively”. The viewer in fact is “ordering” the artworks next phase and it is “performed” and “delivered” to him. Everything is based on functional software designed by the artist.

We can describe all artworks which are defined as “participative” or “interactive” in the same sense. Artwork changes or presents its variations after user input, it gives feedback, and it talks back. Dependant on the complexity of the software or hardware it could happen more or less interestingly. A dialogue is taking place between the artwork and the user.

5. DIALOGUE AND DELAY

For describing the specific quality of telecommunication art, Eduardo Kac has used the terms “dialogism” and “dialogical art”. Kac [7] wrote that “there is a clear difference between dialogical art and interactive art (all dialogical works are interactive, not all “interactive” works are dialogical)”. Also, he wrote: “dialogical aesthetics is intersubjective and stands in stark contrast with monological art, which is largely based on the concept of individual expression.” [8]

Kac writes that the roots of contemporary dialogical art experiences can be traced back to this arc of experimentation ... —from modern avant-garde collaborations and interactive propositions to the dematerialized and participatory events of the sixties and seventies. [9]

Telepresence art offers dialogical alternatives to the monological system of art and converts telecommunications links into a physical bridge connecting remote spaces. [10]

After Kac reason for appearance of dialogical art is „... increased dissatisfaction with concepts of art centered on the individual and on romantic heroic myths...”

Shortly we can describe dialogical art as art which produces new content during interaction with it and that the artworks’ physicality or visual, audible or other content is changing. The artwork is not the same in beginning as it is in the end.

I’ll bring for example a work by Nurit Bar-Shai, an online performance in three acts - “Nothing Happens” (2006). [11] The author describes it as interactive telematic mixed media live streaming installation with custom made software:

Nothing Happens, is a networked online performance in which viewers work together to make a series of objects tip over. The performance consists of three acts, which are centered around staged environments - a high shelf, a cluttered tabletop and an empty floor. Each scene contains a central protagonist, respectively: a cardboard box, a glass full of water and a wooden chair. In all three acts, web-enabled physical devices, controlled by viewer’s clicks, make these objects tip over. When this happens, the performance is over. [12]

The website allows physically distant observers a chance to participate. In one direction, the site displays live images in real time of the current as it unfolds. In the other direction, users are able to click a simple interface in order to manipulate the scene.

The key aim of interactivity in this performance, as the artist writes, is to create an immediate and understandable form of interaction, so that each click of a user is rightfully perceived as developing the scene further. [13]

In this work we see paradoxically real materiality elements which are part of the telecommunication artwork. The user and participant operate in a real time factual distant reality, like an operator is manipulated with hands of robots in space. The internet performance of things is linear, it has beginning and end. The result is predictable, but different in its speed. Naturally, real-time transmission or bandwidth influences the execution speed of the clicks and the speed of refreshed images on a website where we see tipping objects.

This discontinuity of internet performance, that it could be defined as an act-and-wait strategy, is similar with other interactive artworks where the user acts and waits for feedback. Here we see that the delay between images, which is defined by the transmission speed of the network, defines the activity of user. The slowness and predictability of the performance gives the user an opportunity to follow the process, it really fits with internet speed. We can expect a possible rupture of communication if the speed changes, if it gets faster and the view on the installation is not refreshed with sufficient speed. The user cannot follow the performance. Not this one, probably, as it is predictable, but some other event of remote controlling.

In case the user meets a non-predictable installation, each act of the user is defined by changes of the artwork. The same is happening in real dialogical situations in human communication, where questions and answers could be random, even the topic could change and new content could possibly emerge.

6. CONCLUSION

The speed of data transmission defines the delay between acts of communication (which could be an act of creation and an act of reception) as much as processor speed defines the execution of algorithms in a computer which allow selecting more complex tasks to realize. It means that images with higher resolution could be rendered or videos with higher frame rate could be edited. Higher speed of transmission and short delay in real-time communication gives the possibility to follow much quicker movement of a distant object and to see a much higher resolution of images.

Importance of delay in interactive and telecommunication art:

- Delay in traditional communication sequence, between creator, artist and receiver/user/viewer is becoming shorter and we see even disappearance of delay in this communication act.
- Viewers meeting/encountering visual art, interactive art and telecommunicative art is time-based performance, which could be divided into reception and feedback sequences, where delay plays important part. Length of delay influence content of artwork.
- Delay between different elements/sequences of time-based telecommunication art is integral part of the work, like pause is integral part of the musical piece. Time sequences where nothing is happening, where viewer is waiting (for feedback from artwork from local computer or distant server) is becoming part of the time-based interaction between artwork and the viewer/user.

NEW MEDIA EDUCATION IN A CHANGING ENVIRONMENT OF PSYCHOLOGICAL, PROFESSIONAL AND SOCIAL CONDITIONS

RAIVO KELOMEES

I would like to look at new media education from the point of view of psychological, professional and social problems.

Is artistic imagination influenced by the medium of expression? Is imagination renewed with new media? I mean new media in general – new technology, new tools? Is talent specific to a medium or is it universal? If we call anybody talented, then his talent will appear anyway, despite technological or social conditions, or not?

Net-Poetry 2, 1997, Nelli Rohtvee, Internet-project, <http://lizard.artun.ee/~nelli/nellinet/net1.html>

I will deal with the issues related to psychological, professional and social matters in art and art education in relation to new media.

1. Psychological problems

One question deals with the identity of the artist in relation to creative means. To what extent is the artist's imagination and thought process "new" because he or she is dealing with new media? Can we say that the artist's thinking renews itself after the emergence of new means of expression, that technology influences artistic expression? Can one say that if someone is talented, then there is no difference in what medium he or she uses? Is talent medium specific or is it universal? Can a talented person break through in any circumstances or does every talent require a certain configuration of conditions and means to blossom?

The artist's chosen medium influences how the artist understands himself. Art mediums are different from the point of view of the self-presentation of the artist, the difference being in how they "take in" and represent the author. Some means and mediums are better for observing and picturing the outer world and others are more as means of contemplation and self-observation. From time to time some

means of use of art mediums take on the parameters of mania or art form. A certain trend and movement emerges during which a floating manifestation is taken by groups of artists and it spreads as a virus.

One could notice manic manifestations in the 1990s when new media and digital technology entered the art scene. Artists were excited and the amount of production was unprecedented. Some works that surprised 10–15 years ago seem ridiculous. But some works that seemed ordinary and too simple with their “boring human problems” seem exciting now. They have stored the time and the people, showing us that irrespective of time and medium art deals with human existential questions.

Elation about the medium is natural when artists are excited about the nature of creative means. Subjective excitement about new means is similar to enjoyment that comes with new clothes, books, a car or a house. It is a time when things seem new, reality seems new and the whole life seems new. This is what factually takes place: the medium, the means and the creative environment that artists use does not only change them and how they see themselves, but also how they see the world.

Here we can recall McLuhan, who wrote that every society and time has its dominant medium – audible, written or visual. Mediums influence how people think of themselves and the world. When people started reading books, an opportunity rose to escape the earlier collective world, where they were connected by sound and sight. Books and new media at the time pulled them from the physical world to the imaginative and mental world.

In this sense art mediums are a means of interpreting the world and one’s self. Using them, artists describe who they are and what the world around them is like. Artistic mediums can be seen as a shield, a screen of sorts and a tunnel, through which the artist sees the external world. The ambivalent function of the medium is obvious as a means of self-reflection – art as a mirror and a window. From this point of view we can describe almost any medium in art history: artists used these mediums to reflect themselves and view the external world.

Still, it seems that the most important parameter of an artist’s identity is motivation, the willingness to be seen in action in his or her own field. To possess skills to say something is always possible, while to obtain willingness to say something is not. It either is or is not. Maybe this is “talent”, without which it is impossible to describe the author? The author’s motivation is this “author’s blood” that makes it possible to separate those who are creators and those who are not.

2. Professional problems

Eternal questions: how qualified should the artist be in technically implementing the medium? How much should he know how to use software and have computer skills to work as an artist and author of new media?

We can ask the same about traditional art. How good of a drawer must a painter be to be a good painter? We can also ask: how much skills and knowledge must a new media artist have so that he could be called a new media professional, a “very good” professional?

How much does an artist have to have skills to express freely and forget the “weight” of technology? It is a question without an answer, the scale is not set. And the criteria are certainly not objective. The usage

of skills is lead by the artist's mental preparation, which leads the "dosing" of skills depending on creative needs.

The notion of "new media professional" is kind of pointless, but it could also be seen in a narrower meaning, without ascribing expertise the person in every sub-section. In an ideal case we are dealing with a multi-specialist – and there are few of them. The "multi"-domain contains elements such as sound, video, graphics, hypertext, and programming and if we add cultural competence and economic expertise, we get the attributes of a third millennium artist.

There are several viewpoints in the question of new media and technological competence. First, a lot of works have been created with a simple unique message, which is not so much dressed in means of new media, as it is born using means of new media in a very simple way. New media is not merely a carrier of information; it is also an organic environment where art is born. Take for example Olia Lialina's „IF YOU WANT TO CLEAN YOUR SCREEN“(1996) [1] and Nelli Rohtvee's („Net-Poetry 2“, 1997). [2] Remarkable works of art have been created by top technological specialists and work groups, that "speak to" the universal and the human and are not hermetic, meant for a circle of experts. A fitting example is "Osmosis" (1995) by Char Davies.

3. Social problems

I have dealt with this issue in the article "The Forum of Latera E-Mail Group," [3] which described art social transformations in the Estonian art of the late 90s. Art collided with new "hot" digital mediums. People that had earlier set in the art hierarchy could not find anchoring points. But here one should stress the part of art education and changes taking place in the social environment that influence art education.

If in a political and economic sense it is accustomed to view the last 20 years as "liberation" and "renewal" then in a mental and social sense one set of rules has replaced the other. From the viewpoint of eternity there is no estimated valence. The main parameters that describe the social set of rules are three domains: the distribution of information, resources and reputation.

All of these we have seen before but the present society is different, as these have been remarkably integrated with art education. The same has happened in the art life as a whole. This integration means that the fight in this field has obtained a meaning of existential fight. The most important goal of achievement is the ensuring of meal and survival. To observers this seems as a specialized, professional or pedagogical activity; as a very refined, thoughtful and cultural activity.

In the landscape of information gathering and reputation creation the fight is being fought over guaranteeing maximal resources for one's own activity. The connection is definitely direct, but not absolute. The borders exist because whatever highly reputed pedagogical initiative does not automatically serve maximal resources; will not find reward nor living space from society; if its existence even remotely damages the interests and territories of existing artists.

There seems to be space but it is not handed out. At some point a situation of power play emerges – who is after whom? Who has a louder voice and a better lobby has a better chance of winning. The content is of secondary importance. The persuasion of the public and the deciders of one's advantages is the core of the game. Activity and aggressiveness can achieve a lot on this level.

The entrance of new means of creation to the field of art education in this way is characterised by three everlasting spheres where change and changelessness can be noticed: the psychological, professional and social aspect. These are the self-determination questions of the author, the questions of defining the level of professional activity and the social influence to the previous. Definition battles in the field of the creation of meaning in society directly affect the artist's identity and the assessment of the quality of his or her actions.

CALCULATING THE CURVATURE OF CROCHETED PETALS – A POST-MEDIA EXPLORATION OF DOMESTIC CRAFT-BASED TEXTILE PATTERNS

GAIL KENNING

This paper explores opportunities for extending the possibilities craft-based textile activities, through dedicated software tools to explore and interrogate textile processes. It reports findings from an experimental art project to produce software as tools for creativity in craft-based textile activities and advocates a rethinking of craft-based textiles beyond 'fixed media'.

Digital media and new technologies are ascribed a seminal role in the perceived increase of craft projects, do-it-yourself (DIY) culture, the production of user-generated media content, and user-led participatory practices (Gauntlett, 2011; Jenkins, 2006). The rapid development and accessibility of sophisticated audio visual technologies has reshaped media production and consumption enabling amateur photographers, film-makers, writers and musicians to utilise digital media not only in the production of their work, but also in its storage, dissemination and consumption (Jenkins, 2006). Digital media also offer the potential to extend and reconceptualise craft and DIY projects including domestic craft-based textile activities such as knitting, crochet, weaving and lace making that have been considered and seen as limited to physical 'hands on' activities.
