Digital media and new technologies allow expansion and reconceptualisation of these types of craft activities in four ways. They facilitate the distribution and sharing of project templates, patterns, instructions and 'how to' information across geographic, social and cultural borders. They also enable users to display images, videos and information about completed projects. Third, digital media create audiences and communities through online forums and viewing spaces. Finally, and most importantly, they offer the potential for the development of tools, such as software applications to allow users to extend and explore their own creativity.

This paper shows how digital media can extend and reconceptualise domestic craft-based activities using experimentation enabled by the production of dedicated software tools for craft-based textile practitioners. It draws on an ongoing experimental art research project which interrogates domestic craft-based textile processes in an effort to examine the creative potential of craft-based textile pattern forms and argues that there are potential social and cultural benefits from the development of tools for creativity that aid experimentation and exploration.

The project advocates a rearticulation of craft-based textile activities beyond 'fixed media' and embraces the non-media specific nature of craft-based textiles which have operated as text, in diagrammatic form, as threads, and more recently as pixels, bio-materials, mathematic functions and computer code.

Craft-based textile activities have a long and complex history. The textile fragments that have survived inform our understanding of the development of techniques and pattern forms. In addition, woodcuts, booklets and magazines, paintings, photographs, and notebooks and journals reveal craft-based techniques, patterns and styles and attest to the longevity and importance of craft-based textile activities as a creative practice (Shepherd 2009).

The mass media play a role in promoting craft activities and DIY projects in relation to fashion and trends through magazines, pattern booklets and 'how to' styled TV and radio programmes (Greenhalgh, 1997; Johnson, 2005; Schofield-Tomschin, 2001). In observing that "both the amateur arts and crafts are undergoing what has been described as a 'boom time'" (2004, p269). Turney suggests that this renewed popularity is due to increased levels of education, participation by women, an ageing population, and

more access to leisure time as a result of the changing nature of societies and their workforces (Turney 2004).

These activities are what David Gauntlett (2011) describes as acts of 'everyday creativity' and are important to both individual participants and society as a whole. Jenkins (2006) suggests that they bring about "a changed sense of community, a greater sense of participation, less dependence on official expertise and a greater trust in collaborative problem solving". Craft activities and DIY projects fulfil a desire to make or be involved in a creative process (Gauntlett, 2011, Turney, 2004). They may be seen as expressions of symbolic creativity: of the drive to create. Turney (2004, p276) argues that "symbolic creation is an essential part of everyday life and a demonstration of the real and ideal self" (2004, p276). Certainly in relation to domestic craft based activities, there are many reasons for promoting the continuation of these activities at a grassroots level. Craft-based textile activities have been cited as being important in the continuation of tradition, the development of creativity, in providing a sense of community, in the construction of personal identity and for healthy ageing (Schofield-Tomschin, 2001; Johnson, 2005; Minahan, 2007; Turney, 2004). These acts of 'everyday creativity' are self-driven, self-directed and self-fulfilling activities (Atkinson, 2006). The number of practitioners, the level of commitment, enthusiasm and labour invested in 'everyday creativity' without tangible reward suggest that these activities are driven by intrinsic motivation – that is "for its inherent satisfaction rather than for some separable consequence ... for the fun or challenge entailed rather than because of external prods, pressures or rewards" (Ryan 2000, p56).

However, while these acts of 'everyday creativity' are in abundance, the level of creativity involved has been subject to criticism. Craft-based activities, including textile activities, are accused of being 'low', repetitive, manual, non-creative, non-challenging, requiring little or no skill, and of little value in relation to the arts (Atkinson, 2006, Greenhalgh, 1997, Turney, 2004). Turney suggests that "the marginalization of home crafts from academic discourse is largely based on an understanding that both practices and objects are 'uncreative', repetitive and mundane, existing outside the world of the innovative, creative, challenging avant-garde" (2004, p268). These activities draw criticism because of their seeming culture of duplicating, copying, and the recycling of pre-existing forms, and their reliance on pre-designed kits, patterns, and templates (Turney, 2004, Atkinson 2006) suggests that kits patterns and templates are in effect 'dumbing down' craft, which he suggests is part of their attraction.

This culture of copying causes concern in relation to the standardising effect it has. For instance, Pen Dalton says "the encouraging of dependence on projects from women's magazines, patterns and pre-designed kits, however well designed and demanding of the patience and skill of the housewife, has had a standardising and largely detrimental effect on craft practice" (as cited in Atkinson, 2006). My PhD thesis argued that the continual recycling of crochet lace patterns and the focus on the production of an object had seemingly resulted in a stasis in the pattern form and that the creative potential of the activity is yet to be fulfilled (Kenning, 2007). While mainstream radio, TV and magazines contribute to the seeming renewal of popularity, there are concerns that they also contribute to the standardisation of these activities as a result of the scale of production and distribution of kits, patterns, magazines, books that encourage the construction of similar popular patterns and projects (Beegan, 2008). Websites, blogs, television programs, books, and magazines encourage and promote craft activities by providing 'how to' articles, templates and patterns, and instructions for 'personalised' rather than experimental or self-explorative craft projects. Such projects equate creativity with the customisation or individualisation of prescribed forms.

This paper proposes that it is to digital media and new technologies that we might look for new tools for creativity, and that they may offer the potential to extend these forms of activities and reveal a form of 'everyday creativity' uninhibited by the strictures of the template, the pattern, and the seductions of the mass media.

Before examining how experimentation can be introduced through the use of digital media, it is useful

to explore why there is a seeming lack of experimentation and acceptance of this culture of copying in 'everyday creativity'. Jenkins (2006) suggests that these activities emerge at a grassroots level, are learned through informal education, and arise out of shared traditions (Jenkins, 2006). This gives rise to a sense of responsibility in relation to the continuity of these traditions which inhibits experimentation. In addition, both Jenkins and Turney suggest that the lack of innovation and experimentation may be due, in part, to many 'everyday' craft practitioners being educated to primary and secondary level and having an institutionalised view of what constitutes art, design and craft and what is considered acceptable experimentation within those fields (Turney, 2004). Such participants often need to be given 'licence' to extend their creativity beyond the conforms and confines of their formal or informal teaching, pattern books and kits.

Recent developments in craft-based textile activities have resulted in young participants applying innovative approaches to craft activities in the form of guerrilla crafts, S&M knitting and yarn bombing (Kenning, 2009). However, for the most part, these experimental approaches remain in the minority.

The impact of digital media on acts of 'everyday creativity' involving filmmaking, photography, video, music, and so on, has been discussed at length and is evident on websites and social media sites across the Internet (Jenkins, 2006). However as previously discussed, domestic craft-based textile activities have until recently primarily used digital media as communication tools, and it is only now that we are beginning to see the development of software applications that may be used in the production, rather than distribution, of domestic craft-based textile activities. Developers of these software applications and digital media tools, include craft-based textile practitioners who want to speed up the design process; craft product suppliers who wish to extend their range of products or increase sales; software developers that have recognised a growing market for applications that can visualize craft forms; and open source developers who are interested in sharing both craft instruction and code.

Examples of digital media developments include mobile applications that are being used as aggregators of news, information and videos about craft projects and techniques. Another software application, Knit Visualizer represents text instructions in diagrammatic form to enable quick referencing during physical construction of textile objects (Foundry, 2010). Some applications translate text instructions into computer code to visualise and modify patterns online (<http://stitchworkssoftware.com/>). One open source project knitml aims to standardise knitting instructions and create a mark up language for knitting to enable any knitting pattern to be rendered and visualised. However, many applications continue to act as communication tools or visual design aids. In these examples the media (code, algorithms, pixels) used do not manipulate or influence the pattern outcomes unlike in the physical environment where the media, the choice of threads, hooks, technique etc impact on the final form produced. In addition, these software applications neglect the processual and procedural aspect of domestic craft-based textile activities and do not engage with the processes inherent in both craft-based textile activities and digital media. Thus they do not provide a platform for true experimentation.

With limited approaches to experimentation the risk remains that domestic craft-based textile activities will continue to copy and recycle pre-existing patterns forms and projects, and will fail to escape the on-going criticism regarding their lack of creativity and not achieve their creative potential. Whereas the digital environment can offer valuable insight into the making process, and the potential to provide a greater understanding of how craft-based textile activities and patterns can develop, and how creative possibilities can be extended (Kenning, 2007).

In discussion of textile activities in relation to digital media, domestic craft-based textile activities are frequently positioned as physical, material and tactile and contrasted with digital media which often cited as lacking physicality, materiality and tactility. While this view is contested and arguments have been made for the materiality and tactility of digital media, it is not within the scope of this paper to explore these arguments in detail (Munster, 2006).

When participating in domestic craft-based textile activities engaging with the media, that is physical

threads and fabrics, is often assumed to be the motivation. However, research suggests that the issue is more complex, and while engaging in a process is important the construction of a physical artefact is not the primary reason (Atkinson, 2006; Johnson, 2005; Minahan, 2007; Schofield-Tomschin, 2001).

This tension between what we might consider the creative process and the output occurs in other activities. Activities manifest in a range of media other than what would be their expected material form. For example, materiality produced using chemicals and paper is no longer required for photography. For many, only the skeumorphic click of digital cameras and Photoshop icons remain as clues to past physical processes. Similarly, architecture such as Liquid Architecture has no intention of realising the architectural forms as physical structures. In addition, we might also think of the relationship of the musical score and the written play to the performance. The score and the play can and do undergo rigorous critique in absentia of the performance. These examples point to potential for creative opportunities beyond a single medium.

Freed from the constraints of being manifest in physical threads, domestic craft-based textile activities participants are free to explore not only the processes of domestic craft-based textile activities but also computational processes of the digital environment to exploit algorithmic variation and explore mathematical functions. My PhD thesis identified that craft activities can draw on computational possibilities for AI and explore potentially evolutionary and emergent possibilities in the digital environment and in the physical realm. This enables new forms, patterns and shapes that have been difficult to make, imagine or understand before sophisticated computational possibilities to be modelled in a range of digital media applications and realised physically through hardware and peripherals such as 3D prototyping. This ongoing experimental art research project to explore creative possibilities for domestic craft-based textile activities has undertaken a variety of approaches. A range of findings from the project have been presented at the Textile Society of America Symposium, ISEA 2009 in Belfast and, more recently, at the Subtle Technologies festival in Toronto.

Initially the project took the form of a software application to mate and mutate domestic craft-based textile activities patterns. However, limitations were imposed, not by the media itself, but because of the teams' understanding of what constituted craft-based textile patterns and their expectations. The application enabled users to mate and mutate patterns, but the parameters were restrictive because they initially focussed on the appearance of the pattern forms. In addition, aesthetic judgement was applied too early in the process and prevented patterns developing beyond conventional forms. The second stage involved aligning the algorithm in digital media with the decision-making process undertaken in physical construction of the patterns. This involved, in effect, neglecting the final form and focussing on the placement of individual stitches or motifs in relation to the last stitch or motif made whether the position was correct or not. Thus, glitches and errors in any part of the process were embraced and often became exaggerated in subsequent rounds, leading to the creation of seemingly random forms. It allowed for the creation of pattern forms that could not be created without the use of digital media.

Both of these areas of investigation are ongoing. However, the more recent developments have focussed on the construction of motifs in order to reveal the unacknowledged mathematical formulae that underlie many of the shapes used in Irish crochet lace. The work identified mathematical formulae that create visually similar forms and then used these functions to manipulate the motifs and extend the form. A crochet lace collar from the Powerhouse Museum lace collection in Sydney was used as the source material. The lace collar, which was crocheted in 1850, consisted of four primary motifs repeated at intervals. The motifs were representations of nature, the daisy; shamrock; rose; and spiral form, and can also be described using mathematical formulae such as $y=n$.¹⁴ As simple mathematical formulae, the variables can easily be changed allowing for the overall patterns to be manipulated quickly and effectively. The pattern becomes a product of the design of the maker and computational processes.

Thus, pattern-making in the digital environment allows for a range of systems to impact, interact, intertwine and intervene with each other and can harness generative possibilities, mathematical systems computer code, and craft-based textile techniques to stimulate domestic craft-based textile activities and create new possibilities.

A post-media approach opens up new possibilities, affording potential for experimentation in a form of creativity that has not been previously examined in this way (Manovich, 2002). It allows for the discovery of new forms and new ways of making and creates new sites of 'everyday creativity'. For those not familiar with digital media or computers, digital media allow exploration from a position of strength by focussing on DCBT processes already learned. For those familiar with digital media, experimentation enables users to explore new ways of making and may stimulate interest in making new pattern forms in the physical realm. As well as its implications for creativity, development of craft-activities beyond the manifestation of physical objects also has potential health and welfare benefits as it frees users from the requirements of materials and physical dexterity, affording whole new ways of working which can be particularly important for the elderly and those with injuries or disabilities.

These creative processes can be made readily available to older participants who have an in-depth knowledge and understanding of craft-based activities both in terms of a tactile engagement with materials and in the construction of textual instructions and diagrams, but have limited dexterity. For them it offers ways of stimulating the mind and hands through ongoing making processes through for example patterns generated through voice recognition or sound. These participants are often keen to remain both physically and mentally active. Therefore, digital media tools for creativity present opportunities to prolong involvement with pattern making activities promoting both physical and mental stimulation. In addition, digital media offer the potential for work in groups through networked activities and for example interactive table-top.

Digital media tools for creativity may provide benefits both physically and mentally. This is particularly advantageous when we find that people are increasingly identifying themselves in terms of their creative outputs, and symbolic creativity rather than their job (Castells, 2000).

ENTREPRENEURS, SQUATTERS AND LOW-TECH ARTISANS: DIYBIO AND HACKERSPACE MODELS OF CITIZEN SCIENCE BETWEEN EU, ASIA AND USA

Denisa Kera

The global spread of alternative R&D places outside the universities and corporate labs offers an integrated model for art and science cooperation and public participation in science. These places (Hackerspaces) and projects (DIYbio) offer a direct involvement of citizens in the R&D process in term of translational and participatory research. What are the opportunities and challenges of these novel institutions across the globe?

The research for this paper was conducted as part of a grant from the EU centre in Singapore “Participatory policy model for emergent technologies: comparative study of alternative R&D spaces in Singapore and EU.”

While media, government, non- and inter-government organisations were speculating on the size of the Fukushima Daiichi nuclear disaster and discussing issues of nuclear safety, standards and policy measures, individuals and small groups of citizens involved in grassroots science activities around the world were measuring, monitoring and crowdsourcing real-time radiation data over DIY tools and sharing data over the web. [1] This agile and resilient response to a situation of insecurity and lack of data was initiated by people around the Tokyo Hackerspace [2] and their friends from Portland and Los Angeles with connection to the global Hackerspace community. [3] It resulted in creation of a platform, Safecast.org, over which data on radiation are gathered from almost 300 nodes [4] and which also serves as platform for supporting creation and distribution of DIY Geiger counters.

Hackerspace community is just one of the examples of Do-It-Yourself (DIY) and Do-It-With-Others (DIWO) initiatives that are emerging in recent years everywhere around the world challenging our views of citizenship vis-à-vis emergent technologies but also disasters. Fukushima disaster in April 2011 showed how this informal network of Hackerspaces around the world was able to react and coordinate efforts in developing low-tech tools which Akiba, the uber-hacker from Tokyo Hackerspace, poignantly named “Humanitarian Open Source Hardware.” [5] These DIY tools were distributed over another recent prototype of a service, a community market for open source hardware, InMojo. [6]

This immediate, decentralized and global response to a disaster goes way beyond the common but also imagined forms of solidarity and innovation. Crowdsourcing not only ideas but also materials for building DIY Geiger counters and even prototyping and designing new tools such as the Kimono Solar Lantern Kit, a hackable solar powered lantern for \$12 named after a bar next to Tokyo Hackerspace, or iPhone Radiation Dock (iGeigie), portable Geiger counter, present a new type of global and participatory design which combines solidarity and innovation. [7]

These prototypes directly connect technological standards (open source) with deliberations on social action in a global and day-to-day context via various DIY and experimental management techniques. They bring together politics, technology and nature in a direct and transparent way that offer resilient and open structure for participation and decision making. Control and decision making (in terms of monitoring, reflecting and self-organising) are instantly connected to scientific facts, laws and technological

standards via design prototypes, which are political, social and technical at the same time. Design in the case of radiation data becomes a form of participatory but also global and collective action redefining the relations between lay people, science experts and political representatives. Furthermore, the speed of the response, including the actual design of the prototype and the launch of the participatory monitoring of radiation platform over Safecast, took impressive 72 hours of work by enthusiasts from several Hackerspaces around the world. [8]

The Hackerspace infrastructure that made possible the citizen science response to Fukushima was already in place long before the disaster and it is used not only in the case of software and hardware innovation but also in the case of so called DIYbio research specializing on various aspects of biotechnology and even medicine. Similar movements and places define an alternative R&D structure that uses design as a convergence of social and technological innovation. These small scales, experimental, alternative R&D structures represent a convergence of several radical ideas around development of open source software and hardware (Hackerspaces), [9] cheap and open source, digital fabrication (FabLabs), [10] citizen science labs crowdsourcing biotech research (DIYbio), [11] innovative coworking and management structures (HUB). [12] These innovative, coworking experiments paradoxically combine the squat and publically funded culture of the EU art centres with the market driven entrepreneurship rhetoric of the US start up scene to envision research and innovation outside the traditional professional settings of universities and corporate labs. The insistence on low-tech solutions and open source technologies democratizes the whole R&D process to a degree that it makes it possible for developing countries to join as we can see in the case of Fablab in Africa [13] and Afghanistan [14] or the now famous “House of Natural fiber - Yogyakarta new media art laboratory” (HONF) from Indonesia. [15] HONF founded in 1999 is not only one of the oldest alternative R&D place outside of EU or US, but also the most original, because of its unique combination of influences and its relation to the local community and culture. It is an artists’ run organization that is occasionally funded by EU (for example their recent Fablab) thanks to their global art network connected to a festival of new media art which attracts the EU crowds with access to money. However, it is also a coworking space and privately funded organization that is supported by its members in a manner similar to US based citizen labs and Hackerspaces with occasional contact to the local universities and companies.

While in 2008 and 2009 the whole alternative R&D movement gained a momentum in terms of popularity thanks to various citizen science research projects related to Hackerspaces but also DIYbio labs and the Maker’s community, the 2010 marks the start of the global movement which proved its usefulness and resilience in the recent Fukushima disaster. The global movement is defined by various events around the world that identify with the idea of citizen science projects, low-cost and low-tech protocols, lab equipment based on open hardware and shareable and reproducible kits. The common strategy of connecting the DIYbio labs to the local Hackerspace communities is widespread even if it is not the only model. The more socially and critically involved hacking similar to EU art and DIYbio centres is typical for most of Asia DIYbio and Hackerspace scene while Singapore seems to follow more the US orientation to entrepreneurship and personal enhancement. Experimental forms of research, investment and even artistic creativity show clearly how the “low-tech but high-impact” logic of the DIYbio and Hackerspace movement operates in various contexts and how it can connect science, culture and society in ways that traditional policy and public participation in science research could not even imagine.

The artistic and scientific solutions and protocols are affecting but also involving large groups of citizens and stakeholders in the process of the research, creation and innovation. Whether in US, EU or Asia, the Hackerspace revolution involves open source laser cutters and other open hardware tools that can create cheap lab equipment, enable synthetic biology recipes and other protocols to spread like cooking

recipes, self-organized clinical trials and other community related projects that are challenging not only in technological but also in social sense. The strategies and interests of these groups are slowly converging into one informal network between Asia, US and EU enabling very different flows of knowledge and expertise. It also paradoxically embraces, develops and combines two extreme strategies of R&D, on one side the market driven entrepreneurship model following the US, on the other side, the anarchistic, underground model of the EU based squats.

Various forms of bottom-up organizations that appear in recent years around emergent technologies, DIY subculture and novel forms of investment in innovation and entrepreneurship provide interesting case studies for studying the relation between politics and design, new technologies and social movements, emergent “non-humans” in Latourian sense [16] and transforming society. Whether we are speaking of alternative “R&D labs” that are part of some existing cultural and art centres such as Ars Electronica in Linz, ZKM in Karlsruhe, FACT in Liverpool, Laboral in Gijón, or alternative incubators like Hackerspaces, HUBs, MAKE fairs etc. we can witness the crucial role of radical design and politics play in connecting humans and non-humans and experimenting with new networks. The emergent networks are not simply explored by these institutions but actively performed and created by novel forms of research, investment and even artistic creativity and social experiments around open source laser cutters and other hardware, synthetic biology recipes, sharing and discussing DNA data, self-organized clinical trials, various types of performance software, robotics and any simply any emergent technology. [17] Communities of people monitoring, sharing and making sense of various “objective” and “scientific” data in their everyday life are actively exploring and performing the future symbiotic relations between various types of agencies across scales. The true cosmopolites of today are people actively involved in platforms such as Patchube, [18] Carbongoggles, [19] DIYbio list [20] etc. exploring the emergent, often surprising connections, networks, and mashups between different actors and scales.

From nano- and bioart exhibitions to annual new media festivals, various museums of the future and alternative incubators we are witnessing public involvement with emergent sciences and technological inventions that go across business, art and research. The various functions of such spaces from the more obvious like popularization and presentation to the more professional like investment in innovation to the more creative and experimental like envisioning our common future the goal is similar to the early ideas and vision of science, technology and art interactions. It is to foster and accelerate the ability to connect various actors in new networks and ecologies across scales. [21]

The strange paradox in this new type of DIY, citizen science projects and institutions is how the increasing involvement of the public goes in parallel with the as intensive emergence of new actors across scales. The non-humans seem to talk a lot lately via various data that we are able to generate, gather and visualize in the citizen science projects that involve low cost monitoring, sharing and interpretation of various data but also in various hacker and maker projects. The public interest in data defines these new communities intimately connected to their environment on various scales from molecules, DNA and cells to institutions and cities (BioWeatherMap, [22] EpiCollect, [23] and CamMobSens [24]). We are even starting to witness large, bottom-down projects envisioning the future cities as microstates and software platforms performing such new ecologies and systems (Digital Cities, City 2.0, Intelligent Urbanisation, Cities-as-a-service, Smart+Connected Communities, Cisco's New Songdo, IBM “Smarter planet”, HP “Central Nervous System for Earth”). [25] The cosmopolitical future is in connecting actors across scales via data and creation of new dependencies, metabolisms, systems, networks which do not make a difference between the organic and non-organic actors, between the social, political and biological, but create new relations across scales.

These interactions across various scales and not only actors (atoms, molecules, cells, humans, institutions, cities, planets) seem crucial in terms of connecting design and politics. These networks between heterogeneous actors and across various scales hold the key to any future hybrid communities which we are starting to witness with the alternative R&D. While most projects dealing with future communities and issues of sustainability and/or biodiversity still concentrate on the scale of animals, plants and large ecosystems, the interest is slowly shifting to more complex interactions between humans, microorganism and molecules on the micro-level that often defines new communities and micro-ecologies through sensor data. The data we gather about our bodies (for example DNA), society (like mobile use, consumption etc.) and nature (CO₂, radiation, whether, bacteria) are integrated over various platforms and interfaces to help us understand the unique equilibria but also develop and create new habitats. The various functions these experiments from the more obvious like popularization and presentation to the more professional like investment in innovation and more creative and experimental connect politics with design, social innovation with prototypes. These DIY and alternative places perform, foster and accelerate the ability of science and technology to serve different purposes and connect various actors in new networks and ecologies. The very democratic form of these institutions that support bottom-up and citizen science projects defines them as true cosmopolitical laboratories and defines cosmopolitics not only as experiments with novel networks between actors but more importantly between various scales. The main issue of cosmopolitics for this reason is not a problem of the subject-object, animate-inanimate relations but issues of interaction between scales, relation between parts and newly defined wholes.

Furthermore, all these citizen science and bottom-up projects that gather various data, actors and connect scales strangely revive the pre-modern ideas on human and non-human interaction like bestiaries and cabinet of curiosities and the original project of the “Academy of sciences” envisioned by G. W. Leibniz that also speak of such radical hybridity. [26] These novel forms of community organised and financed science and technology labs revive the original idea on science, technology and public interactions envisioned by G. W. Leibniz in his famous “Odd Thought Concerning a New Sort of Exhibition (or rather, an Academy of Sciences ; September, 1675).” In this original vision of the academy of sciences Leibniz ceases to discuss the advancement of sciences and technology in terms of metaphysical and philosophical issues of truth, limits of human mind or the nature of reality but defines science and technology by their ability to generate new ecologies of interest and influence, new institutions, networks and relations between different actors. Science, technology, business, art, entertainment, tourism are all part of an effort to raise human curiosity and wonder and transform the society. Leibniz's prophetic vision of cosmopolitics modelled after his ontology of monads and interactions between different scales is a reality today in the case of hybrid organizations such as Ars Electronica in Linz, ZKM in Karlsruhe, FACT in Liverpool, Laboral in Gijón, numerous small centres around the world and alternative incubators (Hackerspace, DIYbio, HUBs) that connect art, design, technology and sciences in often playful and unexpected ways. SECURITY GATE 26.11

John Kim, Anthony Tran & Vasily Trubetsky

Security Gate 26.11 is an electronic artwork that detects wireless emissions given off by individuals, including cellular transmissions, wifi, RFID, and others. By our participation in informational networks, we actively volunteer information about ourselves to forms of surveillance. Security Gate 26.11 renders visible these invisible mechanisms of discipline and control and documents our participation in possible tyrannies of our own creation.

AUTHOR(S)

Conceptual rendering of Security Gate 26.11 by Molly Reichert.

Metal detecting security gates, such as those used in airport screening, are the sites of discipline leveled against the body. As recognized by Michel Foucault, on our bodies converge different mechanisms of control, as issued by the State, biomedical technologies, and capitalist pressures. For your average traveler, airports have become sites of inconvenience and embarrassment, because of full body scanners, “enhanced” pat-downs and lengthy waiting times. But for those who are profiled because of their ethnicity or political views, airports are sites of humiliation and indignation. This discipline is justified because airports are liminal spaces where the normal right to privacy is increasingly in suspension.

Security Gate 26.11 is an Arduino-based, interactive, electronic art work that detects wireless emissions given off by individuals, including cellular and smartphone transmissions, wifi, Bluetooth, RFID, and others. Security Gate 26.11 produces individualized audiovisual responses to these transmissions. Our lives are subjected to daily forms of micro-level surveillance via mechanisms that are not recognizable to us as such precisely because they are not visible. Today, wireless transmissions are the corpus of control and repression, as evidenced by sophisticated governmental systems of mass surveillance and snooping (Carnivore and its variants) and corporate monitoring (data-mining and software recommendation systems).

The internet provides us with indispensable communication tools in exchange for the ruthless commodification of our lives. Online we constantly volunteer intimate details about ourselves to capitalist appropriation and governmental surveillance. Facebook, for example, is a tool to share and communicate with your closest friends and family, but it constitutes one of the most extensive and detailed records of personal information ever collected about people. The disastrous political consequences of online disclosure have been demonstrated too many times in the last few years. Even when they pay lip service to privacy rights, corporations are in the business of making money and have with only with token resistance handed over private information about its users to governments out of fear of jeopardizing their bottom line.

Many of us know this already, and yet we continue to voluntarily subject ourselves to this pervasive scrutiny. Mark Andrejevic has referred to our knowing participation on networks of surveillance as the ideology of interactivity. It is personal self-disclosure as entertainment. Nineties’ webcams have become today’s social networks. The difference is that we no longer have a choice but to join these networks. They are tools that do not just enhance our ability to communicate with others, but have become integral to what constitutes human contact. To some, the fact that I do not post regular status updates on Facebook might imply that I do not have a complex social or emotional life, but to others, it simply means I do not exist. Our lives are the informational traces that we leave for others to browse.

We’d like to reflect further on details about the particular design of Security Gate 26.11, in particular, its detection of electromagnetic frequencies and the shift from analog to digital wireless transmission of information.

From an Electromagnetic Spectrum to Digital Presence

Access to information networks is increasingly done wirelessly (e.g. cellular networks and wifi), that is, transmitted via electromagnetic radiation. Since the explicit formulation of the laws of electromagnetism over a hundred and fifty years ago, scientists and thinkers have accepted the existence of electromagnetic fields as a natural phenomenon, despite the fact that they are not visible to the naked eye.

That is to say that the existence of electromagnetic fields is now acknowledged just as we accept the existence of atoms or stars.

The advent of digital signal processing has both abstracted information and also enabled a rapid expansion of the amount of data that can be wirelessly transmitted. Instead of analog's continuous signal, digital data is quantized and sent as discrete pulses; a signal, in effect, becomes independent of the medium in which it is transmitted and becomes simply information. Because data is abstracted in this way, digital signals are no longer legible in the same way as analog's modulation of frequencies. Each frequency can be used as a carrier of binary information, dramatically improving the capacity of electromagnetic waves to carry information. This change has facilitated the development of pervasive and always on wireless digital communication devices.

Conclusion

We are not in control of our digitally enhanced lives. We are unaccustomed to thinking about the informational traces we leave about ourselves. Many of us have yet to wake up to the realization of how extensive and pervasive our lives are subjected to constant monitoring through our use of communication technologies. Security Gate 26.11 renders visible the invisible information that we give off about ourselves. The Gate confronts us with our digital presence in the form of aural and visual feedback to the electromagnetic frequencies that we give off.

A second reading of this situation, already implied in this paper, is more pessimistic: we already recognize our predicament, yet we have no choice but to participate. In April of this year, for example, Apple was forced to admit that it collected and stored a year's worth of information about our physical location and movements, a database constituting a record of unprecedented micro-level surveillance. The public's shock at this revelation seemed disingenuous. That Apple was doing this wasn't at all surprising (it is well known that many of the electronic devices that we carry around in our pockets facilitate extensive monitoring), but the public, nevertheless, registered shock as a kind of toothless protest at the disclosure of this level of fine grained monitoring. Apple's response, that it needs to collect this information in order to provide the services we demand, is, to some degree, accurate. Heightened disciplinary monitoring is necessary for the functioning of pervasive and always on digital communication technologies.

In both these readings, the conclusion is the same: we have no choice but to participate and render our lives transparent to pervasive surveillance. Security Gate 26.11 brings to light the costs of our participation in digital networks by rendering visible these invisible mechanisms of discipline and control. The Gate demonstrates our voluntary participation in possible tyrannies of our own creation.

BODY GRAFFITI: EXPRESSIVE WEARABLE ART THROUGH BODILY PERFORMANCE

YOUNGHUI KIM

A wearable art itself can be an expressive media platform and when it is worn by a performer, it elevates expression of body language combining two forms of media that have been so close to art and technology - wearable and performance. This paper introduces "Body Graffiti", a performance wearable art project that uses the illusion of POV (persistence of vision) technology to create ephemeral graffiti via bodily movement.

Fig 3. Body Graffiti v.2, The Swing Boots, 2011, Younghui Kim

Introduction

Like many fine artists with technological background, modern & experimental dancers in the age of digital media have been early adopters of wearable technology. It seems obvious as the wearable itself can be an expressive media platform and at the same time, worn by a performer, it elevates expression of body language as creating a stronger media platform combining two forms of media that have been so close to art and technology - wearable and performance. This paper introduces “Body Graffiti”, a performance wearable art project that uses the illusion of POV (persistence of vision) technology to create ephemeral graffiti via bodily movement. The artist creates and utilizes this newly developed wearable platform in order to express and communicate her contextual messages and suggests the significance of creating a “wearing” technology art project by presenting the creative development process, as well as future variations of “Body Graffiti.”

Background

About a few decades ago when wearable technology was introduced as a new form of human-computer interaction, a small group of media artists with technology background paid a great attention to it as a new form of expressive media to explore. Today, wearable technology has become more accessible to designers and artists and wearable has become a new subject of research for its abilities to transform physical interface of information technology into clothes to wear. While they were in search for innovative new flexible technology solutions, many found out that wearable computing facilitates a new form of human-computer interaction because the user can compute by one's body while wearing it. Furthermore, interaction can be operated by simple bodily gestures or its surrounding elements such as noises, temperature and WIFI signals while walking or doing various activities.

There have been great interests by artists in wearable as a form of new media art since it brought out innovative significance in communicative art. Especially in interactive dance or performance like N.I.M.E. (New Interface for Musical Expression) artists can take full advantage of expressive choreographies of wearable technology media. Diverse experimental wearable projects have been showcased at the international exhibitions like ACM SIGGRAPH Cyber Fashion Shows, FutureFashion Event, Seamless, Social Fabrics and more during 2000s.

At a glance, Interactive wearable computing seems to be a natural adaptation of physical computing as clothing is ubiquitous with physical interface. In a comparison with portable devices like mobile phones, one can see obvious behavioral difference between being 'wearable' and 'portable.' The computer being wearable introduces drastic changes in how we communicate and compute. Further more, fashioning element enhanced with interactive technology creates a new form of computing media that is more responsive and expressive for both creators and wearers. This shows that not only wearable media brings the new condition of wearing an actual computer on body but it also introduces significant changes in ways a user computes using one's body whether its a gesture or a temperature body emits. Therefore wearable art can be investigated for being a powerful means for expressionism of everyday life activities and performances through interaction.

Body Graffiti

The "Body Graffiti" projects started with a simple idea for a new performable digital media public art that doesn't require a stage set or a big screen in urban streets. Performers like B-boys(Breaking dancers) are originated from street art scene just like graffiti artists, and they can be defined as public art performers. There is no simple definition of street art yet, here is how the online publication; Art Radar Asia defines 'street art'.

With anti-capitalist and rebellious undertones, it is a democratic form of popular public art probably best understood by seeing it in situ. It is not limited to the gallery nor easily collected or possessed by those who may turn art into a trophy. Considered by some a nuisance, for others street art is a tool for communicating views of dissent, asking difficult questions and expressing political concerns. [1]

Graffiti arts are drawn in urban public space to communicate messages whether they mean political or not. You can find tap dancers or b-boys in public streets or parks in urban cities like Seoul or New York City, performing outside of structured theatrical environments. Combining elements of strong graphic message with the street performing art, the POV driven technological platform for "Body Graffiti" was invented in a wearable format using basic electronic technology with a microcontroller embedded hardware, Arduino. [2]

Observing the performers like B-boys who express in their fierce body language, the idea of enhancing their bodily expression using wearable media reacting to their dancing motion, was conceived in 2007 when the artist moved to Seoul to teach and research further in interactive art. She had been looking for new collaborators to experiment POV technology on wearable costume for dancers to test on POV displays with their movements.

In 2009, the WCU Digital Media Public Art Research Lab [3] was founded with a support by the Ministry of Education, Science and Technology through the National Research Foundation of Korea. As a participating researcher, the artist was able to develop the newest prototype of "Body Graffiti" wearable project.

The wearable project requires to be designed with a great knowledge in both art and technology combined. Thus, it requires a long process of researching in various materials and technologies as well as developing an actual working prototype in a breadboard and then, clothing. Especially for dance performances, the wearable garments had to be comfortable and durable from fierce bodily movement. Additionally, unlike of the other physical computing applications such as installations and interactive objects, wearable computing applications force artists to de-construct the conventional 2-dimensional electronic circuit system and rewire into a flexible 3-dimensional electronic circuit system transforming it to be integrated seamlessly into soft clothing design with strong wearability. [4]

The Body Graffiti for the b-boy performance had been an on-going collaborative project from beginning. There had been multiple prototypes of "Body Graffiti" in collaboration with the world champion b-boy crew, 'Last for One. In this performance wearable project, the artist tested the POV system interacting with specific dancer's movement with a couple of small testing prototypes first.

POV, Persistence Of Vision is the phenomenon of the eye by which an afterimage is thought to persist for approximately one twenty-fifth of a second on the retina. A common application is a flipbook animation. POV display is a technology that composes an image by displaying one spatial portion at a time in rapid succession (for example, one column of pixels every few milliseconds). In the project, "Body Graffiti" has used 2D POV display technology accomplished by means of rapidly moving a single row of LEDs along a linear or circular path. The viewer can perceive the image as a whole as long as the entire path is completed during the visual persistence time of the human eye. A further effect is often to give the illusion of the image floating in mid-air. [5]

With a technical collaboration from the fellow researcher, Dan Mikesell, the artist made a jump rope using 8 LED pixels at first. The POV image was somewhat recognizable in bare eyes during the jump rope swings so, she moved to the next version using a LilyPad Arduino with 16 smaller red LED pixels and hand-sew the whole circuit using 2-ply conductive thread. When wearable computing projects are involved, the LilyPad Arduino, designed by the Sparklab [6] and Leah Beachley, [7] conductive thread or fabrics, metallic connectors like snap buttons, and light batteries are common ingredients. The second small prototype was sewn into a pair of sneakers where LEDs were embedded on the outer layer. However, after the first meeting and rehearsal with the b-boy team, it was soon realized that POV display on the sneakers limits the visibility of the graffiti message because of the breaking dancers' certain angle of movements.

The next sewn circuits with an LilyPad Arduino was purposely made on the small pieces of fabric in order to attach on different spots on the performer's body since wearable has to be designed according to dancer's speed and angle of movements; rotation such as head-spin in the case of break dance. After test-rehearsals with two b-boy dancers who specialize 'head spin' technique, the research team soon found the best suitable spots on the dancers' bodies to perform "Body Graffiti" – chest, back and from ankle to knee part of both sides of legs.

Once wearable forms are decided to be a vest and a pair of leg shields for the better visibility of graphic and textual message to be conveyed, the whole new system was developed quickly. The new system

was built with the custom PCB (Printed Circuit Board) where electronic parts were hand soldered to control 32 LEDs with an Arduino Nano. The electronic circuit and software had to be redesigned and reconfigured to support more number of LED pixels. With this new system, the very first finished version of "Body Graffiti" was developed successfully and performed during HCI Korea 2010. [8]

During the performance, two main b-boy dancers wore the Body Graffiti system embedded in the vests and leg shields and expressed visual graffiti drawn in air, with their body movements. As b-boy dancers perform head spins, windmills and flares, messages programmed in the custom designed LED POV system was displayed. The visual messages for the HCI Korea 2010 performance were graphical icons like a pointing finger and a heart beat with words such as – 'HCI 2010', 'Open Creativity', '창조', a noun meaning 'creativity' in Korean, to emphasize the main theme of the HCI event, "Open Creativity". Therefore, one can say that the performance of the Last For One dancers wearing the "Body Graffiti" was meaningful for its collaborative and creative effort.

Future Projects

The "Body Graffiti" art projects continued to evolve in both contextually and esthetically after the performance with the b-boys. First, the system has been upgraded with more defined custom PCB design that has become thinner and more flexible with the doubled resolution of a vertical column of 64 LED pixels, where more detailed images can be displayed in the POV display. Also, newly designed PCB has become modular, so that each unit of 8 LEDs can be added up to 64 LEDs when connected together. Each unit can be connected with electronic wire or conductive thread through the connecting sewing holes on the PCB modules, in order to construct the electronic parts into a flexible wearable piece and also to fit better with 3-dimensional shape of human body.

The design variations of the "Body Graffiti" interface have been an on-going exploration. The second variation with the newly upgraded electric circuit system has become a pair of black boots with a column of 64 LEDs each, titled "Body Graffiti, The Swing Boots." The wearer can perform the POV graffiti display on the swing set like one that you see in the playground, or just swing her legs back and forth fast to display POV message. Contextually, it is still in an experimenting stage for the swing boots wearable project. During the exhibition at DALSM 2011, an exit sign graphic following with a text of "RUN" was performed while swinging the boots. [9] On a swing set, the swinger wore the boots to display the POV graffiti images of a pair of wings on both legs along with a word, 'FLY.' One could imagine, when the "Body Graffiti" swing boots are made in multiple numbers, the wearers could be marching in a formation to demonstrate certain textual messages in public space as an urban performance.

For the newest variation of "Body Graffiti", the context of exchanging meaningful message matters heavily. The audience would catch the moment of movements of lights and remains of its prior existence; the existence of the brief visual text message created by blinking LEDs a brief moment ago. In this version, it is not actually a wearable for the performer but multiple numbers of objects that anyone can perform to throw – they are the "Body Graffiti" Frisbees, working titled as "Throw & Catch (Words)." Each disc will display two words when it is thrown up in the air to be caught. Words are carefully programmed and embedded into the "Body Graffiti" POV platform system by the artist. This project is to demonstrate the physical form of communication through bodily movement, throwing and catching certain words that briefly exist. The project, "Throw & Catch (Words)," was displayed, and performed at the Tukksom Han River public park in Seoul, Korea on the 21st of August, 2011 as a part of a group exhibition titled, "Media Circu(it)s." There were about twelve "Body Graffiti" discs laid out on the grass near

Han River and the public was invited to participate in throwing words around in the evening. The different texts in Korean meaning such as 'I'm better than you', 'I don't want to', 'I envy you' were POV displayed for participants to experience communicating in physical action of throwing and catching the briefly existing textual words that are commonly uneasy to speak out within Korean society, where this art project was exhibited. This new version is to be developed further in different languages in close future.

Conclusion

'As a wearable communication platform, an electronic textile functions as a dynamic surface around the body that interconnects people and places.' [10] Often, wearable artists take great deals in displaying since the surface of the garment easily becomes visual interface to communicate. Lights are common form of visual expression in wearable technologies since it's easy to control their patterns and movements with micro-controllers.

In some sense, "Body Graffiti" performance with the b-boy crew, "Last For One" was a true form of hybrid art and collaborative creation among dancers and wearable art technology researchers. Like other performing wearable musical interfaces and/or real-time moving images that interact with wearable on performers, it reflects how performing art can be an ideal platform for the wearable media as it provides creative expression for both wearable artist and performers.

The fact that messages for the "Body Graffiti" projects can be reprogrammed easily through the software developed in Processing and Arduino makes "Body Graffiti" a wearable platform. The project wasn't originally created with a functionality of a wearable in mind. Rather, this new wearable display platform was created in the process of exploring context of words and graphic messages displayed through bodily movements of the wearer. Very often, new media artists have to create or reinvent a new technological platform in order to express in new ways and this was the case for the project, "Body Graffiti." Additionally, very expressive ability of the platform opened up new opportunities of creating many different variations of the "Body Graffiti" projects as a result.

"Body Graffiti" isn't just a new wearable platform. It is a statement the wearable creates through performer's bodily movement and the artist's conscious messages combined. Its fast movement and transformation leaves a brief story while blurring its surroundings for its audiences.

RETHINKING THE BASELINE: EXPLORATIONS IN NONLINEAR TYPOGRAPHY

Travis Kirton

Rethinking The Baseline is an ongoing investigation into the possibility of non-linear typesetting through the production of original artistic software and exhibited artworks, which challenge fundamental concepts in the field of typography. Two digital canvases are presented, called TextDraw and Typels, where the artist can draw with text using nonlinear and gestural interaction to control and create new kinds of typographic aesthetic.

Fig 1. *The Don's Imagination*, 2009, Travis Kirton, Handmade Typographic Artwork / Print made with Typels, 1.80m x 1.0m containing 450,000 letters.

Fig 2. *Drawing with Type*. Putting pressure on the pen changes the size of each letter as it is being drawn, tilting the pen changes opacity, and drawing direction affects rotation.

Fig 3. Baselines (in red). Traditional baseline (above) is an invisible staff which appears after letters have been typeset. Weighted baseline (below) is an object made of points which determine the characteristics of the letters on the line.

Aspects of modern typography that were defined around the time Gutenberg's press was presented to the world have come to be deeply rooted in daily perception. We take for granted the way words should be read, how text should be prepared and presented, to such a degree that "good" typography should often become transparent. This level of achievement has come through centuries of development, and many theories for working with text have stood the test of time. The work presented herein does not challenge the beauty of a letter, the aesthetic qualities of an optical kern value, nor the gestalt effects and theories which were studied and concretized throughout the better part of the 20th century.

What this work suggests, however, is that the digitization of the typesetter's workshop brought with it strict and rigid principles that belong within the realm of materials. For instance, principle of "leading" refers directly to the use of lead as a medium for creating space between lines of text. Beyond this, however, the remediation of typesetting also brought with it a methodological and linear process of working with words. A process whereby the act of placing one letter after another, of moving one block of text, changing characteristics of letters, and so on, happens in a step-by-step fashion. Furthermore, the abstraction from metal type and typesets to the mouse, screen and keyboard, effectively abolished the physical nature of typography. No more do the typesetter's hands get dirty during the creation of a new work.

The direct translation of typesetting techniques to the computer was a necessary first step. Now as new forms of technology are arising, computational devices are becoming faster, and physical interfaces are moving away from the keyboard and mouse, it is the right time to start thinking about the next stage of typesetting. This work attempts to do just that. The confluence of digital typesetting, computation as a medium for artistic expression, and the advent of graspable and tangible interfaces creates an incredibly interesting and open space for the field of typography.

MOTIVATION

My goal is to develop new mechanisms that help us *rethink* our relationship to things we take for granted, and which can provide a foundation for the development of innovative approaches and new space for creative expression. At the moment, my work looks at a limitation in modern typesetting environments which shapes the practice of typesetting into a linear one. Through my research I have come to see this limitation as a by-product of design for keyboard and mouse interaction.

I share in the belief that this linearity occurs as many elements of digital typesetting environments have been developed as general remediations of printing press techniques. [1] In response to this, I have created a new kind of canvas for working with type using non-linear techniques, where many aspects of a letter, word or phrase can be controlled and manipulated simultaneously.

My technical approach finds its roots in two places: the use of computation as a medium for creativity, and the development of physical interfaces for high-fidelity interaction with software environments. The former can be seen in the work of contemporary computational artists who develop their own programming languages, writing software through which they are able to express their unique visions. [1,2,3,4] The latter can be seen in the development of Tangible and Graspable Interfaces which provide more natural affordances for control and interaction than the keyboard and mouse.

Such kinds of interaction have been successfully applied to gaming, music, storytelling, and other computationally enhanced environments, but remain largely unexplored in the field of typography. [5,6,7,8] I am interested in developing new kinds of software / hardware interfaces as opportunities for returning to the field of typography, a physical quality that was lost when print moved to the screen.

GESTURAL & NONLINEAR TYPOGRAPHY

Over the course of the last two years I have been engaged in a media-art research project centered around the idea that smart interactive surfaces can help us rediscover and rethink paradigms that we take for granted in our everyday lives. Throughout this period I developed two applications, called TextDraw and Typels, which exemplify the possibility for non-linear typesetting through original artistic software. As well, I used these applications to produce and exhibit artworks that support a challenge to fundamental concepts in the field of typography. Furthermore, both of these applications utilize elements that separate them from modern commercial typesetting software.

The act of creating, or even simply attempting to create, new mechanisms for production opens up an opportunity to deeply investigate the nature of a field such as Typography. In order to build something new one must first understand the elements needed for its construction. In the past, such elements were almost entirely material, or physical objects and processes – before being able to punch-cut moulds for casting type, an understanding of physical properties of metal alloys was essential. In today's digital world such elements can fall entirely within the realm of the intangible – creating new applications for typesetting requires a working knowledge of available underlying software frameworks. Both cases necessitate a thorough understanding of the qualities of the materials with which one can create.

The production of TextDraw and Typels has helped validate two fundamental assumptions about the field of typography. Despite the potential for digitization to untether typesetting practices from their

historical precedents, the act of typesetting remains inherently linear. This linearity is strongly influenced by the tools and materials with which typographers are able to accomplish their practice. Additionally, since the introduction of new forms of media and techniques in the mid-60s, of which software plays an important role, the physical nature of the practice of typesetting has been largely lost.

The first application, TextDraw, addressed the linearity and lack of physicality present in modern typography. It did so by considering the impact of new technologies on the ability to provide a paradigmatic shift towards non-linear control over typesetting environments. TextDraw is designed to be used with a stylus that can capture such things as pressure, location, tilt and rotation. These aspects provide the basis for capturing a variety of movements and hand positions which can be used as gestural input for typesetting. In doing so, TextDraw attempts to do so by bringing back elements of lost physicality, through the creation of gestural interfaces which provide higher degrees of expressivity than the traditional keyboard and mouse. [9]

GESTURAL TYPESETTING IN TEXTDRAW

In typography, the baseline is an implicit element used for measuring the vertical placement of text, which Bringhurst describes as an invisible line “on which [most] letters rest.”[10] The baseline is an implicit element because it only appears as a result of typesetting, and is not a real object in the sense that it can be changed. In software, however, the baseline is an explicit object that contains letters.

Creating baseline itself as an explicit object, which provides the basis for defining text attributes, is a different approach than the one taken by modern typesetting softwares. Essentially, in abstracting attributes away from individual letters I am attempting to shift the idea of the baseline from an imaginary entity to one that is also responsible for creating the look, position and feel of text itself. Rather than the baseline arising from the visual composition of text, it is the visual composition of text that arises from the creation of the baseline.

In TextDraw, gestural interaction is captured and stored in a set of weighted points which contain position, rotation, pressure and tilt information. When a path is created, by drawing a line into the application’s canvas, it takes a section of text and attributes each letter based on its position along the line. As each letter’s attributes are determined, those attributes help determine the position and attributes of the following letter. Specifically, the attributes for every letter in a line are dependent on that letter’s distance from the beginning of the line, with its distance being dependent on all the letters which precede it along the line.

Modern typesetting software breaks bodies of text down into lines, and then into runs of characters. These runs are essentially sets of sequential letters which have the same attributes (e.g. point size, font, italic). In TextDraw, it is uncommon for individual characters to be lumped into the structure of a run because the fluid and intuitive nature of gestural typesetting often provides subtle variations in attributes from one character to the next. Because of this, it is the attributes of each individual letter are determined by its distance from the beginning of the line on which it is being drawn. Furthermore, because each letter’s distance determines its attributes the concept of a run of letters having common characteristics becomes obsolete. In general, the reason for this obsolescence comes not from the technique of gestural typesetting but from something more fundamental.

The principle behind the idea that text can be broken down into lines, and then into runs of characters, which all fit within shapes and areas in a typographic composition presupposes something crucial. The metaphor behind the construction of a basic run of characters supposes that all characters will be consecutively laid out on a line. This is an important point, and fundamental to this work because this approach assumes that the traditional concept of an implicit baseline as a horizontal or vertical element is the most appropriate form for typesetting in a digital context.

Having created TextDraw, I took a 6 month hiatus from developing to focus solely on working *with* the application, rather than *on* it. I was able to “draw” with type, but wasn’t really sure what that implied. So, I started exploring the differences between inked lines and lines of text. Working solely in black and white for this period, I produced a series of works whose aesthetics were largely based on versions of various woodcut prints by Gustave Doré. I was able to trace lines using my pen’s pressure sensitivity to smoothly adjust the size of each letter as I was drawing.

Afterwards, I experimented with shading and the qualitative aspect of using text as texture, subtle adjustments to the tilt of my pen changed the opacity of each letter. The product of these experiments were the Alice in Avenir series, where I combined chapters of Alice in Wonderland with images from its original publication. Through this period of creative work I learned much about the artistic experience of gestural typesetting. However, I felt that the process of creating works with TextDraw remained inherently linear because the application only moved through a text one letter at a time. To move beyond this I needed to develop a system which would handle moving through a text in non-linear fashion.

NON-LINEARITY IN TYPEIS

Naturally, the technique of gestural typesetting is a non-linear one and requires more than a straightforward, linear access to the text which is being drawn. In order to accommodate this, a novel line management and text storage system was designed into the new application. Among many advantages, including efficient storage and access, Typels provides non-linear access to various components of a body of text. When a body of text is loaded into the application, it is broken up into a set of component strings, each of which can be accessed individually. Even though the current implementation uses a pen-based interface and draws a single line at a time, it is possible to access multiple components of a text simultaneously. In a simple experiment, a bit of modification to the user interface resulted in a multitouch version of Typels where each finger is drawing words from different parts of a text.

Just as I stopped developing and started working creatively with TextDraw, I picked up my stylus and spent again a period of months experimenting with Typels. Throughout this period I moved beyond black and white experiments to a range of works in colour. With the sophistication of new system, I was also able to create interactive installations and 3D-printed type sculptures. During this period I also collaborated with the choreographer Joan Karlen to produce dynamic poetic aesthetics for the ballet Trace.

RETHINKING THE BASELINE

Represented in these two applications is a fundamentally new way of constructing typographic works. This new way can be seen as the result of using a new kind of mechanism, a weighted baseline, a software object which attributes characteristics to letterforms. This mechanism provides the ability for

recording multiple forms of input which provides the opportunity for non-linear control over the aesthetics of a piece. The non-linearity which is possible through the use of this baseline is supported by another mechanism which provides non-linear access to all the elements of a given text. The weighted baseline shifts the typesetter's traditional practice of editing characters and words to manipulating the elements of a typographic environment.

Typels attempts a first, though small, step towards bringing physicality back to the practice of typography through the use of gestural interaction. An overall vision, and motivation for the work, sees the development of tangible interfaces for typography where the typographer can once again actually touch and control the tools needed for typesetting.

Rethinking The Baseline implies that its purpose is to investigate modern typesetting and to propose new inventions where old mechanisms may have reached their potential. It suggests, too, that new technologies provide the starting point for reconsidering paradigms that are taken for granted in our daily lives. Finally, and most practically, it elucidates the fact that the creation of gestural and non-linear typesetting environments require the invention of a new kind of baseline.

In traditional typesetting the baseline is an abstract idea, an ephemeral line which appears only after letters have been aligned to one another. In TextDraw and Typels, the baseline has become an object that the typographer can mould and create through gestural and non-linear interaction. A new object, which becomes central to the creation of artistic works, provides the starting point for rethinking established ideas and paradigms of thought. In a synthetic media-art-research practice, new mechanisms provide the opportunity for the creation of new aesthetics, and new kinds of expressive activity create the space for the development of practical innovation.

CROSSWORLDS

OLGA KISSELEVA

Products of the theory of error correcting codes, electronic tags correct transmission errors, exploit informational redundancy, flirt with order, disorder, and the entropy of information: in *CrossWorlds*, the artistic proposal integrates the concepts of a scientific corpus born post-war under the impetus of Claude Shannon. A true dialogue between art and science is presented here.

Fig 2. "Olga Kisseleva 'Have you enrolled as a volunteer?' from the CrossWorlds series, 2008

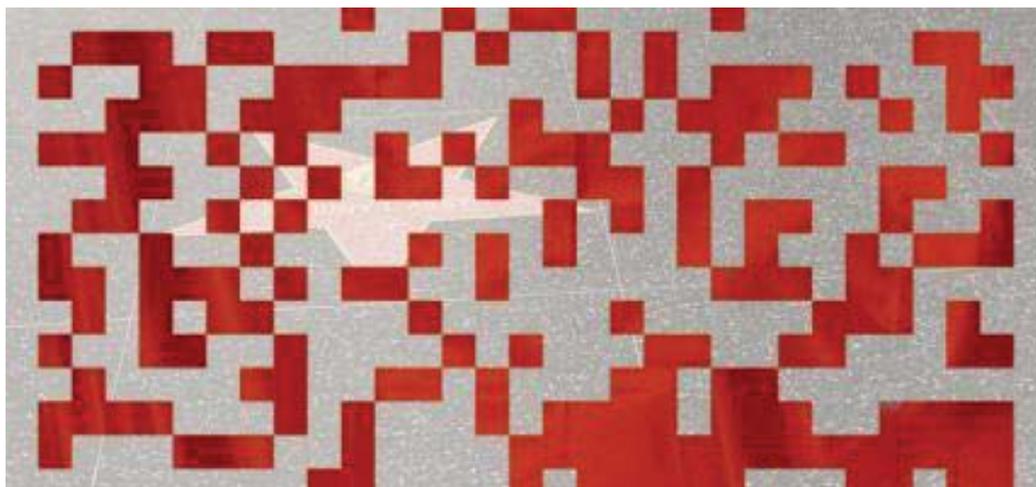

Fig 3. Olga Kisseleva 'Towards the collective' from the CrossWorlds series, 2008

The advent of the digital communication systems at the end of the '90s generated a major change in society. It is undeniable that this technological revolution profoundly modified the structuring of relationships between individuals on the one hand, and between the individual and the collective (e.g., governments, large companies,...) on the other. Using this fact as a kind of anchorage point, I have implemented an original collaboration between art and science, proposing an innovative development as regards a collaboration between artists and scientific laboratory.

My way of working follows an experimental approach: a discrepancy, detected during a process or in the operation of a structure, leads her to formulate a hypothesis, explaining the observation in question, and as far as possible, to propose a solution to the problem. To do so, she identifies the skills required to carry out the studies and pilots the research. I call upon the exact sciences, on genetic biology, geophysics, or political and social science. I carry out the experiments, calculations and analyses, strictly respecting the methods of the scientific discipline concerned. My artistic hypothesis is thus checked and approved with a strictly scientific method.

CROSSWORLDS: CONCEPT AND OPERATION

CrossWorlds is presented in the form of a series of electronic tags printed on formica.

This artwork was produced in the context of Transmediale, the theme of which for 2008 was "Conspire": hidden intentions, hidden messages, hidden things... The piece was created in situ at HKW, Berlin (Das Haus der Kulturen der Welt - the House World Cultures).

When entering this place for the first time, one can feel an atmosphere similar to that of the Soviet culture palaces of the Seventies (time when I, then a schoolgirl and member of the Communist youth, had piano and ballet lessons in this type of institution). However, the HKW is not a product of East Berlin. This famous building was offered by the Americans to the town of Berlin as a sign of friendship in the

Fifties, “to mark”, to some extent, their territory. As such, slogans of American propaganda were engraved on the walls of the building - in the figurative sense - as testimony of United States supremacy. What is surprising is that this building is similar to those which the Soviets were simultaneously building on the other side of the Berlin Wall.

I was particularly interested in this point, which led me to explore questions related to the similarity between the cultures of the Eastern and Western Blocs at that time.

ELECTRONIC TAGS: FROM FUNDAMENTAL PHYSICS TO THE TECHNOLOGICAL OBJECT

The electronic tags I use are semacodes, the two-dimensional modern version of the barcodes of the Eighties. Barcodes are omnipresent in the labeling of products or objects (hypermarkets, libraries,...), and are primarily used to ensure the traceability of goods. They are made up of a succession of black bars, the variable thickness of which represents respectively an 0 or a 1. They are, however, more than just a simple technique for the storage of digital information. Barcodes (like the majority of visual codes) are robust in relation to error: they contain informational redundancy, i.e., they contain more information than necessary in order to be able to correct possible misreadings thanks to this additional information (for example, if a bar is not easily readable, with weak contrast, and its thickness is consequently difficult to estimate). Each code has its own performance, which makes it possible to recover original information more or less effectively according to the level of error present.

A datamatrix is a two-dimensional version of a barcode. It's a square of a few square centimetres, made up of juxtaposed black or white pixels (or squares), respectively coding a 0 and a 1. They first appeared in Japan in the Nineties, and were rapidly adopted by the Japanese industry due to their high storage capacity on a very small surface (in particular their capacity to code the kanji of the Japanese language). They are also error correctors: if a zone of the square is blurred, or the level of contrast is weak, and the reading of certain pixels is therefore difficult, the informational redundancy is sufficient to recover the original information as long as the blurred zone is not too large.

The choice of the semacodes (a variant of the datamatrix) for the fundamental base of the work is also an aesthetic choice. The pictogram, which can contain up to 4000 characters, offers a sybilian, cryptic aspect to the eye, which also intrigues one because it is omnipresent in contemporary society, and yet indecipherable without the help of an electronic machine.

In as much as they are error correctors, the barcodes are de facto products of an obsession with security (food or medical safety,...) which increased throughout the Eighties and Nineties and was nourished by our society's growing intolerance of error, and somewhat ambiguous conception of risk (rendered positive when it's associated to innovation and the entrepreneurial, and deplored when it flirts with death - aeroplane accidents, medical errors,...).

The principle of error correcting by redundancy was formalised by Claude Shannon at the end of the Forties in his article “A Mathematical Theory of Communication”. Humans have their own mechanism of redundancy which enables them to communicate even under difficult conditions of transmission (ambient noise,...) for a long time: either quite simply by repeating the same sentence several times (collation mechanism), or by adding information another way (gestural), or finally by using contextualisation to decode the information (a word's missing in a sentence, but the context enables us to guess what it is).

In this last case, it's our culture, and our language, which enables us to recover information by contextualisation.

Semacodes are displayable as a two-dimensional matrix of black or white pixels. The visual analogy between semacodes and spins (models from quantum physics, like the Potts or Ising model, and intended in particular for magnetic materials) led me to explore the conceptual similarities between the physical model of spin networks (which has been studied for several decades, and which constitutes the paradigm of statistical physics) and the eminently contemporary technological object that is the semacode, further.

ELECTRONIC TAGS: THE ARTISTIC APPROACH AND THE TECHNOLOGICAL OBJECT

As an artist, I became interested in electronic tags for two reasons. The first approach was formal: she found this geometric form composed of small squares, enthralling from an aesthetic and a semiological point of view. The duality is present in each tag: black/white, dark/light, zero/one. Each time, the tag is like a path to be found in a maze, an enigma to be solved, a truth to be defined. I was seduced above all by the positive Cartesian side of these objects.

But, if the tags have a tempting appearance, from a social or political point of view they also have an alarming dimension. Often invisible, due to their small size, they are omnipresent in the urban landscape, public and private spaces, in the underground, on advertising posters, magazine covers... They differ from the barcodes that one finds on products for sale in supermarkets, in that semacodes are decipherable with a simple mobile phone equipped with a camera and necessary decoding programme (rather than a sweeping laser scanner). Once decoded, the message "enters" the telephone.

All kinds of messages can be adapted to tag technology: simple texts, or more complicated informational structures, such as an Internet address (URL), a hypermessage (sound, image or video), even an order which the telephone will carry out. In practice, when one goes past an advertising poster in the underground with one's telephone on and directed towards the poster, a message "jumps" automatically into one's telephone, inviting one to connect onto the site of the mark in question and buy the latest promotions or the latest models of the range. All one has to do is click on "OK".

We are, in fact, becoming increasingly manipulated by this technology. We have less and less choice: it's binary, between clicking on "OK", and not clicking. All the rest has already been prepared, the path has been paved.

I first came across electronic tags in 2006 during my exhibition at the Guggenheim museum in Bilbao. The project introduced the urban signalling used by people with a minor mental handicap to move around the city, into the museum territory. In several parts of the town of Bilbao where difficulties of displacement or orientation could arise (bus, street, crossing, etc...), electronic tags were present to help them by bringing them the necessary information. The handicapped were to some extent radio-controlled through the city by such tags. It was surprising to note how the handicapped people recovered the faculties of "normal" people thanks to this technology. And in fact, the non-handicapped people became almost handicapped by being inordinately assisted by this multi-media technology.

Obviously, it echoed Soviet propaganda technology used in the USSR, which hammered slogans from dawn to dusk, in nurseries, factories, and at home, that one should adhere to, such as: "do not stray

from the collective”, “love your fatherland”, “every day the lives of the Soviet people are increasingly happy.” One realised in the USSR that another kind of propaganda was being hammered on the other side of the iron curtain, but with a different set of values. When one looks more closely at the slogans of American propaganda, one realises to what extent they are close to Soviet propaganda (in particular when translating Soviet slogans into English, one can see how the same words are used). For example the very Soviet “the dreams of the people come true” is astonishingly close to the American “what the people believe is true”.

Each tag is composed of two images: one from Soviet propaganda, the other from American propaganda. Each time, one of the images plays on the black, the other on the white, and together they make up one of the slogans, Soviet or American. When looking at them, one can note a real similarity between the two images, for example between the faces of the Ukrainian dancers, and the faces of Hollywood actress, or more specifically, between Marilyn Monroe's face and that of Lubov Orlova (Russian actress who was the star in all Soviet films at the same time); one is under the impression that it's the same face. When one presents these two images to Western spectators, they think it's Marilyn Monroe's face shown twice. But it is not only a question of faces, but also of common symbols: in one of the tags one can see the red flag brush with a fragment of the floor in the Hall of Famed in Hollywood, with the same stars in the shape of a star personality.

INTERACTIVE INSTALLATION

An interactive CrossWorlds was produced in collaboration with quantum physics laboratory.

By inventing a computer programme which produces semacodes on the go when connected to the Internet, I wanted to divert the semacode from its primary technological function. The programme generates semacodes the original white and black electronic tag pixels of which change colour at regular intervals to ones which remind one of the “flashy” look related to the disco music period at the start of the '80s. This aesthetic choice is not random. The period also symbolizes the advent of perestroika and the East-West detente, and when the Berlin Wall were omnipresent in the political and artistic discourse in the West.

A true semacode does not fluctuate, the pixels do not change colour, the black/white opposition is thus disturbed here by an absurd colour setting, which doesn't contribute anything to the informational level, and even blurs the tag by reducing its contrast. The colour setting, in addition, is random; the choice of colour is produced randomly from a pallet of sixteen colours chosen for their saturated aspect. It is, in fact, a perfectly reproducible chance process, created by a computer program called “pseudo-random generator” which produces in a deterministic way, i.e., predictable and reproducible, a succession of numbers between 1 and 16 which have no apparent correlation between them. This absence of correlation is what makes the succession of numbers seemingly unpredictable, and therefore fittingly random. Following the example of radio operators used by the intelligence services of the former Eastern Bloc to jam and prevent the reception of television programmes produced by Western tv channels, these semacodes jam and thus access to the political message contained in the tag is more difficult. The exhibition visitor, provided with his or her mobile phone and an ad hoc decoding software, is therefore sometimes surprised that he or she cannot decode the message if chance happens to contribute to the situation by significantly modifying a majority of pixels.

CONCLUSION: ART&SCIENCE BASED WORK AS A NEW PERSPECTIVE OF CONTEMPORARY ART

The last two centuries have shown how much researchers, engineers, and scientists have had the capacity to change in the society in which they live, and which they've exerted via a process generally consisting of creating a filament (a new theory, technological invention), or suspending themselves from an existing filament and creating more or less rebellious ramifications of it. The researcher cannot not be responsible. The desire to address such a responsibility becomes more and more pressing over the process of his or her process of maturity.

Art&Science approach concentrates on destabilizing, and taking a certain amount of distance from, the daily practice of research, while taking a fresh look at past work; at the sensitive, laughable or provocative dimensions of the work, which are also fundamental, in that they can constitute a catharsis.

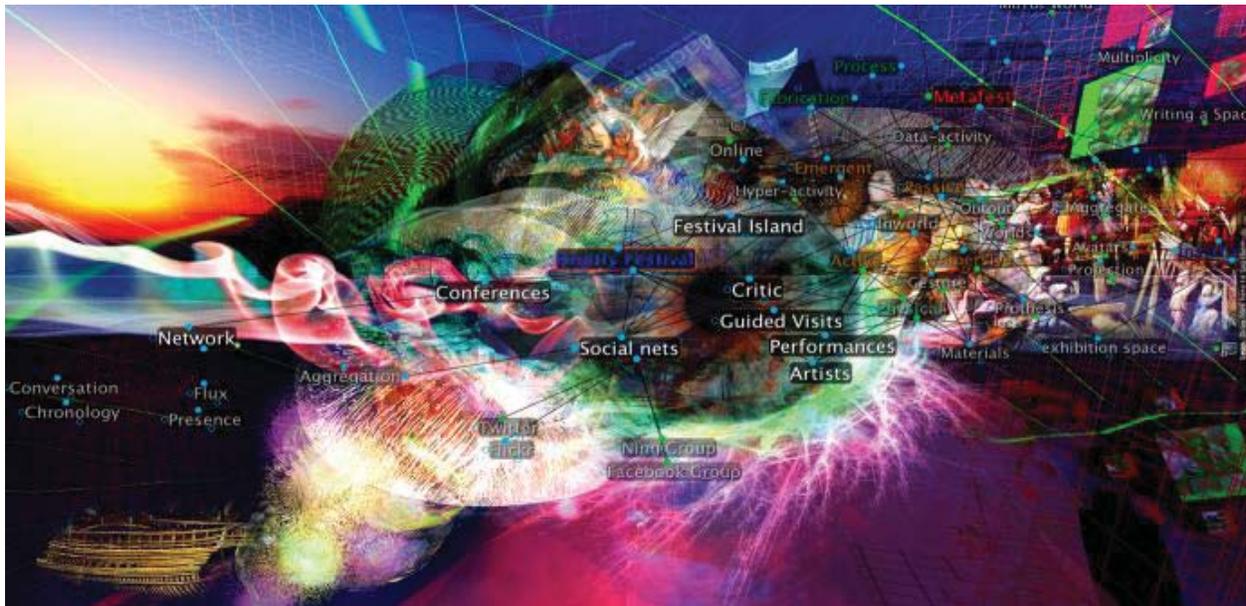

By analysing scientific theories since the second world war, it appeared to me that the theory of information was probably the most disturbing, stimulating, shocking and destabilising to have appeared in the 20th century. In the ultradigitalised information and knowledge-based society, in which the desire for hypercommunication is the rule, it seemed essential to us to propose that one reflect on the significance of this communication and on the structuring of the information implied within it. For the researcher, there is, naturally, a quest for meaning related to the societal implications of his or her work.

Art&Science research upheld by CrossWorlds, and the firmly interdisciplinary character of this approach, has enabled me to provide a resonance to this work that is scientific, aesthetic and political. Cross-Worlds has quite naturally given rise to the concept of informational resilience: resistance to censure, propaganda or truncated information, the fundamental role played by the redundancy in this resistance, multiplicity of channels of access to the information, intransigence to error or to jamming. Such key points will be refined, disclaimed, and put to the test, in future work.

INFRA|VERGENCE

Brad Kligerman, Jamil Mehdaoui & Sinan Mansuroglu

Immersive visualization reveal the dynamic form of communication and transportation infrastructures as it facilitates the simultaneous occupation of digital and physical worlds across, online server, virtual worlds, and physical space. A visualization of the metaverse's sustaining infrastructure emerge by mapping its form, structure, scale and extents based on usage data flowing through it, focusing on their divergent/convergent qualities.

(E)Space, immersive visualisation by Bradley Kligerman and Jamil Mehdaoui (Building W/Immaterials

The project's objective is to employ immersive visualizations to map the dynamic form of the Metaverse. This will be achieved by creating a representation of its network infrastructures, the multitude of communication and transportation networks that span between its digital & physical states, from : online social spaces, 3-D immersive worlds, geospatial worlds and the physical world.

infra|vergence is a research/project into how to map the scale & extents of the metaverse based on passively capturing network data flowing through this complex infrastructural nexus.

infra|vergence is also a project/research. By focusing on the divergent/convergent qualities of the metaverse, a visualization will emerge showing not only a quantitative representation of this network, but also an expression of its qualities.

This presentation will be illustrated by referring to other projects that have been created for the metaverse.

Key Concepts

We will begin by establishing a common definition of the METaverse to help avoid ambiguity and to determine the scope of this project.

metaverse : We define METaverse as the collective, consensual space created from the convergence of digitally enhanced physical reality and physically persistent virtual and online worlds. The METaverse is composed of the sum of all virtual worlds, augmented realities and network enabled services for communication, collaboration and location.

components of the metaverse

1. Virtual worlds : A virtual world is synchronous, persistent network of people (represented as avatars) interacting in a physically coherent spatial environment that is rendered by networked computers.
2. A user is considered INWORLD when he/she is active in a specific virtual world.
3. Metaverse Roadmap (Smart, Cascio & Jerry Paffendorf, 2007) : "the convergence of virtually enhanced physical reality and physically persistent virtual space." In fact, it is a fusion of both, while allowing users to experience it as either.
4. This last point is essential. "allowing users to experience it as either" implies that, whether INWORLD or not, one can be constantly engaged or co-present, with the metaverse, constantly in contact with it through social media or geospatial worlds. This hypothesis is essential to how we collect our data.
5. mirror worlds : informationally -enhanced "reflections" of the physical world, creating a service used for real world orientation and navigation, for example Google earth
6. augmented reality : exists through the use of technical interfaces, such as mobile computing devices, to enhance the external physical world by superposing location-aware information on top of our everyday perception of the world
7. all of these components of the metaverse overlap and converge to fabricate an immersive, albeit fragmented, experience for consensual users.

FRAMEWORK

The essential support structure of this project (its framework) is the technical infrastructure, the persistent data networks, and the social constructs emerging from them.

Due to the complexity of these divergent and convergent infrastructures, their simple classification transcends of any one of them. For example : information infrastructures (making possible global communication) are augmented by transportation infrastructures (enabling mobility) to compose dynamic urban environments; financial infrastructure are magnified by legal systems to define market economies; supply chains are brought into focus by energy infrastructures to determine the patterns of territorial occupation...

An infrastructure can be represented as a function of the quantity and quality of the data that circulates through it.

ACCELERATOR

In addition to infra|vergence's stated objective to Map the Metaverse, we are committed to carrying out research concerning metaverse ecosystems. These include addressing innovation in the design and building of immersive 3D environments and the unique media-forms it enables. But also, engaging a program of design research that specifically addresses the metaverse and its relationship to the discipline of ARCHITECTURE.

We call this program of Design Research SPATIAL INQUIRY, the independent research for the invention of new spatial/structural typologies. Our active participation with "vehicles of cumulative innovation" will help assure that architects meet "the challenges posed by contemporary society, thus translating those challenges into viable briefs and design tasks to serve to upgrade architectures' capacity to fulfill its societal function" within our "Networked Society".

The following project will describe how our control group, a participating community of metaverse residents, are organized.

Project : (REZ)ident

Infra|Vergence will focus on co-presence as one of the metaverse's singular qualities. The project's incipient stage is the development of its proprietary database. During metaREZmalaquais workshop (École Nationale Supérieure d'Architecture Paris-Malaquais, February 2011), an Inworld residence on the ARCHI21-World Island (in the virtual world of Second Life), residents generated this database. A multiplicity of projects concerning the spatial organization and sustainable development of the ARCHI21 project's collaborative, networked environments were developed passively, recording of their inworld activity (movement, collaboration, building...). This database will enable workshop participants to follow-up the experience with a project of cartography.

MAPPING

Generating the actual visualization of the metaverse, takes place via a process called MAPPING. infra|vergence proposes to map not only the scale & extents, but also the form&structure of the metaverse based on data intensive usages of this complex nexus of infrastructures. To achieve this, we rely on the HYPOTHESIS that a network infrastructure can be shown as a function of the data that circulates through it. Thus, by measuring network activity concerning specific metaverse related tasks, we can make this network and its infrastructure visible. Data will be captured from the network activity of a diverse community of metaverse users, the project's CONTROL GROUP. Information will be captured by observing simple, pre-defined activities (or gestures) that are inherent to each world.

The Data types are qualitative data, which asks, "What is the activity?" (building, logging in, holding meetings, chatting, shopping...); quantitative data, which inquires as to the intensity of any one activity (its duration, how many (people, objects, things...), how much...); and locational data, which asks, "Where is the activity taking place?" (physical world, virtual world, social network...).

Although the activities are not necessarily the same in each world, they are compatible and comparable. : For example, bodies are mobile in both physical and virtual worlds, and, while not entailing the same

act (ie, taking an airplane vs. teleportation) the results can produce comparable quantitative and qualitative data (distance, location, velocity...) attesting to the specific activity. The compilation of this data will serve to describe the services (protocols, debit, units of exchange, location...), physical, locational and technical qualities (connective matrix, location, technology...) and the geographical territory in which infrastructures' are deployed.

Project : (VIZ)ualisation

During the metaREZmalaquais workshop where residents were generating a multiplicity of projects, metaCARTOgraphy challenge to trace residents path and activity. Its goals were to capture these informations, a bracelet was distributed to each resident, containing a script to record residents' inworld activity and transmit the data to an online database. All the residents wearing scripted prothesis were passively recording and transmitting data about their presence, their location and their proximity to each other. The collected data is agregated in a databse hosted by Pachube, a web-based service built to manage the world's real-time data. The visualization of simple tasks or events through recorded data was developed using grasshopper, which is a graphical algorithm editor.

These visualizations were developped both with historical and live data streams. Based on historical data-sets recorded during the workshop to manipulate these data in an offline mode. Otherwise, using real-time data-streams to feed and stimulate pre-established visualization frameworks. The process mentioned above allowed us to build a bridge between three environments: the workshop's ARCHI21 island, the pachube's online database and grasshopper's algorithm editor. The output was generated in Rhinoceros's 3D modeling environment in which Grasshopper is tightly integrated.

VERGENCE

Although data is objective project parameter, a numerical value, its subsequent representation is subject to interpretation. We developed spatially immersive visualizations as our interpretive, representational tool. These visualizations will evolve from 2-dimensional graphic abstraction to interactive, tactile spatial immersion, by accruing informational, material and spatial dimensionality. These representations will be built into an immersive virtual environment whose physics, spatial coherence and topography will be designed to SIMULATE scale, distance, interactivity and modularity... Embedding visualizations into immersive environments is compatible to the process of data mapping (which is the creation of functions between distinct data models, for data integration).

Thus we strive to effectuate a direct correlation between the content (or data) and its representation (or mapping) : for example, when expressing the SCALE of the metaverse, an immersive visualization permits us to develop a 3D space whose size and navigation are a direct (not metaphoric) expression of its scale. This is due to the fact that immersive visualizations take place in a virtual environment with physical characteristics (physics, movement, temporality) similar to the physical world we inhabit.

It is not a question of mapping the totality of this infrastructure, but of determining their extents. : The physical, virtual and online worlds of the metaverse each possess an inherent logic that is divergent and convergent with one another. Therefore, the actual extents and limits of any one world of the metaverse are nebulous; the lines separating them are blurred by their dynamic co-dependence. Interpreting

this data will be accomplished by isolating specific states within each world and representing their points of vergence, revealing the tension between :

comparable states (or activities) in different worlds (ie, distance and velocity for comparing mobility in virtual and physical worlds); different states (or activities) in the same world; and,

simultaneous activities in more than one world (ie, interactively representing the same data-set in a virtual world and in an online visualization).

Project SCOPE

To avoid analogy, metaphor or abstraction when attempting to represent the scale, location, rhythms or textures of a complex, global network such as the metaverse infrastructure, we will be striving to create an expression of the metaverse that goes beyond merely mapping its quantitative data --striving to combine representation and sensation. In the context of the infra|vergence project, this is a process entitled : DESCRIPTION/ENCRYPTION

This expression is, in fact, a means of FRAMING the world in order to better see the metaverse. Framing is “a system of entities, postulates and rules that enables society to identify, perceive and label an emergent phenomenon from the seemingly infinite number of occurrences”. The Immersive Visualizations to be developed by infra|vergence allows us to frame the extents of the metaverse.

DESCRIPTION/ENCRYPTION as an creative tool We strive to development representations that express the sensation of inhabiting a data saturated metaverse. What are some of the omnipresent realities that are deeply embedded in our quotidian experience, beyond our perceptive capacities? If daily interaction with volumes of data and numerous messages is part of our new “data-subjectivity,” how can we represent this experience in new ways? How can immersive visualization express the ambiguity, the otherness, the multi- dimensionality of our experience, going beyond already familiar and “normalized” modernist techniques of montage, surrealism, abstraction, by formalizing the fundamentally new dimension of being “immersed in data?”

This expression will take the form of not only visualization graphics, but especially of IMMERSIVE VISUALIZATION They will permit the revelation of the dynamic, evolving form of communication and transportation infrastructures as they facilitate the simultaneous occupation of digital and physical worlds across three networked spaces.

Framing

Data visualization in 3D environments becomes a question of inventing legible objects and spaces that are capable of revealing the situations, places or things that compose the metaverse. 404-Window is an installation presented at the 404 Festival in Trieste, Italy in 2009. Its goal was to “open a window between virtual and physical worlds; it accomplished this through the fabricaiton of “real images from virtual worlds and virtual images from real worlds.”

Through the use of real-time montage from within a virtual world, the superposition of a real virtual landscape (Sizigia, Second Life) is framed by a Heads-up Display (HUD) that is also connected to a database embedded in that virtual world, and accessible at geographically located beacons.

404Window is both a machine fabricating a dynamic spatial composition from the convergence of image and movement, information and form, meaning and emergence, space and force; a device for reading and writing the essential organization of a world (physical and virtual); and, a dynamic representation capable of revealing these conditions through the fabrication of an Image-Space. In this context, data visualization in immersive spaces becomes a genuinely new cultural paradigm.

Dataflow

The framework of computation and network connectivity is organized according to a Dataflow graph containing nodes that produce data streams (inputs), nodes that transform data streams (programs, algorithms, APIs, libraries) and nodes that consume data streams (output). Dataflow as a model of information processing is based conceptually if not physically, on a graph of data flowing between operations. Dataflow promotes the data in the system as its main component. Systems conceived using the dataflow prototype start with an input and succeed by illustrating how that data is used and modified.

This enables real-time message handling, a procedure necessary for this project

The following related project description fills in some of the details of the dataflow machine employed by the infra|vergence project.

Work Process

For creating an immersive representation of the metaverse, infravergence will be harvesting historical and live data streams from networked sources, using them as raw material in a collaborative design environment. By measuring and comparing simple usage patterns inherent to each spatial typology, we can employ quantifiable and qualifiable data types. Data will be scraped from open source resources, open API's or publicly available sources to extract and interpret network semantics and I/O data. Generative algorithms will be used to aggregate data-sets for the creation of meaningful spatially immersive 3-dimensional visualizations.

We will use visualization techniques to model the metaverse infrastructure based on data exchanges resulting from a simple network activities by the infravergence community.

By capturing simple actions through the passive observation of the infravergence community, measuring its movement and location, online and inworld activity, we can qualify, quantify and localize activities in each world. By organizing the data according to forms, textures, scales, proportions and many other characteristics based on keyframes consisting of coincidental events capable of placing the metaverse's three worlds in tension. Visualizing these points of vergence in a spatially immersive visualization, composed of 2 and 3-dimensional, stable and unstable, passive and interactive representations, will allow us to represent and reveal the supporting infrastructure of the metaverse, thus mapping the scale, texture, intensity and context of this infrastructure. By accruing informational and spatial dimensionality, the

project will push its visualizations to evolve from objective abstraction towards spatial immersion. Visualizations will be created using interactive representations built into an immersive virtual environment whose physics, spatial coherence and topography will be designed to simulate the scale, interactivity and modularity of the hybrid infrastructure's form, location and intensity.

Project objectives

1. Create a representation of the metaverse, a map or visualization of its scale, limits and size that is both graphic and immersive, interactive and tactile.
 2. A program of design research
- - Research into visualization design : Develop knowledge concerning the coherence between the semantic and formal aspects of data visualization. How is the content or meaning of the data related to the formal qualities of its representation? (i.e. : using virtual worlds to represent information about the metaverse).
 - - Open Source Architecture : projects whose “production and critical, public, client (and) peer-related (reception) form part of the project itself, creating a feedback loop that can ground—or unmoor—a project’s intention and ultimately becomes part of it...” These projects “supersede architectures of static geometrical form with the introduction of dynamic and participatory processes, networks, and systems... distinguished by code over mass, relationships over compositions, networks over structures, adaptation over stasis.”

CURIOSITY AS AN ARTIST'S BRIEF

Rudi Knoops

In this paper I will discuss some techniques that I use as an artist to instill curiosity. The criteria for my 'discourse' are set out by Stephen Bann in his book "Ways around Modernism" wherein he formulates an "ambitious brief for the present-day artist in respect to curiosity".

I will elaborate on this brief with references to my own work, and show how a media-archeological mindset can be a source of inspiration for an artist.

The criteria for my 'discourse' are set out by Stephen Bann in his book "Ways around Modernism" wherein he formulates "a specific and ambitious brief for the present-day artist in respect to curiosity." [1]

I will here discuss some techniques that I use as an artist to instill curiosity, and elaborate on the three elements of Bann's brief:

1. that the practice in question should combine the process of experiment with the irreducible appeal of the singular object;
2. that the artist should seek to adopt, and of course to revise, historical precedents reminiscent of earlier conjunctures between art and science;
3. that our attention should be drawn to particular, appropriate types of locale for the work. [1]

The Brief - part 1

In a confrontation of present-day art practices with this brief, Bann refers to curiosity as a historical ricorso: the recurrent practice of retracing some of the older pathways with their ambiguous connection with art, science and technology.

For audiovisual media, this return to curiosity is advocated by different scholars in the field of media-archeology:

This anarchaeology of media is a collection of curiosities. [...] By curiosities, I mean finds from the rich history of seeing, hearing, and combining using technical means: things in which something sparks or glitters – their bioluminescence – and also points beyond the meaning or function of their immediate context of origin. It is in this sense that I refer to attractions, sensations, events, or phenomena that create a stir and draw our attention. [2]

Harking back to this ‘deep time of the media’ and uncovering undeveloped possibilities can be an important source of inspiration for contemporary art forms. A media-archeological mindset becomes a fertile context for serendipitous insights, a trigger for “fortuitous finds instead of searching in vain.” [2]

The link between curiosity and research methodologies used is obvious: as the fortuitous finds that shock you into the awareness of new possibilities are unquestionably also the most interesting finds, curiosity – in its general meaning of an inquisitive interest – is always part of any research approach. My own practice, characterized by a research through design approach, could thus easily be rephrased as research through curiosity, or research guided by curiosity. And "it is the by-products of experiment that will often prove to be the most important dividend, at least for the artist." [3]

The Brief – part 2

Adopting media-archeology as a methodology has already partly answered the second part of the brief. But I still have to elaborate here on the media-archeology based techniques I employ in my work as a media artist, namely re-injecting analogue elements into the highly digital apparatus that video has become. The technique of anamorphosis is one such form of mediation that I use in my work.

It is however not a pure analogue form of mediation, as I first use algorithms to ‘anamorph’ digital video materials, and secondly I implement, on the viewer’s side, mirrors that function as hardware mediators between the projected visuals and the viewer.

In fact it is a hybrid combination of exploiting the possibilities of the existing digital apparatus, and adding an analogue/hardware form of mediation using mirrors that questions the traditional audience-screen relationship.

ANAMORPHOSIS

Definition of Anamorphosis:

1. A distorted projection or drawing of anything, so made that when viewed from a particular point, or by reflection from a suitable mirror, it appears regular and properly proportioned ; a deformation. [4]

Anamorphosis is an optical curiosity that has a long history of being positioned on the intersection of the fields of science – architecture, optics – the magical and art. As an optical subterfuge anamorphosis is especially interesting because of its interfering with the laws of perspective: while asking the observer to view the distorted shapes from a determined point – thus enforcing a certain perspective upon the observer – anamorphosis at the same time shows the illusion of that perspective.

Exploiting this core characteristic of anamorphosis – the inherent possibility to impose perspectival limitations – touches the core of my PhD research wherein I explore how interventions on a number of parameters of the video apparatus can generate a sense of wonder and curiosity with the observer, in search of a contemporary iteration of the concept ‘cinema of attractions.’ [5] ‘Cinema of attractions’, not in its meaning of historical time indication in early cinema theory, but in its meaning of being an ever present undercurrent surging to the surface whenever the fascination for and the explicitation of the medium takes the lead.

Anamorphosis perfectly fits this picture of what a cinema of attractions can be, firstly by exposing the laws of perspective and thus focussing on the medium itself, but in second instance also by its many references to the realms of the phantasmagoria, the uncanny, the magical and the taboo.

Daniel Collins’ description of the observation of a single anamorphosis is of interest in this context

To observe anamorphic images, one must be an "eccentric observer", that is, an observer who is not only a bit "eccentric" in the usual sense of the term (i.e. "strange") but an observer who is willing to sacrifice a "centric" vantage point for the possibility of catching a glimpse of the "uncanny" from a position off-axis. [...] An eccentric observer is exactly the observer of the anamorphosis, an observer who literally "stands apart" and is self-aware of the process of seeing. [6]

In contrast to the traditional Albertian one-point perspective representation, that solicits an immobile stance from the spectator, an anamorphosis demands a dynamic act from the observer, an exploration of the 3D space wherein the anamorphosis is projected or displayed, in search of a favorable vantage point from where the warped 2D image coalesces into a coherent form.

One main type of anamorphosis is the group of catoptrical anamorphoses where special mirrors – cylinders, cones, pyramids, prisms – are used to reconstruct the distorted image. [7] In cylindrical anamorphoses a mirror in the form of a cylinder has to be used in order to view a reconstruction of the distorted image from a specific vantage point.

It is exactly the possibilities of cylindrical anamorphosis that I explored for the visual part of the media-installation DIORAMATIZED #02.

DIORAMATIZED #02

DIORAMATIZED #02 is an experimental design exploration in the framework my PhD research. I coined the word DIORAMATIZED because it refers on the one hand to the 19th century phenomenon of dioramas of which it transposes a few parameters into a contemporary interactive media formula: the modulation of light, the use of sound effects, the application of perspective, [8] the use of multiple moving images, or sometimes moving observers. On the other hand the word DIORAMATIZED carries some of the meaning of the word 'dramatized' as the multiple auditive and visual elements are presented in a very theatrical setting.

DECONSTRUCTION AND OPPOSING FORCES

The musical content of DIORAMATIZED #02 is the performance of Gregorian chants from four antiphonaries. For each of the antiphonaria the singers are filmed individually from top to toe against a black background. The video footage is being warped and displayed as separate visual elements. In the centre of each warped image is a cylindrical mirror. Only by looking at the mirror from a specific vantage point you will see the original recording dewarped correctly, the viewing angle being the key to 'decoding' the distorted image.

For the audio part of the installation, also each voice was recorded isolated. Each of the five visual layers has a corresponding sound layer, and the listening 'angle' coincides exactly with the angle of perception for the visual anamorphosis. But there is a difference built in that introduces friction between sound and vision.

From a distance, it is the sound emanating from the cylindrical construction that lures the observer to approach the installation. Upon discovery that next to sound, there are also images on display inside the contraption, the exploration of the manipulated layers of sound and vision can start.

The best position for perception of the sound layers is exactly in the centre of the installation, where the different sound layers merge into a 'surround' sound. The visual part of the installation works slightly different. Focusing on just one of the anamorphoses, it is perfectly possible to find a correct vantage point. Through the use of multiple anamorphoses however, and the specific circular setup, there is no ideal position to get a combined visual overview, and the search for good visual perspectives drives you away from the centre of the installation.

There is, in addition, the discrepancy between the size of the warped projections and the size of the dewarped reflections in the cylindrical mirrors. The warped projections function as points of attraction because of their sheer size and luminosity. When exploring the installation however, the dewarped cylindrical reflections may take over as main points of interest. As observer – an active viewer/listener – you make your own choice between these opposing forces of sound and vision.

The Brief – Part 3

The media-installation DIORAMATIZED #02 is an integral part of the exhibition 'Divine Sounds – Seven Centuries of Gregorian Chant Manuscripts in Flanders' at M – Museum Leuven from september 8 till november 27, 2011.

The centre of the exhibition is not only these manuscripts, but the audible music itself. Visitors can hear the music they are looking at, and listen to differences in style, form and performance practice in the installation DIORAMATIZED #02 by multimedia artist Rudi Knoops. Three top ensembles – Cappella Pratensis, Psallentes and Psallentes♀ – breathe new life into four antiphonaries from the eleventh, twelfth, seventeenth [...] and eighteenth centuries. The integration of an installation with historical heritage raises that heritage to a new level: that of contemporary art. It refreshes our collective memory and brings it up to date; the ancient traditional chants not only get a fresh coat of paint, but become an essential element of a new artwork. [9]

As visual concept for integrating the installation into the white exhibition space, I covered the top part of the installation in a mirroring sheet, and the reflecting light of spots draws a full circle around the installation, in balance with the light level allowed for the precious manuscripts on display. At the same time keeping the centre of the installation as dark as possible to guarantee the best visual quality of the images projected inside the contraption.

Second element of this lighting concept is an inverse application of anamorphosis, now utilizing pure light. On the inside of DIORAMATIZED #02 I use warped video projections and from specific vantage points you can see the video images reconstructed in the mirrored reflections. On the outside of DIORAMATIZED #02 however, I use lights that are reflected by the mirroring hull, throwing warped reflections on the floor that merge into one shimmering nimbus of light.

Third and final function of having this aura of light around the installation, is a reference to light being filtered through the stained-glass windows in a Gothic cathedral – which still is the ideal location for performing Gregorian chant.

Thus recreating part of the atmosphere of an "appropriate type [...] of locale for the work" comes close to an answer to the 3rd part of the brief of Stephen Bann.

Challenging the traditional audience-screen configuration

Through the use of anamorphosis, and especially through the multiple use of anamorphosis, I challenge the traditional audience-screen configuration. Instead of a viewer immobilized in an Albertian tradition of static one-point perspective representation, the observer becomes an active participant, who's full sensorium of vision, hearing, feeling, walking ... is called upon.

In this dynamic act of exploring the multiple images and sounds on offer in the audiovisual installation, the peripathetic observer becomes an active participant in the articulation of the projected – or (re-)presented – objects, and constructs his own perspective on the music performed.

This concept of the construction of vision through the dynamic act of the observer, comes close to an embodied phenomenological concept of perception. Mark Hansen positions the 'affective body' right in the centre of the perceptive act. In his neo-Bergsonian phenomenological concept of perception as an act of subtraction 'affectivity' is the sum of the "bodily modalities of tactility, proprioception, memory and duration." [10]

In DIORAMATIZED #02 it is the friction between sound and image that stimulates curiosity. Curiosity as the driving force, the trigger for bodily activity, the formative power in a dynamic and personal sensory experience.

As observer you engage with the installation, aware that what you see and hear is the result of a specific media configuration, but at the same time you are at risk to lose yourself in a fascination for the mirrored world created in this Wunderkammer of sorts.

In contrast to Collins' description of the 'eccentric observer' of one single anamorphosis, the viewer/listener explores the innards of DIORAMATIZED #02 – with its display of multiple anamorphoses – from within the installation. Instead of being an 'eccentric observer' in the literal sense, the viewer/listener immerses himself in a multi-perspective experience that challenges his curiosity and invites to explore these multiple perspectives.

CROSSING OVER: ART, DIGITAL PERFORMANCE AND PRACTICE-BASED PEDAGOGY

Rachelle Viader Knowles, Wade Sakundiak & Kathleen Irwin

Crossing Over Web interface, designed by Wade Sakundiak

What we do, how we choose to act and interact and ‘spect-act’, perform and play and replay, will differ for each of us, at each moment, and for many political and personal reasons. One thing only is certain; we will be faced with such choices in ‘real life’ and in any number of digital or virtual performative spaces as well – even in our own imagination and dreams; in the spaces of our own desires (Goodman 294).

Crossing Over (<http://www2.uregina.ca/crossingover>) is an ongoing project devised by Kathleen Irwin and Rachelle Viader Knowles, connecting students from the Faculty of Fine Arts at the University of Regina with other students around the world. The workshop is a pedagogical art / performance / video project that investigates and engages the terms of cosmopolitanism as a way to constitute meaningful social networks by exchanging virtual performances -- and suitcases -- over the internet. The question that the project asks, about our responsibilities to strangers, is critical in light of global mobility, the blurring of borders and the instantaneous exchange of information that crossing over points, both real and virtual, represent. During the workshop, these ideas are explored using readings from Kwame Anthony Appiah’s *Cosmopolitanism: Ethics in a World of Strangers* (2006).

A visit to the website shows how the exercise unfolded. Student players in both locations were required to fill in an online immigration form in order to construct a real or imaginary identity. Each packed a “digital suitcase” with personal belongings (images, sound fragments, text, etc.) to equip them in their new life and to transport across a virtual border (or in this case, to upload to a baggage conveyor belt on the website). With the click of a mouse, students in the arrival country claimed suitcases from the conveyor belt and opened them, thereby making the contents available for public scrutiny. Following this

point of entry, emigrants were no longer in control of their destinies, as the recipient of the luggage was left to sort out its contents and plot a putative future based on knowledge of the current socio-political contingencies in the arrival country. The process attempted to replicate the crossing of international borders for immigration, emigration, or asylum seeking and suggested the tensions that occur when the fragments or “facts” of one’s existence are publicly displayed and possibly misinterpreted. Through the process, students were asked to consider their own country’s migration and refugee policies, their own response when confronted with “otherness,” and the problems associated with communicating the signifiers of one’s identity in a public forum in ways that may deleteriously affect outcomes.

The Crossing Over workshop offered during the 2011 ISEA conference is the second iteration of the project, connecting students from the Visual Communications Design program at Sabanci University in Istanbul with students from Visual Arts, Film and Theatre Design at the University of Regina in central Canada. The larger context is the city of Istanbul, itself a gateway or crossing over point between east and west, a cultural and creative nexus between diverse people and practices in art, philosophy, science and technology. The first iteration of the project/workshop was carried out in 2008 between students in Fine Arts in Regina and students at the School of Art in Utrecht in the Netherlands. The project was conceived during Knowles and Irwin’s tenure as University of Regina Teaching and Learning Scholars, a program designed to challenge university faculty to move beyond traditional divisions between research, teaching and service and towards more multilayered, interconnected, and interactive conceptualizations of faculty work. This project develops out of a teaching methodology, shared by Knowles and Irwin. It combines studio practice and theoretical investigation and understands that such interconnectivities encourage students to think broadly, deeply and creatively and to explore the possibilities that exist where one or more disciplines and cultures intersect or collide. Crossing Over concentrates on processes, theories and paradigms for innovative practice-based research that traverses distance, time, language and disciplines. It provides a framework for collaboration that engages students in a creative exchange of “identities” within a post-colonial context. This second iteration of the Crossing Over website was designed and built by Wade Sakundiak from the University of Regina Centre for Teaching and Learning, utilizing several technologies to realize the project goals. The site is built using ExpressionEngine, a CMS (Content Management System) used to facilitate user interaction with the database which holds each participants responses to the questions asked during the ‘immigration’ process. Building upon this base, Javascript and HTML 5 provide the frontend functionality and animation throughout the site, lending an element of authenticity as visitors explore participant profiles.

In the absence of avatars and mythic scenarios, as an interactive web-based activity, Crossing Over operates more as an international parlor game, played out in real time and at street level. The rules of engagement ask players to perform identities and respond in kind to their international teammates. In so doing, participants blur the distinction between performance and social networking. Players are asked to question the representational armature of narrative and character that conventional performance operates within and to see digital performance as a fluid, and evolving field - an intertextually coordinated, multiply located discursive field of operation.

The project is part of Knowles and Irwin’s ongoing research investigating changing modalities of performance that asks whether the Internet has any distinct, useful or unique characteristics that offers performance anything other than merely another means of distribution. In 1991, Brenda Laurel wrote that media opens new possibilities for experience and speculated that virtual reality would, in due course, contain more functions than databases, games and networks (Laurel 194-95). Less than two decades later, much has changed and such a statement is reductively self-evident. Indeed, while the internet today provides a multitude of opportunities for rich social interaction and ‘stealth’ learning outcomes,

the opposite is also undeniably true. It offers countless portals and opportunities for considering options and confronting difference, not all of which are congruent with the ethics of cosmopolitanism. Yet the consideration of these ideas, framed within practice-based research, offers a productive, albeit playful, exercise in implementing ethical strategies and rehearsing life skills necessary to function in an interconnected global community. The students who participate in Crossing Over are quick to recognize the limits of the paradigm we propose but are prepared to struggle with the ethical question Appiah posits – “how and to what degree are we responsible for others and how far do we extend kindnesses to strangers?” – as well as the related questions we proposed: “how do these questions relate to art making and new modes of dissemination and performance?”

HYPERPRESENCE: TELEPRESENCE VIA QUANTUM CINEMA

Osman Koc

Today's technology enables us to impact and observe places by different telepresence methods. Telepresence methods have been implicated into various applications such as robotics, communication and art. The paper aims to introduce a new telepresence application for cinema, which creates a customized narrative by using the user's bio data.

HyperPresence, Osman Koç and Fethi Can Tüzel, 2010

As technology enables not only processing data but also transmitting them, we started hearing and using "tele" as a prefix in our daily lives. It has been attached to many different words such as telecommunication, television, teletext etc. After these reinterpretations of actions occurred with the advancements in technology and industry, another 'tele' prefixed word has been created, namely telepresence. Scott Fisher, one of the pioneers of the concept, explains "a technology which would allow remotely situated operators to receive enough sensory feedback to feel like they are really at a remote location and are able to do different kinds of tasks."

Telepresence encapsulates several subsections in industry like tele-robotics, video conferencing and so on. Each of these subsections approach to the aspect of stimulation of the remote location and sensory feedback from different angles. In tele-robotics the sensory feedback is mechanical, but the remote location can be virtual (haptics) or a robotic system (bilateral teleoperation). In both approaches the tactile sensation is crucial. The main purpose for tele-robotic applications is the remote location being haz-

ardous or inaccessible. Telepresence robots are also becoming popular, as they allow visual and auditory transparency, as well as controlling the motion of the robot in physical space. In video conferencing the immersion is enhanced by eye-contact and having the same interior design for the physical spaces at both sides.

There has been different ways of telepresence techniques experimented for artistic purposes. Kirk Woolford's work approaches to this concept by using the flow of air as a medium of telepresence. Two people wearing belts made of fans are present in two separate rooms. The cameras installed to the ceilings enable the users to be in the same room virtually. The way to sense each other occurs through the wind one creates as it passes by the other, which is created artificially by the fans.

In order to extend the boundaries of the telepresence concept, it might be illuminating to think about different media in which the user is immersed consciously or unconsciously, but does not have an active role. Edward Packard's "Choose your own adventure" book series offer an example to this argument. In the books, the user is immersed by the scenario of the books, while having the opportunity to initiate on some choices. For example the reader can decide whether to go out by the door, or escape from the window, by jumping to the corresponding page, which gives the reader the liberty to customize the narrative of the scenario. As the narration is customized, the reader gains an active role, therefore, even though it does not accommodate any technological infrastructure, Edward Packard's concept can be considered as telepresence also.

This article aims to introduce a new way of telepresence, through an interactive art installation called "HyperPresence" implemented in collaboration with Fethi Can Tüzel in 2010. In order to delve into the subtext of the project, the telepresence concept is fragmented as remote location and stimuli, which will be expounded in detail in the following sections.

REMOTE LOCATION

Remote location is the part of the system which is observed and manipulated. Depending on the system, the observing medium can be visual, audial or mechanical. In order to sustain immersion, it is compulsory for the remote location to provide transparent sensation to the user. In systems where the remote location is a physical space, immersion becomes dependent on the quality of the data, which is provided by the sensors. For example, if the user is supplied with the visual data from the location, and the quality of the image is inadequate, the user becomes aware that the image is not real, but merely a representation of the reality. Apart from the quality of the data, in systems with multiple sensory feedback mechanisms, the delay and synchronization also becomes pivotal in order to provide transparency. Immersion with virtual spaces is more complicated to achieve. Human cognition distinguishes real and virtual depending on the experience based reality perception. The virtual reality environments fail to mimic physical spaces, thus the immersion wanes. As the action-reaction relation continues, the conscious immersion starts to build. Virtual environments are built on mathematical models. We can consider reality as an n -dimensional entity (n being a positive infinite number), but the performance of the affordable technologies allow realizing the reality to some extent in order to sustain the real-time specifications of the system. Until the model based realizations reach, maybe not to the n -dimensional reality, but up to the human perception limit, virtual environments will always be distinguishable regardless if they are visual, aural or mechanical.

Cinema can be considered as a midway between physical reality and virtual reality, as it seems real, but the context and the time may not be. Thus, it represents a reality which does not originate from any particular bit of the real world, or as Jean Baudrillard names it “hyperreal”. In a cinematic experience, the audience attests the juxtaposed images which might construct a reality effect, albeit the fact that neither the context nor the time of the film are necessarily derived from reality. But the perception of quasi-real images is sufficient for the audience to be submerged in the experience unconsciously; hence constituting a counter-example to the physical and virtual remote locations, where the user’s consciousness tries to disrupt the immersion. This immersion into cinema is called as “the suspension of disbelief.” Thus, this concept can be exploited for the sake of telepresence, as the audience already evolves an immersion unconsciously. To close the sensing-acting loop, this unconscious state can be exploited as well, which will be elaborated deeper in the stimulation part.

In order to sustain and enhance the suspension of disbelief or the illusion of reality, the perception of the audience should be considered. Cinematic experience is subjective. Thus, the usage of some filming techniques causes different effects on the audience. First person point of view anthropomorphizes the observance, hence enhancing the immersion, as the user is not just an observer in the represented hyperreal space, but it observes as a passive character inside the actor. The technique can also be augmented by adding some eye-blinking mask to the video.

Other than visual technique preferences, the soundscape of the film also affects the immersion. As explained by Denis Pegge, the audial elements are ingrained depending on the audience’s experiences. The sound of an object in the video may be different than what the audience would have expected, which cracks the illusion. Another audial element of the video would be speech. Speech would diminish the effect of the video by attracting some attention to the context of the speech, which is even worse for non-native audiences, as a result of the subtitle texts.

Lev Manovich denotes, emergence of the new media caused paradigm shifts, the constants are changing into variables in operational relationships. With these new perspectives in media, it is inevitable for any medium to stay untouched, which is also the case for cinema. Interactive cinema enables the audience to participate in the film by different ways. “Kinoautomat” is considered to be one of the first examples of interactive cinema by Raduz Cincera screened first at 1967, where at nine instants the movie stops, and an operator asks the audience to choose between two different possible scenes for the movie to continue onwards, by virtue of which the audience is authorized for deciding upon the progression of the narrative.

Apart from the motion capture based cinema, video games are also considered as interactive video, as they use computer as an interface to act between the series of video sequences. As the interaction with the medium closes the action-reaction loop, and users’ perception adapts to the visual medium, the immersion is cultivated, which leads to the feeling of telepresence. As aforementioned, cinema is hyperreal; ergo the telepresence with a hyperreal medium creates the “hyperpresence” concept, which also originates the name of the installation.

In examples of interactive cinema, where user is augmented with the ability to manipulate the narrative, multiple user based interaction might reduce the quality of personal experience by diminishing the feeling of participation as the outcomes of the interaction differs from personal responses. Considering that telepresence is a singular entity, the presentation of the work has been chosen to be a one-person experience.

The concept of interactive cinema conceived several different related concepts like quantum cinema which is originated by Peter Wiebel. The concept of quantum cinema, as the name implies, arises from quantum theory. Heisenberg's uncertainty principle denotes the trade-off between the measurement accuracy of position and momentum of an electron at an instant, which means the observance, manipulates the subject of the experiment, therefore the real data is uncertain. Another quantum theorist, Richard Feynman, has focused more on to the initial value problem of a system, where the system should not be considered as a whole, but as transitions between several different states, which all have different initial values. In a cinematic context, these concepts can be interpreted as the manipulation of the film as a result of its observance, and the film having different possible paths which evolve from different initial states.

The HyperPresence project exemplifies the aforementioned "quantum cinema" concept. The film used in the project is montaged in a non-linear way time-wise, which is linearized by the software depending on the responses of the user and the diachronical state of the film. The film starts from a single part which evolves to different narratives and endings as it is observed, and each inversion creates different possible films customized by the user. The decision points of the film are predefined; therefore finite numbers of possible films are present.

Without elaborating deeper about the technology fetish in interactive art in order to maintain the focus of the paper, it should be pointed out that the subject matter should also not be neglected. The theme of the film is based on an incubus dream that most people could have experienced or at least familiar with in their lives. As it has been explained before, the film is shot from the first person point of view, with eye-blink masks in order to enhance immersion. The method for harvesting the users' responses will be discussed in detail in the next part.

STIMULATION

Interaction is more than the machine obeying to the user; it is also the experience that the user lives. User interaction can be both conscious and unconscious depending on the type of interface and briefing about the experience. The interface can be a physical controller with some sort of form factor, or transparent like a camera based interface; but in both cases if the user is informed about the interaction, it will restrict the interaction as it leads the user to investigate the mapping between the actions and the responses, and eventually loses its playfulness and become just a tool. One stance against this may be creating a system with more organic responses in which the interacted medium does not always give the same responses, when given the same set of inputs. This would probably create a similar experience without satisfying the user's curiosity as a result of the stochastic responses of the system. On the other hand, what if the user is not aware of the interaction? The interaction interface and the obligation to interact consume some of the user's attention, which diminishes the effect of the experience. As a result unconscious interaction enables the user to get immersed in the experience without feeling obligated to interact. Unconscious interaction is like improvisation, where the line between user's cognition and intuition fade. In order to enhance the instinctiveness of the responses, biosensors should be considered as a medium of interface. The beauty of the usage of bio data for interaction is that, it anthropomorphizes the overall synthesized being, consisting of the body and the machine. Therefore bio data can be used to sustain and observe the effectiveness of the designed experience.

The roots of using bio data for non-medical purposes go back to lie-detectors, where it is assumed that the body doesn't lie. Bio data is specific to the source, which results in having a unique experience for

each user. Even as a result of inadequacies of the platform, the outputted bio data is the same, the resulting effect on the user is always unique, as Leibniz's identity of indiscernibles principle.

Cognitive sciences have developed thorough interpretations of bio data, which resolves to the user's emotions. Therefore, bio data is highly intimate and should be handled with delicacy by the designer. As the bio data is not fully governed by the user, unpermitted public exposition of this data would be considered unethical. As bio data represents the true self, it has been used for several different non-medical purposes. The fingerprint or retina scanners and camera based face recognition software provide advanced security systems which prevent the possibility of hacked or forgotten passwords. Marcel Van Der Drift exemplifies the misuse of bio data in "A Future Love Story", where the interpretation of bio data creates a positive feedback in the formation of user's moods, as the user becomes more depressed by gadgets interpreting the state of the user as depressed and the user finds salvation in technological homicide.

More artistic usages of bio data have been present in several media due to the new meanings they represent. DNA portraits offer an unusual way of representing the uniqueness of an individual. Christian Nold's experiment used skin responses of the user's in order to create an emotional map of a city. One of my previous artworks "Living Istanbul" examines the relationship between the sounds of a city and the heart rates, or the rhythm, of the dwellers. The installation uses the heart rates of the audience in order to recreate the different soundscapes of Istanbul.

The downside of biosensors is that, the user can be affected from any previous situation, which creates the user's initial state. Furthermore, during the experience the user can be haunted by unprecedented concerns which also lower the quality of the experience. In order to overcome this problem, the norm of the user is calculated before the first decision point of the film, and had been used as a reference to measure the deviation of the users' responses.

The HyperPresence project uses an electroencephalogram (EEG), for measuring the brainwaves to interact with the aforementioned quantum cinema setup, as it offers a fast representation of the arousal state of the user. It measures the amount of activity of the brain by the alpha and beta waves, the data is interpreted as the user's state being relaxed, tranquil or alert and excited, which is used to alter the narrative of the film.

CONCLUSION

In order to present an overview of the HyperPresence project, remote location and stimulation parts have been discussed separately. Different media and concepts have been investigated regarding the immersion of the user. Motion capture film has been chosen as a remote location medium, in order to benefit the predisposition of the users' suspension of disbelief.

As it has been stated before, the conscious interaction creates an obligation which diminishes the quality of the designed experience. The non-initiative state that the user enters as a cinema audience inspires the usage of biosensors as the stimulation interface. Bio data is not fully governed by the user, with the state of the user in mind, the true responses of the user have been tried to obtain in order to differ the experience from a game and anthropomorphize the overall structure which results in a more organic relation.

The user experiences a film that revolves around the theme of incubus, shot in first person point of view, wearing an EEG sensor without any further information about the forthcoming experience. Furthermore, the whole interaction process is explained at the end of the film as a classic grand finale in order to keep the user unaffected about the technological infrastructure of the setup. It is expected from the user to realize the transformation from an individual audience to the protagonist of the film, which fulfills the telepresence concept.

PERFORMER VS ELECTRONICS: PERFORMING MUSIC FOR INSTRUMENT AND ELECTRONICS

PANAYIOTIS KOKORAS

This paper investigates the challenges which face a performer when he/she has to practise a composition for instrument and electronics at home alone and then perform it in a concert hall. Analysis of a survey of performers identified an incapability of playing a work with electronics. In the second part of the paper, I propose a paradigm for performance material that could provide the necessary information for the performer.

1. Introduction

More and more performers today are asked to perform compositions for instrument plus electronics. Are they ready to do so? What should a performer know in order to be able to accomplish such a project, and what help should the composer provide? How far can a performer go and how much can a composer ask? A great deal of knowledge is required, and the problem looks initially to be very far from what a performer usually knows. [1]

2. The Survey

At the beginning of this research study, professional performers of new music who were under forty years of age were contacted by email and asked to complete a simple questionnaire. The questionnaire described a scenario in which a performer receives performance material in order to practise a piece for solo instrument and electronics at home alone, and then perform it in public. Questions were asked:

1. about their level in music technology and sound engineering (novice, intermediate or expert),
2. about the equipment they owned (laptop computer, external sound card, speakers, and microphone),
3. about their interest and their desire to programme a work with electronics and finally,
4. whether they had any experience of playing such a work and, if so, what their most recent experience was.

Analysis of the survey revealed a mixture of high scores on the practical questions and at the same time a lack of ability to play a work with electronics. Question four was intended for those respondents who answered 'yes.' In brief, starting with the responses to question three, the selected participants were positive about studying and programming a piece including electronics. Also, 100% of the respondents answered question two by saying that they owned three of the four listed items of equipment. The most disappointing result came from question one: 86% of the participants described their level in music technology and sound engineering as 'novice' and the rest described themselves as 'intermediate'. These findings result in two conclusions. On the one hand, their education had not offered them modules on music technology and sound engineering. On the other hand, the performance material which they received from composers had not helped them sufficiently to enable them to go through with a piece. These two major issues raised from the survey will be discussed in the following paragraphs.

3. Performance notes as a protocol

First, I shall take as a case study four works of my own for one instrument and electronics. These works are *Slide* for guitar and electronics, *Shatter Cone* for violin and electronics, *West Pole* for piano and electronics, and *Jet* for recorder and electronics. [4] I shall propose a paradigm for the performance material that will provide sufficient information to enable a performer to practise and play a piece alone. This could work as a reference for a composer and as a guide for the performer to know what to expect and how to prepare a work for performance.

The four works listed above were written for one amplified instrument and electronics. The electronic part combines fixed electronics in the form of pre-recorded electroacoustic sounds and live electronics that come to life as a response to the performed part. The performance material includes:

- the score,
- the performance notes,
- a stereo track of the fixed electronics,
- a mono click track audio file,
- a folder with the extra plugins, and
- a folder with the preset settings of the plugins.

Finally, it is useful to provide a full version of the piece as a reference. The performance notes, apart from the instrument's performance and notational instructions, should provide information about the four elements explained in the following paragraphs.

3.1 LIVE ELECTRONICS

The Live Electronics section should provide instructions on the main application needed and how to use its session for the piece, which are the hot keys, and what are their functions. Moreover, there should be displayed screenshots of the plugins to make sure that the settings of the vst effects are loaded properly in the first instance. This section should also explain the way that the live electronics is going to be notated on the score. It is of vital importance that the composer should provide a sort of notation for the live processing. The performer should, by reading the score, be able to anticipate the when, what and how of the way in which the live electronics contributes to the piece. Finally, to make sure that the real time processing produces the expected result, some sound samples should be provided with each of the effects applied separately. Thus, it would be easy to compare the example sound with the performer's sound and to figure out possible incompatibilities. [2]

3.2 HARDWARE SET UP

To study such a piece, the performer should be equipped with some hardware, primarily consisting of: 1) a laptop, 2) a sound card (at least three outputs, one input), 3) a microphone, and 4) a pair of speakers. A signal diagram is useful to show the way the signal is traveling through the devices and the software. The stage layout should clearly show the position of the speakers, the performer and the microphone, as well as the way to connect the devices. In addition, information should be provided about the Audio Preferences menu of the software used and how to make sure that it has the right setting.

3.3 AMPLIFICATION

Once the software and the hardware are up and running, it is time to give some emphasis to the amplification of the instrument. The microphone should be placed close to the instrument. According to the composition's needs, it is recommended to have the microphone placed on an adjustable stand so as to be able to control which part of the instrument will be closest to the microphone. In addition, it should be made clear that the idea of the amplification many times is not just to make the sound louder but to create a supernatural sound which results in the loss of the neutrality of the classic known instrumental sound.

3.4 FIXED ELECTRONICS

The notation of the fixed electronics (or taped part of the composition) is important because the musician should always be able to follow it and be in sync with it. It should be placed in a form of sonogram staff below the live electronics staff line. The sonogram works as a visual representation of the tape part to help the performer to follow it accurately. The sonogram can be enhanced by the composer or the performer with extra shapes, words and rhythmic motives. At the left top corner of every staff, the time of the pre-recorded material is displayed. In the fixed electronics sections, there is also the click track which is useful not only during the practice but also for the concert performance. It should be appropriately arranged according to the tempo and time signature changes of the piece. Another issue which should be clarified in the performance material is the distinction between the rehearsal and concert situation. In the concert, the click track should be routed to the headphones only. In the rehearsal, the session should be flexible enough to start at any point. [5]

4. Conclusion

All the above described information will considerably increase the possibilities of a performer playing a piece with electronics successfully and repeatedly. It remains in the hands of the educational institutions to include it in their courses or improve their curriculums with opportunities to enable students to acquire the necessary knowledge to be able to carry out such projects. Music conservatory performance students should be able to follow classes with the focus on the performance of electronic music, and should have close collaboration opportunities with fellow composers, and the inclusion of compositions for instrument and electronics should be encouraged by teachers and included in the examinations concert programmes. IDENTIFYING PLACE AND PLACING IDENTITY IN TRANSNATIONAL TRANSMEDIA: A CASE STUDY OF TWO CONVERGENT MEDIA PROJECTS

Julian Konczak

Two case studies currently in development will be examined from a producers point of view while focusing on targeting new audiences, The two projects – TELENESIA and ANTIGONE INTERACTIVE both employ different toolsets that relate to the location and preferences of the target audiences.

"Telenesia/Antigone Interactive"

"A Transmedia production will develop storytelling across multiple forms of media in order to have different entry points into the story." [1]

The key point within this terminology being the idea of working *across* platforms as distinct from other models of digital storytelling such as "remediation" and "crossmedia" where content is replicated across platforms.

TELENESIA is a fictional place and alludes to a distant and inaccessible "no place" and resting on the idea of a place that exists beyond and outside of the increasingly throttling networked communication. Conceiving a physical location that is post- network and by inference suggesting a post- apocalyptic time zone developed out of a research edition of hidrazone.com and was used as a overarching terminology to describe the process of increasing fracture of audience experience as the communication networks get more pervasive. Hence, a range of digital media tools and working practices were brought together under an umbrella term – computational video, VJ sampling, glitch to name a few.

TELENESIA evolved into art based project in that the principle outlet for the work is an installation within an art gallery, however, in engaging with the key concerns of the work – fragmentation and atomization of post network communication – there were clearly opportunities within a multi-platform setting.

The core of the work draws on two key influences. Firstly, the occult power of the moving image is fictionalised in Theodore Roszak's *Flicker*, a pacey novel that follows protagonist Jonathan Gates. The narrative revolves around an academic researcher who penetrates a shadowy religious order responsible for embedding subliminal images into Hollywood - later to be forcibly marooned on a Pacific island with a decaying film archive. In many ways the background of the novel reflects an enduring 20th fascination linking occultism and media developed by figures such as William Burrough's *Cut-ups*, Bryon Gysin's *Dreamachine*, Kenneth Angers *Magick Lantern Cycle* and work by the English filmmaker Derek Jarman.

The other strand being explored in the work is the hardware hacking and glitch cultures that in turn are driven by what is often described as a post-modern deregulation of narrative, scratch video and VJ culture. The aesthetic intention is to attempt move on from post-modern nihilism where the destruction of image is an end in itself and to use these atoms of destruction in a novel fictional edifice.

Beyond the gallery, TELENESIA expands across ephemeral networks allowing the exhibition slot to use platforms as both publicity and marketing opportunity as well as providing a legacy in the form of documentation and video. The installation itself is built on "physical computing" sculptures – boxes that allow the visitor to the gallery to access and play with a database of short video clips using analog controls i.e. dials and knobs and while there was no intention to replicate this experience on-line, elements of the narrative have been extended into the internet.

The initial building block of the project was the 1-minute video that would emulate and draw in some of key tropes and practitioners of experimental moving image. These short films have been posted into a video blog and exhibited at international film festivals prior to venue and funding confirmation of the show tour. The project has been in development over a number of years and initially the look and feel of the video pieces was developed as a VJ set that used digital tools according to an "analog rule set" i.e. using image effects in line with film optical printing. An underlying impulse before devising this set (which featured with a vocal sampling group) was to move away from the hegemony of hard edge graphics and explosive eye candy of mainstream VJ culture – the VJ community appears to be hungry for material so the source clips have been released under a CC license and distributed via torrents thus creating an on-line participatory mode to compliment the installation.

ANTIGONE INTERACTIVE explores the relationships between physical location and narrative in a parallel and complimentary manner. The focus of this project is to tell personal stories of migration and political conflict – accommodating films created by experienced filmmakers exploring the hidden side of personal family history. By focusing on the personal over the political it entails challenging of the inherent artificial nature of political boundaries and the de-humanizing effect of the nation-state.

The genesis of the project grew from previous projects by the producers that had used a global interface to allow the audience to access video content reflecting stories and places from around the planet.

In developing the work within the confines of transmedia the producers use the borderless map as a starting point, borders become apparent as users drill down into content. This reflects the restrictions of movement across the surface of the planet that is the starting point for the narrative threads. To this

end the Google maps API with its extensive capabilities for overlaying geopolitical information and location markers was chosen as the key interface device.

Common to much of material created for internet consumption, work tends to be molded into short form productions such as the website, in designing the narrative structure of the project it, the challenge was to tell rich and complex stories while maintaining an offering that could be consumed in bite sized chunks. The work uses an episodic structure that enables a longer form story to be communicated while only experiencing a 4-minute section at any one time.

The interface enables the audience to access the video segments using a variety of menu options: a tagged map using Googlemaps API, a gallery of thumbnails and a video player that allows the clips to be watched as a long form video more akin to watching television, thus the user can calibrate their own experience in terms of levels of interactivity.

In terms of the viewing experience the tablet/ipad was the optimal distribution device that was chosen for a number of reasons – that the viewing environment could to some extent be predicted and the strength of the quality of video playback. At early stages of development, the creation of an app was considered has the potential to provide consistent rich media experiences, however, the limitations over distribution, extensibility issues and the fact that user base would be necessarily limited precludes this option.

Drawing together the two projects it can be noted that they exist in almost opposition to one another TELENESIA is a fiction that attempts to move audience in space and time, while ANTIGONE INTERACTIVE is underscored by accurate sense of personal experience. Whilst elements of their transmedia existence may bear some resemblance in that they use short video within a web based interface and such like, they are operating at different ends of the spectrum TELENESIA challenges the audience to immerse themselves into an escapist fiction while ANTIGONE INTERACTIVE intends to awake a political dimension within the user.

MICRO-MOCAP

SUSAN KOZEL

Motion capture performances used to be equipment heavy, fraught with calibration problems, and only for a privileged few. How have things changed? Developments in tracing, capturing, archiving, and sharing motion (including the Kinect) suggest mocap might play a different role in our daily lives. Further, there may be scope for synaesthetic translations or transmedia applications.

Micro-Mocap

Literature at the turn of the 19th century was described by Jacques Rancière as: “the new writing made up of sensory micro-events, that new privilege of the minute, of the instantaneous and the discontinuous.” [1] Developments in tracing, capturing, archiving, and sharing motion at the turn of the recent century suggest that tiny, motion captured gestures might be another way of writing the minute, the instantaneous, and the discontinuous. Further, there may be scope for synaesthetic translations or transmedia applications. This short paper briefly describes a journey through experiments with motion capture, ending with speculations regarding new developments and the role for captured motion in our mediated lives.

THEN (DISSOLVING INTO PARTICLES)

Looking back at much of the motion capture experimentation I have done since the 1990s I see fragments of bodies: points, lines, particle systems. Movement billowing outwards, then being condensed to a single point. Dancers walking through each other’s data points as though wandering through constellations, or using their feet to create strokes like calligraphy. Creating basic data bodies out of Bezier curves, that twitched, bent back on themselves, or lost their proprioceptive maps only to reform with a leap and a stretch. [2] Endless fun, if you ignored the nightmare of calibrating these heavy optical or magnetic systems. We left small dark studios at the end of the day, blinking in the light, feeling imaginary markers on our bodies.

Experimenting as a dancer for many years, using whatever system I could get my hands on, my philosophical and aesthetic questions returned repeatedly to the sense of the data as an “other.” Not a mirror of my and others’ movements, but the sense of dancing with an other that challenged my own corporeal and ethical boundaries. It is possible to say that these experiments always somehow dissolved the body without losing its materiality: true to Deleuze’s understanding of Spinoza, bodies were composed of speeds and slownesses, combined with the ability to affect other bodies and be affected by them. [3]

NOW (TURNING THE PRACTICE INSIDE OUT)

Now the mundane beckons: less spectacle, less calibration, less performing in theatre spaces or secluded labs, and more the idea of capturing affect and motion in daily life. A question arises: can mocap,

that digital system most able to capture external form and virtuosity, be used to capture liminal or ambiguous internal states? This is part of a larger project aiming to explore Immanent Aesthetics in order to understand how our new technological devices may be able to foster internality, quietude, intuition, and depth – and social choreographies. [4]

Micro-Mocap is an experiment in accumulating a personal vocabulary of nothing movements, or little kinaesthetic snippets. Perhaps it is like a DIY Motion Bank without performative aspirations. [5] But can motion, once it is captured, really be non-performative?

The micro-movements of performing life are those moments where dance intervenes, where gestures become slightly more than pragmatic but may express very little. Jean Luc Nancy's reflections on sleep as the "formation of an interiority" where we cannot distinguish ourselves from what is not ourselves are strangely relevant. [6] I am my tiny gesture. And I am my grand gestures. I reflect the gestures of those around me to the extent that capturing motion is not about my movement at all, but movement as patterns of circulation and exchange.

So when I play with the ubiquitous Xbox Kinect, improvising a daily narrative of nothing movements, or micro movements, am I closer or farther from understanding how I move or inhabit the world? For now the gestures are not recorded: and in itself this reminds me of the ephemeral quality of live performance, back before we had to become documentation obsessed and a dance took place and disappeared. If I decide to save these motions (to capture and preserve, rather than capture and release) giving these to others will be like the strange intimacy of sharing of a blank text message. Its blankness is often thought of as a stroke: so intimate that nothing needs to be said in it.

AND (VENTURING INTO THE DOMAINS OF SYNAESTHESIA AND TRANSMEDIA)

As the liminal states of corporeality are explored through motion capture with the Kinect it is clear that the question of what is sensed (the input) is relevant, but it is more necessary to question what form the output takes because the Kinect is not designed to hold on to data. We have to decide what becomes of our motions, what happens to them and who receives them, in what form.

Marcus Ghaly, animator and interaction designer based at Malmö University in Sweden, recently created a poetic transmediation of Kinect motion capture data into a tactile output. His intent was to explore devices to assist in the translation of visualised motion into haptics: pragmatically, this is a prototype of a device that might assist people with visual impairment; poetically, Ghaly enacted a synaesthetic transition from the kinaesthetic realm into visual data and then to tactility. According to an aesthetics of immanence it is possible to ask what disappears through this sliding across sensory registers, and what is gained when something of oneself is externalized, possibly shared, and then returned to oneself: like falling asleep and then waking up, the same but different.

There is, of course, a long tradition of dancers considering tiny, repetitive, or pedestrian motions, or recently of dancers simply refusing to dance. This has been done with a sense of defiance but for some reason I am reminded of Efva Lilja's choreographic experiments on arctic ice. She set up a video camera on a tripod near the Nordic research ice-breaker where she voyaged with other scientists and, in her bright red foul weather suit, she repeatedly stood and fell, with the wind and snow whirling around her. These simple acts of falling and getting back up revealed much about motion and corporeality, captured

and archived by digital video. 'Micro Mocap' intends to be spectacularly underwhelming, but revealing of the minutiae of dance in everyday life.

In a discussion with an interaction designer recently, he asked why he should consider performance and performativity in conjunction with his work. This sort of question, so basic but at the same time encompassing, stopped me in my tracks for a moment, making me question my own assumptions and put deeply held convictions into words. "Consider performance," I said making some disciplinary translations in my head as I spoke, "if you want to reflect upon your design work in terms of dynamic patterns of actions, and if by creating interventions you hope to disrupt social structures or codes, or hold a mirror up to yourself or your culture." In this sense, from the cosmological to the mundane, motion capture performance experiments can be used to reveal what we are as intercorporeal beings and how we dynamically inhabit in the world.

Or could they could become very personal movement vocabularies, immanent motion, a part of one's life to save as an archive or edit together into a choreography and send to someone. Like a gift.

THE BIRTH OF MEMORY FROM THE SPIRIT OF THE MACHINE

ANDREAS KRATKY

The computer is a machine of the future – not only do we still attach to it the connotation of technological sophistication and future orientation, also in its function as an information processing machine it only deals with the present, calculating towards to future. In the project “Bleeding Through” we use a database structure and signifying chains to explore the past and the subconscious processes of meaning creation described by Lacan.

Bleeding Through – Layers of Los Angeles 1920-1986, 2002, Rosemary Comella, Norman Klein, Andreas Kratky, computer-based interactive installation, Copyright by the authors.

INTRODUCTION

The computer is an amnesic machine; and it is a machine of the future. It appears in most of the science fiction imaginations of the future – shaped different ways, sometimes giant, sometimes minuscule, sometimes steam-driven as in the steampunk imaginations – it always belongs to the future. The computer still has an association of “high-tech” joined to it. How can a machine that is so inherently linked to visions of the future be used as a conduit for a reflection of the past? And how can a machine that purges everything from memory when the power is off be used for a reflection on memory? In the interactive database novel “Bleeding through – Layers of Los Angeles 1920–1986” we are developing an interaction method embodying the process of memory and the interplay between personal and collective memory. “Bleeding Through” is conceived as an interactive DVD-Rom by Rosemary Comella, Norman M. Klein, and Andreas Kratky. [1] It is produced as a joint research project by USC’s Labyrinth Project and the ZKM | Center for Art and Media.

The inspiration for the piece came from Norman M. Klein's book "The History of Forgetting", where he digs into the urban restructuring of Los Angeles and how traces of the old are remembered and forgotten. Klein uses the notion of 'simultaneous distraction' as a concept to describe how memory is constituted by a continuous and self-corrupting process of inscription and re-inscription – a "distracted imaginary, essentially a filing system where information disappears or reforms itself whenever you touch it." [2] This notion of a 'distracted' filing system is somewhat close to one of the central metaphors of the computer, which, besides its capacity to compute numbers, is in many applications a large storage unit or filing system. But what actually is the relationship of the computer and memory? This is one of the central questions motivating our research into how to represent the process of remembering and misremembering algorithmically. We explored this question with an excavation of the complex layering of past and present in one central area in Downtown Los Angeles. Guided by the story of Klein's fictitious character Molly, we built a comprehensive archive of photos from different time periods, re-photography, film, newspaper clippings, maps, interviews etc. that is assembled in a digital database, which can be explored by the viewer through a narrative interface. This paper discusses the process of conceiving the interface and traces the conceptual decisions behind its design.

COMPUTERS AND MEMORY

The person who coined the term "cyber", which has become the prefix to many of the computer-related concepts and contraptions, Norbert Wiener, describes the relationship of the computer to the past and memory as a function of two extremes: First, a very fast short term memory that is necessary in order to keep the values that are necessary for the ongoing calculation at hand. These intermediate results are of no use anymore once the process is completed and at this moment the memory used to store these values should immediately be emptied and made available for new calculations. And second, the opposite of this fast memory is the long term storage, the "memory which is intended to be part of the files, the permanent record." [3] Disregarding the long term storage, Wiener's view is focused solely on the processing unit that gets entirely emptied after a completed run of its process to make room for the next process to run on the machine uninhibited by previous results. The human, in contrast, never completely clears what is stored in memory and thus should be situated somewhere between the two extremes that Wiener describes, as "the analogue of a single run of such a machine." [4]

The engineering effort of Wiener concentrates on making the machine memory as precise as possible and keeping the information, once stored, intact and repeatable until it is intentionally erased. In this sense one of the predominant concerns of the cybernetics researchers was to identify a method of distinguishing discernible information from distorted information that disappears in noise and becomes unreadable. Noise in these information transmission systems is the influence of the environment: "It is unfortunate that certain things are added to the signal which were not intended by the information source. These unwanted additions may be distortions of sound or static, or distortions in shape or shading of picture, or errors in transmission." [5] The technological aspect of layering uncontrolled signals from the environment with the intended information can be seen as a parallel to the notion of memory "distraction" that Klein alludes to. Since the days of Wiener and Shannon the information processing machines have made great progress, the computer is a perfect amnesic machine that can forget everything on command and that got rather good at isolating the wanted bits of information from the unwanted. The machine has only two states: Either full recall or complete forgetting. For the human being it is not possible to simply forget everything. Most human beings are indeed somewhere between the two extremes: unable to recall everything and equally unable to forget everything. Klein also alludes to Borges' story of "Funes, His Memory", a man who has perfect recall. After an accident Funes has the

ability to remember everything, even the slightest detail, and in view of this immense amount of data he became unable to go through his recollection again, as it takes more time to go through everything that is remembered than it takes to live the event. Thus he only two or three times reconstructed an entire day. Funes came to the resolution that he should restrict his past days to a recollection of some seventy thousand moments ordered by numbers – but he realized that he would probably by his death be done with classifying his childhood memories and dropped this endeavor. [6] Voluntary forgetting and selective memory are hard to achieve. The human brain seems to be constructed to fulfill this filtering function completely by itself, without conscious intervention. This is a characteristic that would call for an ‘imperfect machine’ in the sense of Wiener and Shannon and the opposite of the ‘pure machine’ that Edgar Allan Poe develops in his analysis of the “Turk”, a chess playing automaton made by the inventor von Kempelen. The chess automaton was a supposed mechanical machine that was able to play chess and that won most of the games it played, in very few occasions it lost. Poe states that a ‘pure machine’, would show no irregularities, and it would always win – therefore the chess automaton could not be a ‘pure machine.’ [7] As we know it was not a mechanism, but a human operating the “Turk” in reality, and it was the human brain that was able to establish this middle ground between absolute perfection and imperfection.

In his essay “A Note on the Mystic Writing Pad” Sigmund Freud describes a mechanical device that embodies the characteristic of this middle ground, a memory support that is able to harmonize the opposition between a lasting storage of information and the erasure in order to make room for new inscriptions. What he describes is a children's toy, a writing pad with a wax layer onto which a sheet of paper can be pressed by writing on it. The areas where the paper sticks to the wax will show the trace of writing, while the others wont. By lifting off the paper from the underlying layer of wax the writing becomes invisible on the surface, but it stays as an engraving in the wax underneath the paper. This combination of an always fresh writing surface, ready to take new inscriptions and a remaining trace, that gets altered each time new inscriptions are made but still preserves traces of the prior impressions is for Freud an allegory for the human capacity of memory. [8] What seems to be possible with the mechanical device is a serious challenge for the digital machine. As the computer is made to be precise and all its elements are designed with the goal of the ‘perfect machine’ in mind, this kind of unreliable inscription is hard to achieve – what would be an algorithm for selective forgetting, or what should be the heuristic to select what should be forgotten versus what should remain? What are the alterations that are produced through new inscriptions? Not only it seems that it is hard to design algorithms that are made to produce irregularities – as we know, even real randomness is almost impossible to achieve with the computer [9] – it also seems to be in the human psyche to not want to intentionally loose anything. All our tools are made to preserve and keep, from the stone inscription and the note pad, to the museum and the database.

CALCULATING THE UNCONSCIOUS

There is a different way of conceptualizing the relationship of the computer to the past: Another story of Borges, the “The Library of Babel” describes the idea of a complete library, a library that contains all books, all that have ever been written and those that will ever be written. In this library it is sufficient for a book to exist that it be possible [10] – the library is the hypothetical construction of the space of all possible recombinations of the set of the alphabet. The books are thus not seen as meaningful entities but as instances of a possibility space – where meaningful combinations might be the exceptions. This perspective of a library is without any past, as “it has existed ab aeternitate” [11] and will exist eternally – it is the tireless activity of a probably very simple recombinatory algorithm, which does not need to

keep any information about the past. Based on the transformation rules of the algorithm it is possible for every possible state to calculate the next state. The implication here is that every seemingly meaningful experience can be seen as a simple combinatory instance of such an algorithm.

The Russian mathematician Andrej A. Markov has investigated this idea and in a parallel to Borges' later story he used a book for his experiment. The inventor of the Markov chain, which, named after its inventor, later became an important mathematical device, determined in a detailed analysis of the pages of a book in long matrix calculations the probability for character sequences to follow each other. As his study object he used Alexander Pushkin's novel Eugene Onegin, which for him became the abundant source of combinatory instances of character sequences. The probability chain that he identified represented a pattern that is sufficient to predict the continuation of the sequence without regard to the content of the surrounding text.

Markov's theory of signifying chains inspired later Jacques Lacan to formulate his theory of the unconscious as a chain of signifiers that determine the subject. A specific symbolic sequence akin to the Markov chain governs like a formal language such psychological effects as remembering and repression. [12] Lacan saw this chain also as the explaining principle for what Freud called the "Wiederholungs-zwang", the compulsion to repeat. He writes "we can find in the ordered chains of a formal language the entire appearance of remembering, and quite especially of the kind required by Freud's discovery." [13] Lacan sees the ordering principles inherent to this kind of formal language, expressed as a chain of probabilities for a specific sequence, as determinant for the acts and subconscious affinities. Rather than explaining these acts and associations as stemming from past experience, they are the results of a probability structure that is almost like a 'personal formula': "This could illustrate a rudimentary subjective trajectory, by showing that it is grounded in the actuality which had the future anterior in its present." [14] The intuition behind this formula relates directly to a computational approach and Lacan suggests that it would be possible to conceive of a modern calculating machine, a "thinking machine", to operate according to the specific formula that modulates a subject's choices. [15]

INTERFACE ALLEGORIES

For our design of the interface for the piece "Bleeding Through – Layers of Los Angeles 1920–1986" we were looking for an approach that could on both the functional level as well as the aesthetic level embody aspects of the "distracted imaginary" process of remembering between personal and collective memory, and fiction. Our goal was to conceive what I called an "allegorical interface," [16] an interface that constitutes a figurative or symbolic representation of the core aspects of the media text that is experienced through this interface. As in an interactive medium the functional dynamic aspects are an integral part of the experience, they are in extension of the visual, textual, and auditive elements conceived of as a procedural allegory that embodies aspects of the processes described in the media text.

The idea of a signifying chain formulated like an unfolding syntactic structure that develops based on an interplay between transition probabilities from one state to the next and the subjective acts of choice of the viewer is the central idea for the functioning principle of our interface. We conceived of this chain as a sequence of presences and absences that formulates a "scansion," [17] as Lacan calls it, a rhythm of 'slots' that are filled as the viewer navigates through the piece with elements from the database. The elements from the database take the role of associative presences that enable the viewer to fill in the absences, the gaps between the loosely composed elements, with his imagination. The act of imagining is thus initiated and guided by the succession of database elements and, framed by the story that Klein

invented, the imaginative activity of the viewer fills in the reading of these elements as possible characters of the story, possible places where the story may have taken place, or possible events that could have influenced the story. All the elements oscillate between their role as a document that shows places, people, and events in the real history of the city of Los Angeles, and the role they assume in the progression of the fictional story. In this way the imagination of the viewer is invited to interpret them in both ways, as historic traces as well as fictional elements, and contribute their background and experience to the multi-layered experience. As the viewer navigates through the materials, they line up in an endlessly cycling chain in which the succession of elements is determined by the choices of the viewer and a probability ranking based on a keyword system that we extracted from the story.

Visually this chain is implemented as an allegory for the act of strolling through a city where the viewer is exposed to a continuous succession of impressions that unfolds as he goes forward. A central panel shows one element from our database that can be explored in depth to reveal its historic context, such as a cross fade of historic images with their contemporary rephotographed view, further explorations of a specific location etc. Left and right from this central panel are images that are only partially visible, cut off by the borders of the screen, which stand for the elements in the peripheral field of view attracting the viewer to divert left or right. As he chooses one of them, this element swings into the middle position revealing another element on its side. In this way the elements succeed each other in an endless chain, which may show repetitions but repeated elements always appear in a different context so that the recombinant principle incites new readings and contextualizations even though elements appear familiar. We see this process as a re-encounter of a familiar object or image, which is always altered by the past experience and thus never the same as it was when it was first encountered, thus implementing an allegory for the simultaneous distraction of memory through the ongoing process of inscription and re-inscription.

The visual form of this interface is a long panoramic strip akin to the perspective of going through the city. On the other hand it evokes associations of a film strip or an editing machine underscoring the role of media and their representations in our memory process. In particular in a city like Los Angeles this latter association underscores the influence that media representations have on collective memory and individual perception.

CONCLUSION

The Markov chain implementation as the algorithmic principle behind the experience of “Bleeding Through” is compelling from a theoretical point of view and in practice delivered the anticipated results. We realized, though, during our production that a careful fine-tuning of the process was necessary to achieve the “middle ground” between mechanical perfection and ‘subjective distraction’. Finding the right keywords, the right amount of keywords, and the correct probability weightings was a process of trial and error, which was not only restricted to the fine-tuning of the engine but also required us to make adjustments to the database. We also found that in order to make the process of memory inscription and erasure noticeable and develop the right narrative tension, we had to limit the amount of presented elements at a single viewing to a subset of the available database. Further it was necessary to implement several kinds of layering systems that introduce an additional superposition of images and meanings to add more depth to the recombination engine.

Through several user studies we found that the process of eliciting associations and stimulating the imaginative engagement of the viewer with the experience worked well. And even though the principles

that are at the basis of the combinatorial process of the work remain hidden to most viewers, it still is effective on the perceptual level and presents a compelling heuristic for design principles.

THE MUSEUM MACHINE - OR - A DATABASE APPROACH TO THE REPRESENTATION OF SPACE

Andreas Kratky & Juri Hwang

We generally think of space as a coherent and continuous extent and the representation of it is dominated by the linear perspective. In the project “Venture to the Interior” we are formulating a database approach to the representation of space. We are creating a hybrid mixed-reality environment that integrates multiple points of view and allows to explore a layered structure of parallel spaces.

Venture to the Interior / Vorstoss ins Innere, 2010, Juri Hwang and Andreas Kratky, computer-based interactive installation, Copyright by the authors.

In this paper we will discuss the methods and design considerations that we developed for the creation of the Cine-Interactive “Venture to the Interior / Vorstoss ins Innere.” The project is a real-time 3-d environment that investigates the nature of the museum as an apparatus of collecting and cumulative knowledge construction. We used the collections of the Natural History Museum in Berlin, Germany, as an example case for the act of collecting as a way of understanding the world. With the project we are looking at a tradition of collecting objects as part of an emerging scientific practice and worldview that originated during the Renaissance period, when the first private collections were formed in the 15th century, [1] and that had its high time as a public institution during the age of enlightenment and the 19th century. Collecting material objects was regarded as a prime way to gain knowledge since then and only lost its primacy in the recent years around the end of the twentieth and the beginning twenty-first centuries, when the material object got replaced more and more by its coded representation in form of DNA sequences, scans, and measures, and when the museum as a spatial construct started to fade behind the ubiquitous databases. [2] With our project we are reflecting on the status of the object and its representation, and the museum as an architecture of knowledge – a spatial construct that embodies a particular worldview. In creating a virtual representation of the museum and its objects, we are on one hand contributing to the virtualization of the material culture of the museum while at the same time raising awareness and questioning this very process. The question of representation of objects and space is therefore a key element of the project.

THE IDEA OF THE MUSEUM

What gets lost in the reduction of objects to their data representations is the material existence of tangible objects and their binding to a location in a spatial continuum. It is a turn away from the material culture of knowledge that was established in the Renaissance period and dominated the natural sciences for a long time.

Among the Renaissance savants the possession of objects was equal to the possession of knowledge. In the acquisition of such objects – preferably exotic objects, such as birds of paradise or fossils – one could physically acquire knowledge and display the possession of it to gain the reputation of a learned person. [3] Building private collections was a popular activity among the upper class along with the creation of spaces to display these objects as a way of showing economic wealth as well as knowledge. It was an important part of learning about nature and it was the foundation of a particular material culture as part of the sciences that moved away from studying the antique texts as the source of knowledge and towards an experiential contact and engagement with nature. [4] The museums of the early Renaissance – more cabinets of curiosities than museums akin to our modern concept of museum – were architectural structures representing the order of the world according to the “book of nature”, and displaying the secret relationships between the objects was a way of deciphering this book and the divine order of the world. [5] The spatial arrangement and the act of “taming” the wild beasts on a shelf in a collection was also a way of maintaining some control over the exploding natural world that was constantly growing in complexity as travel and increasing knowledge revealed more of it. [6] These early collections were conceived around their owners as the central figures. Representing the world from their point of view, the collections were at the same time reflections of nature and of the individual self. This importance of a spatial ordering system persisted when the majority of the private collections became public institutions and as museums became a display case of national importance and pride.

The other aspect that gets lost by the replacement of the object with its data representation, is the aspect of reality. Even though the real object needs to be preserved in order to survive over time and become the eternalized reference for a species, and the wild animals need to be killed and transformed into a taxidermy in order to be stored in a cabinet, they still preserve a reminiscence of their individuality and the reference that they once were living beings. And even though the taxidermy is in some sense also a representation, as one single dead instance stands as *pars pro toto* for entire species of living creatures, the data object in contrast does not have this reference at all and thus lost its direct connection to the world.

THINKING ABOUT PERSPECTIVE

With these considerations in mind we developed a spatial concept for our project that allowed us to address these questions and make them tangible. As a central element of the project we decided to create a virtual representation of the museum space itself as we found that the actual built space is the core element in the function of the museum as a collecting, ordering, and display system, and it is the stage of the play of representation versus the object. This virtual representation is conceived as a real-time 3D environment that users can explore at will using a common game-engine. The way most software represent space as a virtual entity on the screen follows the principles of linear perspective as it was devised by the Italian Renaissance architect and artist Filippo Brunelleschi and that had its first description in the “*costruzione legittima*” by Leon Battista Alberti in 1435. A good description of this perspective approach can be found in Erwin Panofsky’s seminal essay “*Perspective as Symbolic Form:*” The way we see

a perspectival representation of a space is as a “planar cross-section through the so-called visual pyramid; the apex of this pyramid is the eye, which is then connected with individual points within the space to be represented. Because the relative position of these ‘visual rays’ determines the apparent position of the corresponding points in the visual image, I need only draw the entire system in plan and elevation in order to determine the figure appearing on the intersecting surface. The plan yields the width, the elevation yields the height; and if I combine these values into a third drawing, I will obtain the desired perspectival projection.” [7] This construction renders a continuous and homogeneous space, but in order to realize this impression and to absorb all content into one single “quantum continuum”, as states Panofsky, it has to be assumed that there is a single viewer who sees the scene only with one eye and that the planar projection of the space can be seen as a valid representation of our spatial perception. [8] This notion of linear perspective corresponds rather closely to the way the collections of that time were conceived – a perspective of the world of which all lines converge in the one person, the collector, at its center. This way of representing the world was shattered by the development towards modern science.

The computer generated real-time rendering is not per se constrained to the assumption that the viewer stays immobile as is the case in static linear perspective constructions, since the viewpoint is continuously updated to the current position of the viewer. But nevertheless, most computer-based perspective constructions adopt the postulate of the continuous and homogeneous space. There is still only one single point of view from which the entire world falls into place and is displayed correctly. These are abstractions to which we are so accustomed that we almost accept them as natural. We have seen them throughout centuries of painting, in almost all of the photography, and finally we see them taken over in most of the computer graphics imagery. It is for this inherent feeling of natural perception that computer graphics go generally with linear perspective, even though the machine would be perfectly able to generate all kinds of other representations of space that follow different mathematical models, such as Michael Noll’s four-dimensional hypercubes, [9] or fractal geometry.

BAROQUE PERSPECTIVE

While linear perspective and the Renaissance collection correspond strongly in their way to represent the world, the modern museum stands for a different perspective. Even though it is equally conceived as a location within which all things in the world fall into place and in this way constitutes one big system of order and knowledge, it realizes this notion based on other abstractions. In order to represent entire species, single individuals are collected; likewise single objects stand as representations for entire regions. The museum space in fact presents itself as a system of references reaching out into the world – like a space that is folded over and over to encompass and absorb all the distant locations into its own volume. This notion comes close to some of the central elements of the thinking of Gottfried Wilhelm Leibniz, a Baroque scholar who was instrumental in the founding of the museum in Berlin and in the development of the idea of scientific collection and display as a generator for knowledge and further research. Leibniz is well known for the invention of the infinitesimal calculus and his solution for the “quadrature of the circle”. The intuition for his approach to determine the surface of the circle stems from linear perspective eventually dissolving it into a system of floating points of view. The quadrature of the circle was one of the paradigmatic problems raised by the ancient geometers and became a metaphor for an intractable problem. Taking inspiration with perspective construction, Leibniz divided the circle from a single point of view into an infinite series of triangles. The area of each of these triangles can be calculated and therefore the area of the circle can be calculated as the sum of a series of triangles, which can be infinitely smaller and thus the calculation can be infinitely more precise. [10] From

this notion he developed a general approach to calculate any shape or curve by subdividing it into a series of small triangles in order to make it tractable. While this quadrature of the circle solution is still close to the idea of one central viewpoint from which the entire shape falls into place and becomes calculable, the way this concept enters into the philosophy of Leibniz is as a duality of inflection points and points of view of which Gilles Deleuze gives a succinct description in his book "The Fold – Leibniz and the Baroque". The point of view in this model is the point at the interior of a curved shape where all the perpendiculars to the tangents of this curve converge. The inflection point on the other hand is the point where a curve changes its direction. As the Baroque curve is marked by an irregular and changing curvature, it is described by an infinitesimal series of directional changes. We can see it as the complement to the vectors on the interior of the curve converging in the point of view, as a series of divergent vectors reaching into infinity. [11] This concept of an endless variability implies that the resulting space circumscribed by this curve is characterized by multiple points of view that change their positions from the interior to the exterior as the curvature shifts from concave to convex and back. This Baroque extension of the perspective view as it was formulated in the Renaissance, introduces a relativism that perceives space as the sum of a multitude of points of view. It constitutes space as endlessly folding between local discontinuities within a large continuum. This is what Deleuze calls the "very idea of Baroque perspective." [12]

A DATABASE APPROACH TO PERSPECTIVE

This inspiration about the representation of space and the idea to extend the linear perspective as it is implemented in most computer graphics applications led us to the development of a hybrid approach that we call "database perspective". It integrates the familiar linear perspective construction with a series of defined relative points of view and allows us to address the composite nature of a collection that draws a comprehensive picture of nature from an almost endless amount of collected individual objects. It uses the idea of a folding principle connecting the museum building to the various locations out in the world and, by referencing the idea of a continuous shifting of viewpoints and the successive "falling into place" of the perspectives, gives a metaphor to the procedural nature of the ongoing and by definition never finished project of collecting. The concept of cumulative knowledge construction as it stands behind the idea of the museum is an endless process of generation and revision of knowledge.

The layout of spatial elements in our project uses the museum as a central hub that is explored by the user. The museum is represented as an abstract space consisting of the floor-plans and elevations of the original building as it is described in the quote from Panofsky above. Using the line drawings of the plans gives us the opportunity to evoke the notion of the building of knowledge as an imagination and points the viewer to the fact that the museum itself is an abstraction and idealization made regarding the human understanding of nature. It appears as a line drawing delivering associations on one hand to the architectural plans of imagined buildings yet to be completed, and on the other hand, it is akin to the wireframe images evoking the imaginary worlds of virtual reality as they have been established as classic notions of computer-culture by media pieces such as the Gibson novel "Neuromancer," [13] the film "Tron," [14] or the game "Rez." [15] From this central hub the viewer can access multiple "context spaces", which display certain topics and explore other locations and times, such as the submarine fauna or objects from the 'Wunderkammer'. The viewer can access these spaces by passing through objects located in the virtual museum that serve as representations of and portals to the "context spaces." The geography of these spaces and their relationships to each other are organized in a recombinant database structure symbolizing the references and vectors reaching out from the museum into the world

and that follow the intuition of a folded space with various extensions, which are only possible as virtual spaces in a virtual architecture.

The central museum space is filled with photographic images of the actual museum building, arranged in the virtual space according to the perspectives from the various points of view as they were taken in reality. The resulting impression of the space is a composite akin to a spatial collage of images that fade in and out as the viewer passes through the space and approaches the various points of view. We have adopted a similar concept for the representations of the objects in the museum that serve as portals to the context spaces. Each object is represented by a series of photographic images of the real object showing the different sides of it, which are displayed as the viewer moves around the object. All sides of the object are shown in ten degree steps and imply the notion of continuity and three-dimensionality while at the same time communicating the gap between the individual representations, much like the idea of an infinitesimal series – coming close to the original but never reaching it. Our decision to use photography in combination with a computer generated space was motivated by the desire to evoke the reality reference of the objects and contrast it to the abstraction of pure data representation. As Roland Barthes describes, photography has the power to evoke an idea of direct reference to the object that was photographed, much as the reality reference of the taxidermy in the museum: “The photograph is literally an emanation of the referent. From a real body, which was there, proceed radiations which ultimately touch me [...] like the delayed rays of a star.” [16]

As a way of overcoming the abstraction made by most of the linear perspective constructions, the restriction of the view to one single eye, we decided to present the project as a stereoscopic three dimensional projection. This significantly heightens the immersive quality of the experience and makes the complex spatial system more readable for the viewer as it uses stereoscopic vision to support his perception and resolve the spatial relationships within the space.

THE MUSEUM AS EXPERIENCE

The reflection about perspective and the representation of space is an important aspect of the the project “Venture to the Interior / Vorstoss ins Innere.” During our research and production of the project we have realized that the specific quality of the space and the distinct feeling of historic presence that spans many centuries are essential aspects to communicate. We have used the representation of space as a symbolic way of communicating these feelings and allowing the viewer to enter a space that is normally inaccessible, as, in contrast to the show-collection, the scientific-collection, which is the largest part of the museum, is not publicly accessible. These decisions are important aspects of the communication process and warrant careful consideration, they should not be left as contingent on the tool that is being used, as there is no neutral or, as James Elkins writes, “meaningless perspective.” [17] With the reference to Leibniz we are alluding to the notion of the museum as an educative and entertaining experience that he formulated in 1675 in his text “Drôle de Pensée” and where he described the use of exhibitions, machines, and all kinds of media spectacles as a way of fostering scientific engagement and as a generator for new insights into nature. PROGRAMMABLE SPACE

Sam Kronick

This paper draws an analogy between the development of the programmable computer and conceptually related projects to develop programmable architectural *spaces*. I propose that the computational power of mobile devices and augmented reality technology can be used as a method of revisiting these utopian dreams. In this spirit, I lay out the plan for a software toolkit for such mobile applications titled *Urban Space Program*.

System overview for the Urban Space Program augmented reality toolkit, currently under development by the author.

The Program Metaphor

In the field of architecture, the term “program” refers to the types of spaces to be included in the building or set of buildings— a university’s program would call for classrooms, auditoria, dormitories, food service, etc. The architect’s job is, in part, to shuffle around the building masses necessary to house these functions into an effective form. Whereas most architecture renders the program static, a distinct movement of mid-20th century avant-garde architects focused on the design of frameworks or superstructures into which various programmatic elements could be inserted, removed, and replaced with relative ease. Such dynamic architecture is exemplified by Cedric Price’s *Fun Palace* (1961-1964), Archigram’s *Plug-In City* (1964), Yona Friedman’s *Spatial City* (1959-1960) and Constant Nieuwenhuys’ *New Babylon* (1959-1974). [1] In all these projects, the users of each structure are given agency to reconfigure their environment by moving about walls, staircases, or even entire rooms within a grid of possible locations. In this way, these spaces move from being programmed to become (*re*)programmable. An analogous shift occurred at about the same time as single-function computers (such as World War II-era

ballistics trajectory computers, or desktop calculators) transitioned to the von Neumann architecture of contemporary microprocessors— an architecture that supports interchangeable programs.

Suggesting that space itself can become programmable is not an unprecedented metaphor; software architects have been borrowing language and concepts from their brick-and-mortar counterparts for decades. Examples include Eric S. Raymond’s seminal paper *The Cathedral and the Bazaar*, [2] Mac OS X’s “Core Foundation” API, Ruby on Rails’ “scaffolding,” and the general focus on “software patterns” (including the “factory method” pattern) which implement the style of thinking suggested in Christopher Alexander’s *A Pattern Language* [3] far more extensively than the architects for whom it was originally written. Curiously, this conceptual crossover has been largely one-directional. Contemporary architectural discourse is rife with discussion of how best to use software tools like CAD/CAM and Building Information Modeling systems, but, except perhaps for a few loose interpretations of the term “Open Source,” [4] the philosophy of software design has not had a great impact on the art of making space.

Challenges of Programming Space

A possible explanation for this asymmetry is that making physical space programmable isn’t as easy or effective as it looks on paper. Take, for example, Japanese Metabolist Kisho Kurokawa’s *Nakagin Capsule Tower* (1972)— a rare example of built architecture that embodies principles of modular, interchangeable components. Its 140 micro-dwellings are designed to be removed from its two central towers and replaced every 25 years. Thirty-nine years later, the capsules are hopelessly outdated (with their built-in reel-to-reel tape decks and corded telephones) but replacing them with new modules has proven difficult to organize and finance, so the building as a whole is at risk of demolition. [5] It is likely a similar fate would have met the other avant-garde designs would they have been built, too.

Nakagin’s capsules seem to be more inspired by the industrial revolution’s notion of interchangeable parts than the computational revolution’s interchangeable programs. Thus, Nakagin and other blueprint-based speculative architecture can be read as analogous to the mechanical analytical engine of Charles Babbage, an early computer that aspired to do with gears and levers that which was ultimately only made efficient through the transmission of electrons. [6] In an era of cheap digital computing, these architectural visions from the past century deserve a fresh look. Not only are computational tools unthinkable more powerful than they were when Archigram and the rest were designing, they also embody the notions of portability, ubiquity, and pop-culture integration that fueled these designers’ visions. With a mobile phone in the pocket of an ever-expanding percentage of the world’s population, the low costs of experimenting with software provide a viable alternative to periodically retooling factories as a means of reprogramming space.

Of course, the challenges of making a physical space programmable are not just technical or economical in nature; there are social barriers to achieving a critical mass of spatial dynamism as well. Architects like to think that everyone is as interested as they are in contemplating the buildings around them as a part of everyday life. The mid-century avant-garde was no exception; Price’s *Fun Palace* was pitched as a viable business model for a citizenry that would crave spatial reconfiguration as a weekend leisure activity, and the imaginary species *Homo ludens* set to inhabit Constant’s *New Babylon* would not only be allowed but expected to build diverse spaces inside a maze of homogeneous, standardized parts as an act of play. That people would jump at the chance to engage with such systems seems a misguided assumption.

tion in hindsight. In revisiting these visions, it might be best to look at a growing contemporary subculture that already has practice in the sort of spatial literacy needed to take advantage of reprogrammable space to its fullest. Here, the popular model of video gaming can provide guidance.

Virtual Games to Augmented Realities

Some of the most successful video games explicitly use space as a core gameplay mechanism. Maxis' *SimCity* outright casts the player as an urban planner with no other reward than those that come from implementing a satisfying plan, while newer games like Valve's *Portal* series require a player to keenly read the walls, voids, and walkways, of the surrounding space and precisely alter its topology in order to reach the next level. There are plenty more examples of interesting game spaces, but perhaps the most relevant to the mid-century avant-garde is Mojang's *Minecraft*. [7] This low-budget indie hit takes place in a world made entirely of one-meter cubes that bears a striking resemblance to the sprawling overhead grid of Friedman's *Spatial City*. The gameplay stems from the fact that this cubic world is entirely mutable. Every cube can be "mined," carving out voids into the terrain, and subsequently replaced to build up structures with the radical variety of LEGO bricks. Its two-button interface (left click destroys cubes, right click places a new one into the grid) perfectly captures the duality of literacy that is an ability to both read as well as to write within the grammar of a given system. A careful balance of gameplay combined with this novel building mechanic creates a highly addictive experience. The result is a user base of millions; *Minecraft*'s multiplayer worlds are teeming with activity that would make any participation-hungry architect jealous. *Minecraft* demonstrates that gaming is a format full of deep incentives for participation, capable of training actors to effectively transform their world. What *Minecraft* lacks (along with myriad other "virtual worlds"), however, is the connection to the physical cities that interested the avant-garde as spaces ripe for critical intervention— spaces that might be the foundation for widespread social reform or political revolution. This is where we must depart from purely synthetic spaces and move into the hybridized space that augmented reality can provide.

Augmented Reality (AR) is a general term that suggests a perceptual blending of the physical with the virtual. At this point in time, it primarily refers to the computer-aided superimposition of textual/graphical annotations or 3D geometry over a live video feed. The format most relevant to the discussion at hand sites these functions inside a mobile phone or tablet computer— computational machinery that contains a critical combination of portability, ubiquity, processing power, location-awareness, and wireless networking which could facilitate urban-scale exploration by a multitude of users. Not only does AR hold potential for its ability to fuse engaging synthetic game spaces with socially meaningful physical places, it works on the level of vision, augmenting the image of the city and thus connecting to a primal sense of how we perceive ourselves as inhabitants of the surrounding environment.

As masters of visual presentation, architects have long been working with a sort of proto-AR to communicate their ideas. Yona Friedman's sketches for *Spatial City* were often drawn over real photographs of the existing city, using what currently is as a starting point to show what could be. The overhead maps of Constant's *New Babylon* were made from cut up pieces of other maps, pasted as an overlay onto the intended site. Archigram was famous for their use of collage to illustrate how their radical visions might look in the context of a familiar space. While these images were static and captured only a moment in time, they represented plans for vibrant, active spaces. The real-time, on-site nature of AR has potential to extend these composited, active urban plans of the 20th century with the socially-networked, interactive technology of the 21st.

Form Follows Framework

Bringing all this together seems too great a task to be accomplished by a single piece of software. One great AR app will not change the world, just as one Metabolist capsule tower could not transform millennia of architectural wisdom about the importance of permanence. Fortunately, an alternative path can be discerned by hybridizing the historical precedents with the practices of contemporary software design. The mid-20th century avant-garde did not aspire to design singular monuments; instead they focused on the production of systems which would facilitate a certain kind of desired activity. Form followed framework—the latter manifest as structural steel beams, service hookups, communications equipment, and machinery to manipulate modular substructures. Even after years of development, the physical design for the *Fun Palace* consisted of little more than a set of towers and gantry cranes that would move along suspended rails to construct the interior under the command of the structure’s spatial programmers. Likewise, the notion of a framework in software design consists of a set of algorithms and data structures which are targeted to approach a certain body of problems without solving any one in particular (frameworks exist for robotics, graphics programming, user interfaces, etc). The constraints and structure of the framework define the configuration space of derivative works—the space of all possible programs that could be built on top of what is put forth as merely a starting point. Therefore the framework creates not a single application, but embedded seeds which self-replicate as they aid and influence how others approach the design process. In this way, a multitude of programs may arise that carry on in the spirit of the original framework but also, as products of various programmers’ desires, mitigate the shortcomings or authoritarian impositions of the original structure.

Design Considerations for an Urban Space Program

Existing augmented reality frameworks neither usefully constrain the problem space by targeting a clear set of applications nor do they provide relevant algorithmic tools that are specific to the task of reprogramming the city. What is needed is an AR framework for spatial programming, targeted at the creative coders who use software as a primary means of aesthetic and conceptual communication. Such a framework is currently under development under the working title *Urban Space Program*. In developing this framework, several design choices became clear.

First and most importantly, the framework needs to be able to recognize where in the city a user is located and what they are looking at. This can be accomplished by combining location-aware sensors such as GPS, compass, accelerometers, and gyroscopes with computer vision data gathered through a mobile device’s camera. All existing AR frameworks at this point in time use one of these methods or the other but do not fuse data from both sources. Frameworks that are location-aware without using vision (such as Layar [8] and Wikitude [9]) tend to augment with textual annotations rather than alternative geometries because of the limited accuracy of GPS; pixel-perfect image alignment is only possible through the use of computer vision. [10] In *Urban Space Program*, building facades become fiducial markers; the distinct face of a storefront or tower replaces the blocky black-and-white barcode as a machine-readable identifier. The other on-board sensors help limit the search space of which facades might possibly be in view and, using a set of algorithms called “sensor fusion,” fill in the gaps when no known facades are visible.

Second, the framework needs to be built with a client-server architecture to enable simultaneous augmentation of a scene by multiple users. If all data were stored on each user’s mobile device, changes

made by one user would not immediately be available to another user in the same area— this would create a fundamentally single-player experience that runs contrary both to the social act of building promoted by the historical avant-garde and the multiplayer nature of successful contemporary video games. Thus, storage and processing of augmented data and recognizable facades happens on a server and is streamed to the users' devices as they enter a new area and reprogram the space. Rather than centralizing this on one server, the software tools are openly available for installation on any number of servers from which the mobile device can choose to connect to, allowing parallel systems to operate in the same locale.

Third, the database of facades should be built in part with user content. This is suggested as a critique of the historical architectural projects; while designed *for* radical user participation, they were not designed *with* users. In each case the architects unilaterally chose the sites and situations in which activity would take place. In the case of AR, it is easy to imagine that if only the system designer can define which buildings are recognized (and thus which can be easily augmented), this encourages applications of the framework which perpetuate traditional power structures. Recognition of a fixed set of popular landmarks, buildings concentrated in hip districts, or storefronts of sponsoring companies correspond with notions of exploration-as-tourism, advertising, and brand recognition rather than opportunities to truly re-imagine and re-program how a city could be. The Urban Space Program framework includes user interface elements that simplify the process of capturing imagery from a mobile device, processing it for later recognition, and integrating user-captured facades into the database for later retrieval. Of course, the system designer could always choose to exclude these interfaces from their application, but their presence in the framework and presentation as end-user tools rather than developers' utilities suggests that they be included as a sort of meta-game that expands the frontiers of where a particular program can be used.

Finally, if this framework is to connect with a relevant audience of developers, it should tie into existing tools that creative coders are familiar with. Urban Space Program fulfills the role of figuring out where to draw an augmented overlay, but not how or what to draw on top of the live video feed. This latter task is handled by a rendering engine. Conveniently, the creative code community is in many ways defined by the rendering engines it collectively tends to use. Community websites like CreativeApplications.net tag projects according to the rendering framework they use, similar to the way traditional artwork is categorized by material. Tools like Processing, [11] OpenFrameworks, [12] and Cinder [13] are common choices for a growing number of artists and designers. Whereas many rendering engines are set up to produce mainstream video game graphics, the tools for creative coders encourage interactive generative design and abstract visualization of data. Very different results are obtained when images are programmed rather than modeled. Integrating Urban Space Program with these other frameworks will hopefully lead to fresh perspectives on how our cities might function and change beyond the well established modes of representing spaces in photorealistic 3D.

Future Spaces

The Urban Space Program framework represents just one possible way to explore the programmability of space. Augmented reality clearly captures the notion that the image of a place could be altered, though it does little to immediately effect the tangible components of a place. Questions of materiality require other means of investigation. As a software-based media, AR inherently engages with processes and algorithms as a method of producing images, though actually reprogramming the dynamics of an urban environment may call for other interventions. An application that is at its core algorithmic could

hide nonlinear processes and data behind a linear presentation method, playing back fixed narratives rather than the branching paths of participation proposed by the mid-century avant-garde. Gaming is a broad category covering numerous ludic activities and discerning exactly which mechanics can best transform contemporary urban spaces is another field of inquiry in itself. Urban Space Program does not attempt to resolve all these issues. Rather it is an attempt to reconcile present technologies with past philosophies of space to not only speculate, but actively create possibilities for the near future.

METAFACTION AND THE RHETORIC OF ERROR – AN APPROACH TO ADAPTIVE PERSUASIVE CONFLICT GENERATION

Daniela Kuka

With 'metaFACTION' we invent an experimental semantic tool for critical discourse representation and nonfictional storytelling. Based on our Persuasive Conflict Generation Model, we establish an adaptive documentary style to help people gain alternative access to the structure and mutations of public discourse. Paradoxically, metaFACTION makes use of an error-friendly rhetoric – on a meta-level – as a means of shaping democratic communication.

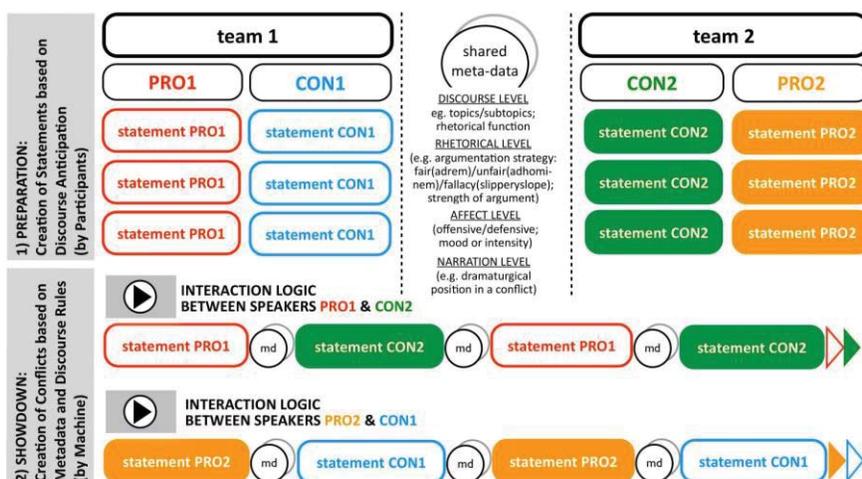

Fig. 1. Exemplary workflow of the formalisation of dialogues with conflicting viewpoints, *Meta-Dating II Persuasion*, 2010, Klaus Gasteier & Daniela Kuka, Schematic representation, Copyright by the authors.

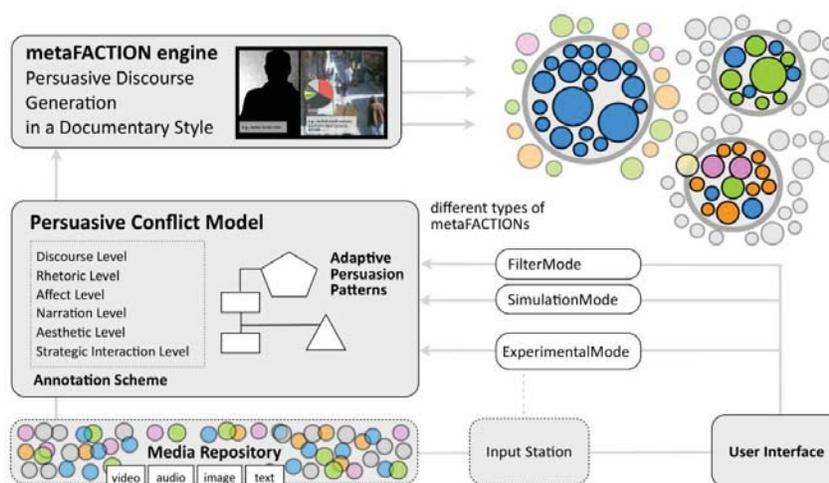

Fig. 2. metaFACTION, 2011, Daniela Kuka, System draft design (representation of filtered versions of mF-documentary following the style of 'filter bubbles'[2]), Copyright by the author.

Imagine we could generate informative and entertaining conflicts from digital resources of discourse such as online magazines, wikis, news portals, blogs, etc. Imagine we could receive them as personalised documentaries instead of lists of articles, references, links and comments – e.g., as simulated panel discussions, TV debates or just everyday conflicts. Imagine fragments of discourse were attracting other fragments of discourse in a dialectical manner, and they would automatically arrange as we are participating in a never-ending global conference ...

Semantic Media shape the way we produce, spread and receive public discourse. Given that discourses in digital archives and the World Wide Web are organised in a nonlinear fashion, we need to conceive of new methods and design approaches to create adaptive representations of topics of societal relevance. With 'metaFACTION' we invent an experimental semantic tool to capture, structure, and reorganise discourse fragments in such a way that informative and entertaining media products with different communicative goals for heterogeneous publics emerge. Combining structural knowledge from Automatic Video Generation, Discourse Analysis and Argument Processing as well as Story Generation with empirically validated patterns to describe natural situations of human dispute or conflict, we suggest the Persuasive Conflict Generation Model. metaFACTION, based on this model, is a conflict machine to create and present divergent and even contradictory discursive formations from a pool of annotated media fragments. The resulting conflicts are contextualised in a documentary-like genre model (documentary films as they are assumed to be persuasive) so that naturally unstructured discourse can be transformed into a semantically enhanced media experience. What is paradoxical about metaFACTION is not so much its capability to contradict itself in a plausible manner, but the targeted use of errors as a means of shaping communication.

The first two sections of the paper discuss current effects from the semantic web as they influence the vision and concept of metaFACTION. The third and fourth section describe metaFACTION with regards to its specific documentary generation approach.

A New Kind of Democratic Communication?

metaFACTION addresses a new wave of internet criticism associated with authors like Cass R. Sunstein, Jaron Lanier, Dean Eckles, and others. In 2010, Eli Pariser introduced the metaphorical term "online filter bubble" to describe how personalised search algorithms start to control how information is presented "increasingly biased to share our own views:"

With Google personalized for everyone, the query 'stem cells' might produce diametrically opposed results for scientists who support stem cell research and activists who oppose it. 'Proof of climate change' might turn up different results for an environmentalist activist and an oil company executive. [...] More and more, your computer monitor is a kind of one-way-mirror, reflecting your own interests while algorithmic observers watch what you click. [1]

What seems to establish from that is a "friendly world syndrome" with "false consensus effects," [2] a hegemonial discourse frame that is immune against critique, irritation, provocation, or alienation, but whose plausibility is always assured in advance owing to the comfortable avoidance of cognitive dissonance. Following Pariser, personalised discourse filters create an intransparent You-Loop around us, a landscape of automated censorship which, paradoxically, is both a black box and generated by our own online activities. Aggregation services and filter algorithms are challenged to cope effectively with an

existing deluge of data that has reached a level of complexity unmanageable by human capacities (cognitive, economic). But can such algorithms be neutral and democratic? They are not simply there to create order and meaning; they are always a step ahead of our decision-making faculty by autonomously selecting, weighting, and evaluating data. They simulate coherence, completeness, and context based on familiar paradigms of reception such as hierarchical, topographical, or chronological order. Behind that simulated order, a new kind of order is emerging: According to "The Order of Things" described by Michel Foucault in 1966, [3] we call it "The Order of Media" which means that there are now semantic concepts and algorithms that govern the production of knowledge and, as a result, people's understanding of the world, their attitudes and behavior.

Digistemes & Unfair Machines

Consequently, in such an "Order of Media" the authors of ontologies and algorithms become the new designers of, again in Foucault's sense, "epistemes", the rules to produce and spread legitimate truths. While semantic concepts determine if and how an object can be described to become part of an order, and if and how it can be related to other objects, algorithms determine how we can access these objects both on general and on personalised paths. This interplay builds a new set of rules to deal with scientific knowledge, cultural artifacts, news, and so on. To adequately describe this phenomenon we invent the term "digistemes". Digistemes are the self-logic of the semantic media dispositif, [4] a highly complex and intransparent set of rules that, on the one hand, allows to produce, distribute and access knowledge. On the other hand, they cause the spread of parallel universes full of zombie discourse, a hidden landscape of disordered unaccessible media fragments. An auto-persuasive human machine network is emerging, a system in which everyone is free to publish anything, but where they cannot or may not see and read everything. Which mutations of a discourse are transformed into zombie data is determined by their capability to provide relevant meta-data to sever the tentacles of semantic search. Otherwise, they remain unable to appear as part of any public discourse.

Thus, digistemes make it appear conceivable that a machine may be capable of automatically generating discourse representations on an arbitrarily chosen topic, using certain pieces of meta-information and coded discourse rules. But should the machine support every user's mindset by adjusting its discourse position to his/her profile? If we intend to use the power of semantic media technology democratically, we have to learn how to use its tools against their own logic (the creation of filtered worldviews). We have to learn how to strategically cooperate with what may be unfair machines (without even knowing if they are). metaFACTION is an attempt: By thinking errors on the meta-(information-)level.

Machine Generated Conflicts

Relevant insights for the research and development process were made possible by a pre-project "Meta-Dating". Meta-Dating is a conception and design project initiated in 2009 by Klaus Gasteier, Professor of New Media at the Berlin University of the Arts. The original idea was to generate plausible conversations about everyday topics from a pool of annotated video clips, based on a collaboratively generated meta-data scheme. Since then this evolved, now as a cooperation, into an experimental environment for non-linear persuasive communication, and a coming series of new approaches. In a team effort, students produce several hundred video clips dealing with anticipatable aspects of a controversial topic of their choice. Having agreed on meta-data that describe argumentative contents, strategies and discourse rules (later transformed to machine-readable algorithms by a programming professional), each team

splits into two subgroups which then develop content for the conflicting viewpoints (taking up both positions in the argument) in complete autonomy, cf. Fig. 1. The project moves a step beyond traditional debating contests: Each subgroup has to anticipate arguments and argumentation strategies for both the pro and con positions as well as patterns of strategic and tactical interaction between the two parties in an ongoing conflict (reaction/action). The computer program then generates the automatic debate (one version of many possible ones). While preparing the needed material the aim is not to anticipate and plan for all possible dialogue constellations, but to find a formalisation model that also supports unforeseeable turns in the final stages. The plausibility and authenticity of the course the conflict takes shows whether or not the model is working.

Persuasive Conflict Generation

To date, Meta-Dating experiments have been focusing above all on a free definition of description parameters and patterns for each project. A theory-driven modelling of argumentation or discourse structures or narration was deliberately avoided in order to simulate seemingly natural dialogues with high flexibility to test different solutions. metaFACTION builds on these experiences and introduces, in contrast to existing approaches in automatic documentary creation [5, 6, 7] and dialectical argument modelling, [8] an approach to model adaptive persuasive communication on natural conflict analysis in human communication. The following paragraphs give a short overview on the main features, cf. Fig. 2.

USER MODELS FOR NONLINEAR PERSUASION

Existing argumentation and persuasion machines do hardly consider that statements have different relevance to different users and that different ways to present a statement affect their persuasive power. metaFACTION follows a "mind opener" approach to documentary [9] combined with user models to generate persuasive mutations of discourse. On this level, we need two different types of meta-data with strategic relevance: a) Meta-data used to direct the dialectical process of two or more parties in order to create a plausible dramaturgy of conflict, e.g., institutional (expert-to-expert/expert-to-layman/layman-to-layman) and social (activist-nihilist/optimist-pessimist) relationships, modes of reaction (offensive/defensive/reflexive), strength of arguments, level of affective involvement (neutral/angry/unsettled); b) Meta-information relevant to personalisation based on user models, e.g., speakers' credibility in different contexts and milieus, speakers' similarity (optimistic/pessimistic, economist/ecologist, manager/mother), values addressed, and so forth.

NATURAL PERSUASIVE CONFLICTS

Related approaches that encode rhetorical patterns are based on formal argument and argumentation scheme modelling. [7, 8] Their insights are integrated in the Persuasive Conflict Generation Model, but we need further approaches to compensate that they create unnatural discourse structures which (1) are hard to capture from organically growing discourse, (2) cannot be used as model for the creation of a whole documentary experience, which consists of a wide range of verbal discourse and visual representations in a dramaturgically relevant order, and (3) are ignorant to the fact that human opinion-making processes do not exclusively rely on logical argumentation. In everyday life, we are affected by personal experience and emotionally intense stories, different hierarchies of values, more or less powerful opinion leaders in our community, misunderstandings, unfair rhetoric, etc. For this part, metaFACTION creates an approach to model human discourse on patterns of natural conflicts as they dominate, e.g.,

panel discussions, TV debates, or spontaneous conflicts in social contexts. Formal Models describing discourse and story structures add parameters and concepts in order to realise a documentary style that is driven by dramaturgical courses of conflict.

OPEN-ENDED PRODUCTION

The related project Terminal Time [6] encodes ideological patterns instead of formal argumentation, but it operates as closed systems. Based on transparent annotation schemes and scalable conflict rules, metaFACTION supports unmoderated peer production on topics of societal relevance. It has to be determined whether sets of meta-data can function as a universal language for micro-storyboards and/or as global stage directions so that anonymous and heterogeneous groups of authors add and annotate found footage or their own statements to create unwritten, typically contradictory, and evolving conflicts.

RHETORIC OF ERROR

Existing approaches try to avoid or minimize errors, e.g., argumentation tools that support decision-making and opinion-making processes. metaFACTION tries to generate a more experimental form of discourse representation. Human beings do not communicate in the mode of formal argumentation. Instead, social communication is context-sensitive and realised in dialectical loops which are rarely free from misunderstandings, coherence gaps, evasion and rapid shifts from topic to topic. More or less unconsciously, we bridge gaps and accept media disruptions, we oversee unfair rhetoric and fallacies, we familiarise with ruptures and lacunae as they are popularised by postmodern film aesthetics and fragmented internet communication. How could our habitual readiness to allow for errors and imprecisions of communication be utilised in a way that enables the manipulation of discourse? We suggest a sense-making false-connections approach allowing metaFACTION to repeatedly generate new arrangements of available media fragments and, therefore, also new statements without paying attention to the primary material's context or intention. Different manipulative principles of montage (known from documentary film theory) are used to build statements and clusters of statements that serve the user. The annotation schemes allow to index media fragments in such a way that they may appear in different, even completely foreign contexts (e.g., by multiple annotations on the discourse level such as science, media, politics, economy, education, ethics, medicine, aesthetics, and everyday life), and also lead to different statements when combined with other media fragments (e.g., by using bipolar fragments that change their polarity depending on their context of use (Kuleschow effect), or by omissions, by polysemy, by framed de- and recontextualisation such as quotation or parody, and by augmenting different context information). As persuasive patterns, we build on psychological and social effects in conflicts such as, e.g., "create fear," "evoke sympathy," "demonstrate authority," or "provoke moral concerns." They can be fulfilled by employing rhetorical tactics such as "quote an expert," "build a positive/negative analogy," "show great/terrible consequences," "tell a story of success/failure," "broaden the topic," "show pleasant/dissuasive example," "attack trustworthiness of counterpart," and so forth.

METAFACTION MODES

The stimulation of the user can occur in three modes. The FilterMode creates a coherent documentary that serves the user's (anticipated) mindset. The SimulationMode allows users to deliberately manipulate the persuasive logic of the engine via an interface. Users can thus playfully experience in this way

how discursive formations and resulting statements are controlled without interfering with existing content. The ExperimentalMode generates documentaries that deliberately infringe discourse and genre rules and thereby open up improbable formations for simulation (e.g., counter-discourses suppressed by mass media, untypical speaker constellations).

Outcome & Future Prospects

metaFACTION allows to simulate different kinds of persuasive conflicts. Resulting media products can be manipulative, entertaining, provoking, or just irritating. Thanks to an error-friendly rhetoric on a meta-level, metaFACTION can serve as a powerful tool for critical discourse representation and nonfictional storytelling. We suggest using the Persuasive Conflict Generation model to establish a new documentary style to help people gain alternative access to the structure and mutations of public discourse in the third generation of the Internet. We are currently working with a prototype version that is to be developed further as an online application.

CORPOREAL EXPERIENCE IN VIRTUAL REALITY

Merve Kurt

This paper will discuss the status of body and corporeal experience in the context of new media art, especially through the virtual works of art that involve digital interactivity and immersion. I will argue that an alternative understanding of aesthetics is needed in art historical and theoretical studies because the experience of virtual reality through new media art reappraise our ways of thinking about pictures and images.

This paper outlines a few ideas about the nature of a new kind of interaction with the art works: an interaction in a bodily way with digital works. This experience is made possible via real-time interactive 3D computer graphics and the resulting enveloping space is called virtual reality. I will argue that an alternative understanding of aesthetics is needed in art historical and theoretical studies because the experience of virtual reality through new media art reappraise our ways of thinking about pictures and images.

To get a clear picture of the notion of virtual reality one should begin with its possible definitions. During my researches, I have realized that there are three different use of the term, corresponding to three different disciplines: science (more specifically optics), philosophy and arts of computer generated imagery. Used in optics, the virtual reality signifies a mirror image. In this context, this term could be substituted with optical illusion. In philosophy, it is defined either as a potentiality in the Aristotelian sense or a hidden, a non-obvious presence in the actual reality. Though in the first context the virtuality is the contrary of actuality and in the second it is already in the actual, both of these definitions accept that the virtual is in the order of reality and it is not its contrary. It is necessary to underline this attribute of the virtual because mostly in the commonsensical thinking we tend to say that if something has a quality of virtuality then it is not real. Yet, it is important to appreciate that virtuality is a part of reality since there is really a virtual reality. And today, when we talk about virtual reality, it has a specific meaning: interactive simulation systems created through computer based three-dimensional imagery. In this paper, we'll use the term in its third sense when referring to virtual reality in digital art.

When we move to the definition of virtual body, we find two different categories. In the field of literary fiction and its declension in films, it is a question of cyber bodies or bodies set free from all material limits. And in the universe of computers, it is a question of a body modelled or moulded by three-dimensional computer graphics, a body immersed in a computer-generated world where a perceptually encompassing environment is created. This experience is promoted either through use of an interactive screen or with head mounted displays combined with haptic and vestibular displays. This device enables the user to complete, extend and reproduce the reality. I'll treat the question of virtual body as it is defined in the second category, meaning as an immersion in an enveloping space created by digital art works.

I disregard if it is an disembodied experience like in the works of Jeffrey Shaw, namely *Place :Ruhr*, or an embodied one like the *Osmose* of Charlotte Davies because in both cases, the body incorporates into images, live them from an intrinsic point of view which could break out the rules of Euclidean space and

the Cartesian understanding of spatiotemporality. Hence this new way of experiencing images arises new phenomenological and aesthetical questions.

In Jeffrey Shaw's *Place: Ruhr* (2000), which is an example for the disembodied experience, a rotating platform allows the viewer to interactively rotate a projected image within a large circular projection screen and explore a three dimensional virtual environment. A device on the platform designed as an interactive user interface, with its buttons and handling, allows the viewer to control his movement through the virtual scene. It enables the rotation of the platform and of the image around the circular screen. The field of exploration is open to other sensory organs than the eye: the spectator uses the virtuosity of his/her fingers, gestures and synchronizes his/her movements with the speed of moving images. The hand wins a control function and the eye interacts with it in order to enter the virtual world. Movement of the body from the physical environment to the space of virtual images is accompanied by a sense of continuity that partially masks the difference between physical and virtual space. The ability to move in the space of images doubles the movements of images on the circular screen. Anne-Marie Duguet mentions that in Jeffrey Shaw's works;

The user enters in spaces without any point of reference, in times without direction and in adjustable speeds. He is both on the stage and out of it. He conceives here and there at the same time. [1]

So the aesthetic experience does not remain only as contemplation, but gains a sensitive and cognitive aspect. We can literally say that the audience becomes one with the work and s/he touches the image. Thus, the interactive device allows participation to an unprecedented and multisensorial experience.

To have an idea about the embodied experience within the virtual universe, *Osmose*, the three dimensional installation of Charlotte Davise, is a good one. Davies, a Canadian artist and the director of Visual Research at SoftImage creates *Osmose* in 1995. She builds twelve natural worlds with the themes like landscape, earth or interior view of a body where it is possible to be immersed and to move with the help of a head mounted display and sensors that capture the respiration and the movements of the user. Immersants are placed in *Osmose* for fifteen-minute sessions. In her paper « Techne as Poiesis : Seeking Virtual Ground » Davies speaks of *Osmose* as being a poesies or bringing forth, revealing our being in the world. The prime navigation tool is the breath. Stephen Jones, when describing his experience in *Osmose*, writes:

On breathing in, one rises through the virtual worlds ; on breathing out, one sinks slowly into deeper realms until one gets down to the core machine-code world. The participant gains a sense of being removed from the everyday world and immersed in some environment that does not necessarily behave according to the rules of the known. [2] Davies explains the audience impact of her immersive virtual artwork:

... judging from the participant response, immersion in *Osmose* appears to temporarily suspend some people's capacity for rational thought and conversation. For many, it is an emotional, even euphoric, experience. People feel free of their bodies and yet, paradoxically, grounded in them at the same time. Some feel an intense sense of loss when the immersive session is ending, and even cry afterwards. [3]

With *Osmose*, one have a better understanding of the virtual space and time which operate under laws other than those belonging to the real world. In addition to these characteristics, the digital images in

contrast to traditional ones do not have a fixed or mobile medium as they are immaterial in their electronic form.

Following these examples, we may say that virtual worlds are non-spaces, which do not exist, in our everyday reality. Yet our bodies in these non-spaces can never be non-bodies. This confrontation between non-spaces and real bodies is the core of the question of the corporeal experience in the virtual. At this point I'd like to analyze its conceptual and sensorial consequences of this confrontation from two perspectives, not so sharply distinct from each other : phenomenological and aesthetical.

What is at issue here, from a phenomenological framework is, as art historian Suzanne Ackers suggests, « Renaissance perspective is displaced, and we are learning new ways of seeing, navigating in new kinds of conceptual space. Our perception of time and space becomes a virtual knowledge, no longer fixed to the Cartesian frame.» [4] So we are placed in an original situation where we can perceive physically a theoretical model and in practice act on its intelligible structure but in a reciprocal way this mediation allows us to think, in other words to understand abstractly and categorically physical sensations and configurations of stimulus sensorial. Henceforth, they offer the possibility to cut ourselves off from the world, not in order to retire but to understand it better, to grab its essence. So, the virtual body is not, as it is commonly thought, a body without corporeal envelope, without weakness, just a body of pleasure. But it is rather a body, which would have the chance to ask itself the question of the man, his status and also his own limits. The virtual reality permits to witness the boundaries of reality through an other form. In a phenomenological context, if we refer to Merleau-Ponty, the body grasps its own immediate knowledge by jutting into the fabric of experimental space and time. And since the experience of space and time changes within virtual environments, we can not speak of body image as a stable entity in virtual installations, therefore we should reconsider it: Is it possible to conceive a phenomenological experience of a new order ? If so, to what extent these new sensations and perceptions would change the phenomenological studies ? These questions could be considered as a basis for a phenomenological theory that remains to be founded.

To experience the visual, aural and interactive aesthetics of the work, we don't really leave our physical bodies but we leave it in an imaginative way. Philippe Quéau, a contemporary French scholar and Fred Forest both artist and art theorist who made a great contribution to the literature of the virtual, announce that the virtual is the vertigo of the abyss. Quéau explains that in German, the abyss is Abgrund, which is the contrary of Grund, the base but also the reason, as Heidegger reminds us. If the virtual worlds excite us it is because they create a sense of vertigo, an emotion of abyss, we are leaving the reason. [5] Virtual installations, by enabling people to experience the unusual sensations of seeing and floating through things, changing them, living them from inside, make them get free of their usual, habitual ways of being in the world. So, as our physical appropriation to the art work, our emotional, sensitive and intellectual relation are deeply modified, we should bring forth a new theory of aesthetics. It would be an ignorant mistake to place new media art in the historical continuity of artistic movements related to contemporary art. We should face the question of digital arts as we do in the scientific domains when confronted with a genuine epistemological breakdown. New media creates an exciting occasion to raise broader questions in art theory, philosophy of art, phenomenology and even in epistemology.

ORIGINS OF JAPANESE MEDIA ART – ARTISTS EMBRACING TECHNOLOGY FROM 1950S TO EARLY 1970S

Machiko Kusahara

INTRODUCTION

This paper excavates and analyzes works of Japanese artists from 1950s to early 1970s that anticipated media art to come, with original ideas and innovative use of technology.

It is never clear when and where “media art” started. However, it is important to trace back its history and examine what may be called “pre media art” in order to better understand media art today. By exploring postwar Japanese art history retrospectively from today’s media art point of view, elements that have been neglected or put aside can be rediscovered with different meanings.

HISTORICAL AND CULTURAL BACKGROUNDS

In order to analyze their relationship to technology it is important to understand the historical and cultural background. Japanese postwar avant-garde artists emerged from a specific situation when the value system went through a drastic change in a short period. Nationalistic ideology that the government had successfully established since Meiji Restoration in 1868 collapsed with two atomic bombs and the occupation that followed. The defeat meant liberation from the exclusionist doctrine that practically banned anything Western or international and praised “Japanese spirit” (yamato-damashii) as the winning force. The American occupation forces overwhelmed the Japanese with their material and technical superiority. To many Japanese it became clear that spiritualism alone could not compete against the power of technology. Interestingly similar to what happened less than a century earlier, Japan was determined to catch up by focusing at science and technology, transforming itself into an industrial country.

However, ultranationalism was not a Japanese tradition. Before the war, especially in the 1910s and 20s, lively urban culture prospered with real-time influence from Europe and America. New trends and movements were introduced in real time. Dadaist movement was introduced in 1920 and had a strong impact especially on poets. A group of artists founded MAVO in 1923 with publication and activities that encompassed a wider field including art, design, theatre, architecture, among others. Surrealism was introduced in late 1920s by poets, theorists and artists including Shuzo Takiguchi, who later led Jikken Kobo (Experimental Workshop) in the postwar period. In music jazz, French chanson and European classic music were popular numbers for gramophone and radio. In less than half a century since Japan opened its border to the world with Meiji Restoration and launched an accelerated modernization, Western culture was already integrated in urban life.

However, the occupation of Manchuria in 1931 and invasion to China that followed put an end to the liberal and international atmosphere. By 1940 cultural figures who were active abroad including the painter Taro Okamoto were forced back to Japan. In 1941 Takiguchi and a Surrealist painter Ichiro

Fukuda were arrested for a groundless suspect that avant-garde artists were involved in the international communist movement. Any cultural activities that looked “western” would be considered suspicious. In the daily life use of English was banned, as well as listening to British, French or American music. Painters -- both in Western style (yo-ga) and Japanese style (nihon-ga) – willingly or reluctantly painted war propaganda. As war situation got worse metal objects – anything from statues and temple bells to “unnecessary” machines, toys, kitchen utensils, etc. - were collected to be recycled for army use. Women and children were trained to fight using bamboo spears. To compensate the lack of arms and daily commodities the authority promoted the idea of superiority of spiritual strength over material power.

When the war ended in 1945 with two atomic bombs that exploded over the cities of Hiroshima and Nagasaki, it was natural that awe for the power of science and technology came back, with a hope to catch up the world standard. New companies emerged right after the war founded by engineers who had fresh ideas that could not have been realized during the war. Sony, for example, was established in 1946 and its products played an important role in avant-garde art. Japanese love for technology is a widely known cliché, but in fact curiosity for new things among Japanese had been reported by foreign visitors over centuries.

JIKKEN KOBO (EXPERIMENTAL WORKSHOP, 1951-1957)

Without doubt Jikken Kobo was the most experimental and technologically advanced group of artists in the 1950s Japan. Aforementioned Shuzo Takiguchi played a leading role both as a theorist and a poet in re-launching contemporary art, attracting young artists, poets and composers around him. Consequently Jikken Kobo was formed in 1951 with a multimedia ballet performance titled “Picasso, le Joie de Vivre”. Inspired by a painting by Picasso, the stage set was designed by Shozo Kitadai and Katsuhiko Yamaguchi, costume designed by Hideko Fukushima, music composed by Hiroyoshi Suzuki and Toru Takemitsu, lighting designed by Naotsugu Imai - - as a collaboration of major members of the group. The choice of ballet as a form of collaboration was an homage to Dada’s and surrealist’s experimental ballet, from Francis Picabia, Erik Satie and others in 1920a to Jean Cocteau and Diaghilev, and further to American avant-garde scene with John Cage and Merce Cunningham. Helped by Takiguchi’s career and his worldwide network experiments by Jikken Kobo paced up with international movements in art.

For a self-taught composer Takemitsu who was severely rejected from the academic world at a competition the year before, Jikken Kobo was a place for unlimited experiments and multidimensional activities. Takemitsu became one of the main composers of the group and collaborated with other members such as Katsuhiko Yamaguchi for experimental theatres and performances.

Musique Concrète, which was originally developed by Pierre Schaeffer around 1950, was brought to Japan in 1953 by Toshiro Mayuzumi. Mayuzumi had graduated from Tokyo University of the Arts and studied at Conservatoire de Paris the year before. The new form of music based on magnetic tape recording technology was brought to the next level immediately by Takemitsu and his collaborators at Jikken Kobo. They expanded the concept of Musique Concrète to an audiovisual form that integrated latest electronic audiovisual technology of the time, rather than purely musical experiment. Sony’s Automatic Slide Projector system was just introduced as an educational device to synchronize a slide projector and a tape recorder. Combining Musique Concrète with slides created by artists and photographers, Jikken Kobo produced several “Auto Slide” works in 1953 with surrealistic imagery such as “Adventures

of the Eyes of Mr. Y.S., a Test Pilot” (composition by Katsuhiro Yamaguchi, music by Hiroyoshi Suzuki). The system was offered by Sony and the artists worked at Sony’s studio.

The incredible quickness with which Jikken Kobo artists grasped the possibilities brought by these new reproduction technologies and developed a new form of creation must be understood within the social context. An interest element in their activity is the combination of European and American influences. While Takiguchi In addition to aforementioned atmosphere of the era and a longer tradition of appreciating technology and new things in Japanese culture, the academism in art had not recovered yet. The fact that the major part of Jikken Kobo members did not have academic background probably helped them to think more freely.

Jikken Kobo members continued to be involved in experimenting new ideas and technology after the group diminished in 1957 after Takiguchi’s death and played major roles in the Osaka World Exposition in 1970, although it does not mean that they embraced technology without criticism. Ambivalence was felt widely among artists who had experimental approaches as in case of Osamu Tezuka who named his major robot character “Atom” (Astro Boy outside Japan) postwar Japan. Yet, as the title of the book “Robot Avant-garde” by Yamaguchi (1985) suggests, their curiosity toward technology and experimentalism shared by the Jikken Kobo members founded a basis for Japanese media art today.

PAINTING BY MACHINE

The Gutai artist Akira Kanayama is less known compared to his partner Atsuko Tanaka, the artist known for her “Electric Dress (1956), although the original use of technology and interest in materials that had not been traditionally used in art were shared among them. Kanayama helped Tanaka in realizing her ideas that involved technology such as her piece “Work (Bell)” (1955). Kanayama’s “Work” series produced mostly around 1957 involved a remote-controlled car with paint tanks he built himself, modifying a toy car. Kanayama tested a variety of crayons, markers, black and color ink with which the car scribbled or dripped while moving on large pieces of paper and later on white vinyl sheets, which he found the most appropriate for his purpose. While the artist operated the car on a sheet laid on the floor, its trajectory and the resulting traces of ink were never under the perfect control of the artist. Instead of directly employing one’s own body, as in case of other Gutai artists such as Kazuo Shiraga and Saburo Murakami, Kanayama used a mechanical medium and chance operation to draw lines. His use of plastic inflatables and footsteps on vinyl sheets in other works also suggest his positive interest in new materials, and mediated representation of body. However, when Gutai was “discovered” by the French critic / art dealer Michel Tapié and internationally introduced, these features of Kanayama’s works were disregarded. It is said that his “Work” series was interpreted as alike of Jackson Pollock’s “all-over” style in the art world outside Japan, neglecting the interesting questions that arose about originality and the role of technology in art.

Eventually Gutai artists including Tanaka shifted to “paintings” rather than three-dimensional works involving unusual medium. By the time when Gutai was invited to participate the 1970 World Exposition in Osaka, Kanayama and Tanaka left the group.

DOMESTIC AND INTERNATIONAL, POLITICAL AND NON-POLITICAL

It has been considered that the isolation from the international art world during the first years after the war helped giving birth to original and often extreme approaches by Gutai artists and by those who submitted to the annual Yomiuri Independent exhibition[1949–1963] including Neo-Dada artists. While the role of isolation was more obvious in case of Kyushu-ha, which was notorious for their wild junk artworks that contributed in putting an end to Yomiuri Independent, there existed multiple channels of information on movements in art.

Taro Okamoto, who had lived in Paris before the war and achieved recognition among surrealists and abstract painters, was most influential among the young postwar Japanese avant-garde artists. Okamoto's knowledge and understanding on avant-garde art combined with his interest in Japanese prehistoric Jomon sculptures created a complex effects on young artists, together with his Polarism (taikyoku-shugi) that regards contradictory ideas as the source of creation. Jiro Yoshihara, who founded Gutai in 1954, had access to the international art world, and communicated with his friends from the prewar period. Aforementioned Takiguchi kept communication with surrealists including Andre Breton、Marcel Duchamp, and László Moholy-Nagy. As Duchamp and Moholy-Nagy moved to the United States, Takiguchi's spectrum widened to the latest art movements in America. Another information source for some of the young artists including Yamaguchi was the library of the Occupation Force in central Tokyo. The library was open to everyone and had books on contemporary art. Using the still brand new LP record player, contemporary music was also presented. When America, especially New York, was becoming the center of the most experimental movements in visual art, music, and dance, such up-to-date information flow no doubt provided a ground for Tokyo-based artists and composers. It was missing from artists in other regions such as Gutai.

Another important issue in postwar art was politics. As the reaction to the wartime totalitarianism, movement for democracy and influence of communism widely spread, involving young artists. Struggles took place as the US government changed the policy before the end of the occupation and started oppressing leftist movements. The conflict continued in a greater scale in 1960 and in 1970, when the Treaty of Mutual Cooperation and Security between the United States and Japan was to be signed.

TECHNOLOGY AS A MEDIUM OF ART

What seems to be in common among artists such as Akira Kanayama, Atsuko Tanaka and Katsuhiro Yamaguchi is the conscious distance they kept from being trapped in domestic value system, and certain "coolness" in representing their concepts. Instead of being involved in "Japanese" aesthetics or local (i.e. Japanese) politics, or creating artworks that radiate strong messages, they used technology as a medium through which their ideas could be observed and enjoyed by others. Yamaguchi's "Vitrine" works offer different colors and patterns according to a viewer's position and movement. Kanayama's "Work" series is a whimsical experiment with a toy radio control car, which was an extremely popular hobby object of the time. By placing technology as a core part of their works, they opened up a new approach in art, consciously or unconsciously connecting the long tradition of "technology as entertainment" in Japan, and media art to come.

ENHANCING SPATIAL EXPERIENCES THROUGH DIGITALLY AUGMENTED SPACES:

Serhat Kut, Semra Aydinli & Arzu Erdem

This article will be discussing Augmented Reality in a trans-disciplinary approach to discuss the possibility of enhancing the experience of space through our bodies by augmenting it digitally in a 3d setting. The article will be searching for how could the experience of space enhanced digitally in terms of body-space interaction and what might be the consequences of this change.

Introduction

It has been two decades since Weiser had put forward the vision of Ubiquitous Computing in which he was foreseeing the shift away of computing from a desktop centered state towards a pervasive computing with smaller mobile devices distributed throughout the space (Weiser 1991). Today this vision is being realized with the emergence and pervasive use of tablet devices and smart phones connected wirelessly to public or private networks and each other as well. And supporting this vision, wearable computers and head mounted displays (HMD) has been much more accessible for end users in terms of price and ease of use.

The 1990s has been the era of virtual reality and most of the discussions in economy, politics, architecture and urban design theories were focused on the notion of cyberspace experience. However among the emerging new media and digital interaction technologies the Augmented Reality (AR) technology

enabling to overlay the digital information over the physical space is turning back the discussion on the physical space again. But this time a physical space which is augmented with dynamic digital media.

Cybertectonic Space

The term Augmented Reality is broadly being used for the Computer Vision technology which enables overlaying 3d registered digital dynamic media on physical space (Azuma 1997). But on the other hand in a wider perspective, in terms of spatial experience, any situation enhancing, transforming or manipulating our experience of space may be understood within the context of Augmented Reality. Emphasizing this point of view Manovich brings up the concept of Augmented Space, re-conceptualizing augmentation as an idea and cultural and aesthetic practice rather than as a technology (Manovich 2006).

In this perspective Augmented Space may be considered as a new space or transformation of the physical space with digitally overlaid data and even as a new realm providing a place for Being-in-the-world (Heidegger 1978). In another terms Augmented Space is a new realm containing virtual elements in a real physical space. Here reality and virtuality are not considered to be opposite concepts but they are viewed as lying on the opposite sides of the reality-virtuality continuum (Milgram et al. 1994) where Augmented Reality is located somewhere in-between.

Regarding McLuhan's perspective involving media as an extension of human body (McLuhan 1995) Augmented Reality can also be discussed as a new medium extending our bodies and therefore providing new possibilities of space experience. And from now on to pull back the attention from the computer vision technology to architectural domain, the new in-between space experience made possible by Augmented Reality will be called as cybertectonic experience, coining the words cybernetics/cyberspace and architechtonics. And the new space produced via cybertectonic experience will be called as cybertectonic space.

Within this context it might be concluded that Augmented Reality is not just a Computer Vision technology providing possibilities for overlaying digital media on physical space but more than that Augmented Reality is a concept strictly related with spatial experience and bodily perception and therefore in an ontological perspective it provides a new in-between place in the continuum of real and virtual and thus resulting a new problematic domain in Architecture that should carefully be considered. This new problematic domain might be a ground for understanding the structure and qualities of cybertectonic experience and how cybertectonic space is produced.

Library+

The Library+ project is a pilot study that has been experimented with undergraduate architecture students of Istanbul Kultur University Department of Architecture at the main campus library. The main goal of the project was to create an Augmented Reality scene in the conventional setting of a library by overlaying digital information over the physical space to provide a new realm for cybertectonic experience and observe, discuss and evaluate possibilities of cybertectonic space in an architectural point of view.

The hardware used in the project was a backpack system consisting of a laptop computer and a Head Mounted Display and the open source AMIRE marker tracking based augmented and mixed reality authoring tool has been used as software. Marker based augmented reality authoring software makes it possible to get much more precisely set scenes in the physical space than gps based systems and yet easier to install and setup compared to RFid tag based systems since the only thing needed to register any digital object in the physical space are black and white patterns printed on papers which are called markers. AMIRE, not only making possible to overlay digital data on physical space but it also allows you to design some interactive scenes according to parameters like distance of the body from the digital object, distance between two objects and markers and some logical operators like if and then. With all these parameters much more interactive cybertectonic spaces could be created and this interaction is not just pressing buttons and triggering some events more than that and most importantly the scene is interactively constructed based on body gestures and the movement in space, turning around objects, bending over and etc.

Therefore the cybertectonic library space is not only a physical space ornamented with digital media, it's a space which is open to interact with, a space that encourages bodily perception (Merleau-Ponty 1996) of the digital, which is intensively connected to or extending the physical.

Concluding Observations

We have experienced that Library+ offers a completely new library experience rather than searching the catalogs in the computers and accordingly finding the books in the appropriate shelves and reading them eventually. The space encourages one to discover the library space and reveal the hidden information between shelves or books and leading him or her to possibly unexpected results or experiences. The cybertectonic space of the Library+ changes the linear and usual process of research or reading experience happening in a library and we have also observed that the movement of the body dramatically changes in the cybertectonic library experience as expected.

Supporting the cybrid principles that Anders has mentioned earlier (Anders 2008) we have found that reciprocity between the physical and the virtual elements of cybertectonic space is an essential issue which should be undertaken as a key principle when creating cybertectonic experiences. Otherwise, the weak relationship of physical space with the digital content may prevent to create meaningful cybertectonic experiences when aiming to enhance the experience of space.

As a conclusion it could be told that Augmented Reality technology brings up a new problematic domain in to Architecture that should be discussed in terms of experience of space. The cybertectonic space is capable to change the conventional experience of space and therefore as an extension of our bodies it is letting us to have new experiences of space, leading us to get in a new ontological state of Being. With the emergence of smart phones and tablets, the concept of ubiquitous computing has the potential to create ubiquitous cybertectonic experiences and we believe that further work in architectural domain is essential to understand and interpret the cybertectonics of space.

REPUBLIC OF THE MOON - A NEW ARTISTS AUTONOMOUS TERRITORY

ROB LA FRENAIS

How will we live on the Moon? Despite long-term plans to send humans to Mars, in the short term the Moon is the most likely place to rehearse living away from the Earth. Republic of the Moon discusses possibilities for artists' autonomous solutions.

Agnes Meyer-Brandis training Moon Geese (courtesy the artist)

"Earth is the cradle of humanity, but one cannot live in a cradle forever" - Konstantin Eduardovich Tsiolkovsky, 1911

In two months time from the writing of this paper 6 people (all men) will emerge from a 'wood panelled spacecraft' at the Institute of Biomedical problems in Moscow. This will be the conclusion of Mars 500, an attempt to simulate the logistics, psychology and monotony involved in a mission to Mars. This is the most ambitious of the analogue environments that have been designed on earth to investigate the human factors in long-term space travel – previously the Mars Desert Research station in Utah has been used to rehearse life on Mars complete with space-suited expeditions from a habitat into the desert.

But it is still likely that any long-term attempt to live off the planet will be on the Earth's Moon, only 3 days away by rocket, although reachable over a longer period by electric-powered spacecraft such as the European Space Agency's SMART vehicle, eventually orbiting the Moon. So, despite long-term plans to send humans to Mars, in the short term the Moon is the most likely place to rehearse living away from the Earth. It is envisaged that sooner or later a small outpost of humans and robots will be established, possibly living in tunnels drilled under the Moon's surface and quite possibly established by emerging superpowers such as China or India on the South Pole of the Moon where water ice is expected to be found. So how might we respond to this new territory, which technically belongs to everyone?

The idea of humans living away from the Earth's regular infrastructures also gives rise to alternative thinking about issues such as sustainability, human psychological factors and governance. The recent movie 'Moon' worked on the dystopic basis that we might only wish to send clones to exploit the Moon industrially. But what if we were to apply new 'open source' thinking about collaboration between humans and technology to create a liveable solution for an off-planet habitat. Space architects and psychologists such as Regina Pelzsus (quoted below) are currently proposing new paradigms for dealing with issues such as monotony and governance and artists are beginning to propose new models for living off-world.

One strategy could be the pre-emptive setting up of a micronation which could claim the Moon independent of national or commercial interests. This strategy has already been used by artists such as Slovenia's Neue Slovenisch Kunst (NSK) who issued their own passports, the Danish group N55 or artists like Antti Laitinen. Alexandra Mir famously declared herself the 'First Woman on The Moon' on a Dutch beach. Other strategies are being proposed in the new Arts Catalyst project and exhibition 'Republic of the Moon'

The initial idea came from a recent International Astronautical Federation meeting in Paris attended by the exhibition curators, in which issues of space governance were discussed. A United Nations official with an interest in the peaceful uses of space stated at a private meeting "The last thing we want to propose is a Republic of the Moon". We wondered: why not? So we propose to set up, in advance, an artist's micronation- a Republic of the Moon and will communicate with specific artists and groups inviting them to participate, to start thinking about methods of governance, diplomacy and autonomy of this future artist's territory.

Regina Peldzsus is working with the internationally acclaimed artist and architect Tomas Saraceno to build an environment which will challenge a group of 20 volunteers to live for 20 days in a moving spherical module in which they will work, eat, socialise and sleep, but which has no 'up' or 'down' at any one time.

Saraceno, who has created the major exhibition 'Cloud Cities' currently showing as a one-person show in the main hall at the Hamburger Bahnhof, is a latter-day follower of Buckminster Fuller, following the dictum 'There are no passengers on Spaceship Earth, only crew'. His installation forces the viewer to become a participant in a different way, raised above the ground in semi-stable inflatable structures and become a physical metaphor for collaboration.

Peldzsus has written a short summary of the objectives of such a project:

"The conditions in an isolated and confined environment such as a Moon base pose a range of psychological challenges to a group of astronauts. In terms of crew cohesion – which is vital for both physical and emotional survival in a hostile and remote location – this can include social monotony, clique building, personal withdrawal and aggravation of interpersonal tension. [1, 2] Leadership becomes a crucial concept in ensuring harmonious and successful co-habitation [3] and, in a broader sense, represents or challenges models of governance on Earth.

As a central part of the programme of Republic of the Moon, a simulation of a Moon mission is proposed. It involves three groups of participants who help design, man and operate the base for the dura-

tion of the exhibition. A DIY Lunar Base will feature all necessary habitability aspects such as sleep stations, galley, windows, greenhouse, hygiene facilities, storage room, work lab, space suits and maybe even an exploration vehicle.

Space analogue studies and ground simulations are an essential – albeit expensive – component of research activities in the scientific spaceflight community. In the light of future long duration missions, space agencies and independent institutes around the world are preparing. Examples include the Houghton Mars Project in the Canadian High Arctic, the Mars Desert Research Station in Utah (US), ESA's Concordia Research Station in Antarctica, and – most notably at the moment – the MARS500 simulation study at the Institute of Medical and Biological Problems in Moscow.

Staging a simulation in the framework of Republic of the Moon will not only deliver insights and firsthand experience to the participating audience, but inspire and inform a wider public on human aspects of long duration missions."

A different approach to the Republic of the Moon project has been that of the artist Agnes Meyer-Brandis, whose poetic-scientific investigations weave together fact, imagination, storytelling and myth, past, present and future. Her project 'cloud-core scanning' involved research taking samples from the centre of clouds in to zero gravity in a parabolic flight in order to test how they behave.

Meyer-Brandis weaves a narrative based on writings by Francis Godwin based on an excerpt from the book *The Man in the Moone*, written by the English bishop Francis Godwin in 1603. Godwin was the first person ever to describe weightlessness – long before Newton's theory of gravity. The protagonist in the book flies to the moon in a chariot towed by gansas birds, more commonly known as geese. These special moon geese migrate every year from the earth to the Moon.

Meyer-Brandis has actualised this concept has by breeding 11 geese at the artists residency in Pollinaria, Italy - imprinting them on herself as goose-mother, training them to fly and taking them on expeditions. All these geese have been named after famous astronauts and she is proposed to build a Moon analogue habitat for them in Southern Italy which would be operated, in the same way as human analogues, from a remote control room in Northern Europe as part of the Republic of the Moon project.

The context of many of these artists interventions reflecting on a moon colony is inspired by other projects that attempt to take on 'big' infrastructures such as the space industry and bring them down to a human-sized level.

In 2010 a workshop and conference was held at Newcastle University and the AV Festival to examine artists autonomous infrastructures in the light of a potential 'planetary breakdown' Following Helen and Newton Harrison's notion of the 'Force Majeure – that we should be preparing for different forms of governance following radical blows to the existing infrastructures by inevitable climate change – Autonomous Infrastructures looked at the many models created by artists and by communities of people operating semi-autonomously in society in intentional and utopian communities. It examines the symbolic nature of many of these initiatives and propose the future realisation of unrealised artists infrastructures. One of the projects coming out of this was the Train project by hehe, which although not part of Republic of the Moon, symbolised the approach to the subject.

The artist group hehe (Helen Evans and Heiko Hansen) uses minaturisation as a method of playful nuanced critical intervention and reflection around issues of sustainability, such as their recent work in Cambridge during 'Invisible Dust' and at Ars Electronica 'Is There a Horizon in the Deep Water?', which re-enacted the BP Oil Rig disaster on a small scale in a pool of water.

The Arts Catalyst is currently working with them on a long-term research project called Train, which takes the problem of locomotion as a starting point. The project develops autonomous one-person vehicles that operate temporarily, in the form of a performance, on unused or abandoned rail tracks. An example of such a "dislocation" is the vehicle Tapis Volant (Flying Carpet). The Flying Carpet, which runs along the historic tram track in central Istanbul, appears as a soft red cushion with beaded tassels dangling down from each of its sides, large enough for one person to sit comfortably. It runs along a tram track, using one of the rails as a monorail, it's wheels propelled by an electric motor. Underneath the cushion is an electro-mechanical system that allows the rider to advance whilst seated in a cross-legged posture. This body position not only mimics the way of sitting on a mythical flying carpet, but also gives the body a different inclination and state of mind, suggesting that that rider has to be grounded and balanced to ride this particular vehicle. In this project they use their indirect comment on environment to the issue of public transport versus the apparent freedom of the motor car.

Hehe has made a widely publicised work call 'Nuage Vert' or Green Cloud, in which factory emissions are monitored and dramatised by a live interactive laser illumination of the shape of the smoke emitting from a factory in Helsinki, and most recently an incinerator in St Ouen, Paris. While not directly taking on issues of space exploration, hehe's approach is an example of the symbolic power of artists intervention into large-scale infrastructure such as the space industry.

Space exploration is also too often seen to be the province of the US, Russia and Europe. But the some of the most recent launches have been from India, in the Chandrayaan programme. Rakesh Sharma, India's first astronaut, said that India was embarking on Moon exploration in order to be part of the conversation of the future of the Moon. "But who is part of that conversation, where does it happen, who is excluded and who ever hears it?" asks Joanna Griffin, who with artists from Srishti School of Art in Bangalore along with interested scientists from the Indian Space Research Organisation (ISRO) are creating an open forum where meanings of the moon in culture and meanings of the moon to scientific projects, can be discussed, in the project Moon Vehicle.

Moon Vehicle will look at what is discussed in relation to the Moon in order to transport points of view – commonality and difference. To demonstrate to the small community deciding the future of the moon that they have responsibility towards cultures they do not know. The project is conceived as a perspective-altering exercise. The live image of the Moon will be projected from a telescope onto the ground, creating a new poetics that encourages people to think about the relevance of the Moon to our lives and the earth in new ways. It is a performance space, a storytelling space, a play space and a debating space Joanna Griffin: "It's been a way to bring people into a circle to talk about the moon. It does this really poetic thing of 'earthing' the moon so you look down instead of up and think differently We've tried to bring people from different walks of life to talk about the meaning of the moon to them. We've tried to have it as something non-hierarchical, so not just about 'experts' It's something kids absolutely love to play in."

So why this moon? And why humans? Andy Gracie, working on a project for a different moon that that of the Earth- Titan, the Moon of Saturn. His idea is to use DIY and bio-hacking approaches to creating the

atmosphere of that moon here on Earth, using everyday materials such as vodka and a bicycle pump and breed fruit flies in this environment to see if they would survive.

Gracie describes the project here: "The fruit fly *Drosophila melanogaster* has been used as a model organism since early 20th century and more recently has become a workhorse of space bioscience, having flown in biosatellites, space shuttles and space stations. Due to the 75% similarity of the *Drosophila* genome to our own, a range of experiments on this organism continue to inform us about the effects of radiation, microgravity and other space environmental factors on ourselves. Out of a wide range of experimental organisms it is the fruit fly which will arguably provide most of the data on how the human is expected to adapt to off-earth conditions.

Many scientists view Titan as an analogue to the early Earth, although the temperature is significantly lower. Some theorists cite Titan as a possible host for microbial life, or at the least as a prebiotic environment rich in complex organic chemistry. Anomalies in the methane cycle within Titan's atmosphere are identical to confirmed life signs from terrestrial microbes.

The selection criteria for astronauts has commonly and famously been based around the idea of 'the right stuff' – or in other words the candidates having the correct combination of attitude, lifestyle, physical prowess, political views and so on. There is also the strong connection to the military as a pool for candidates, despite the fact that scientific accomplishment is beginning to be seen as an additional virtue. Would the selection procedure for *drosophila* be in any way similar to the selection procedure for human astronauts? Would they be selected for their physical properties and attitude or according to more familiar and endearing traits. When would be the right time to send the first female *drosophila* into space?"

While we see the Fruitflies on Titan project as an interesting and provocative addition to the Lunar Analogue environment that would be at the Centre of Republic of the Moon, Andy Gracie's stark comments on selection are exactly what we will question in terms of thinking of who might live in a Moon colony.

We are humans, not fruit flies! Astronaut selection for Apollo, the Russian space programme during the Cold war are exactly what we regard when thinking of space travel as limited to those with the 'right stuff', exemplars of the top-down command-structures military paradigm that powers wars. By bringing artists into the equation, particularly those familiar with collaborative methods of working, can we redefine living governance and team behaviour in extreme circumstances in terms of collaboration, knowledge-sharing, consensual decision-making and multicultural approaches in rehearsing for, then living on the Moon? Or would it revert to Big Brother-style survival of the fittest? Republic of the Moon sets out an artist-driven manifesto that perhaps points out some alternatives for living and working in space.

(The Republic of the Moon project is a collaboration between The Arts Catalyst, London, FACT, Liverpool and other European partners taking place in 2011-2014)

OPEN DESIGN PRACTICES + WEARABLES + 3ELECTROMODE

VALÉRIE LAMONTAGNE

This paper investigates open design strategies within DIY wearable practices and the collaborative initiatives of 3electromode and other design collectives in the field of fashion and technology. It looks at how technologies are facilitating access and small production lines in the changing creative and production practices of fashion and technology—from an industrialized vs. craft-based one—to a high-tech, hybrid, networked cottage industry.

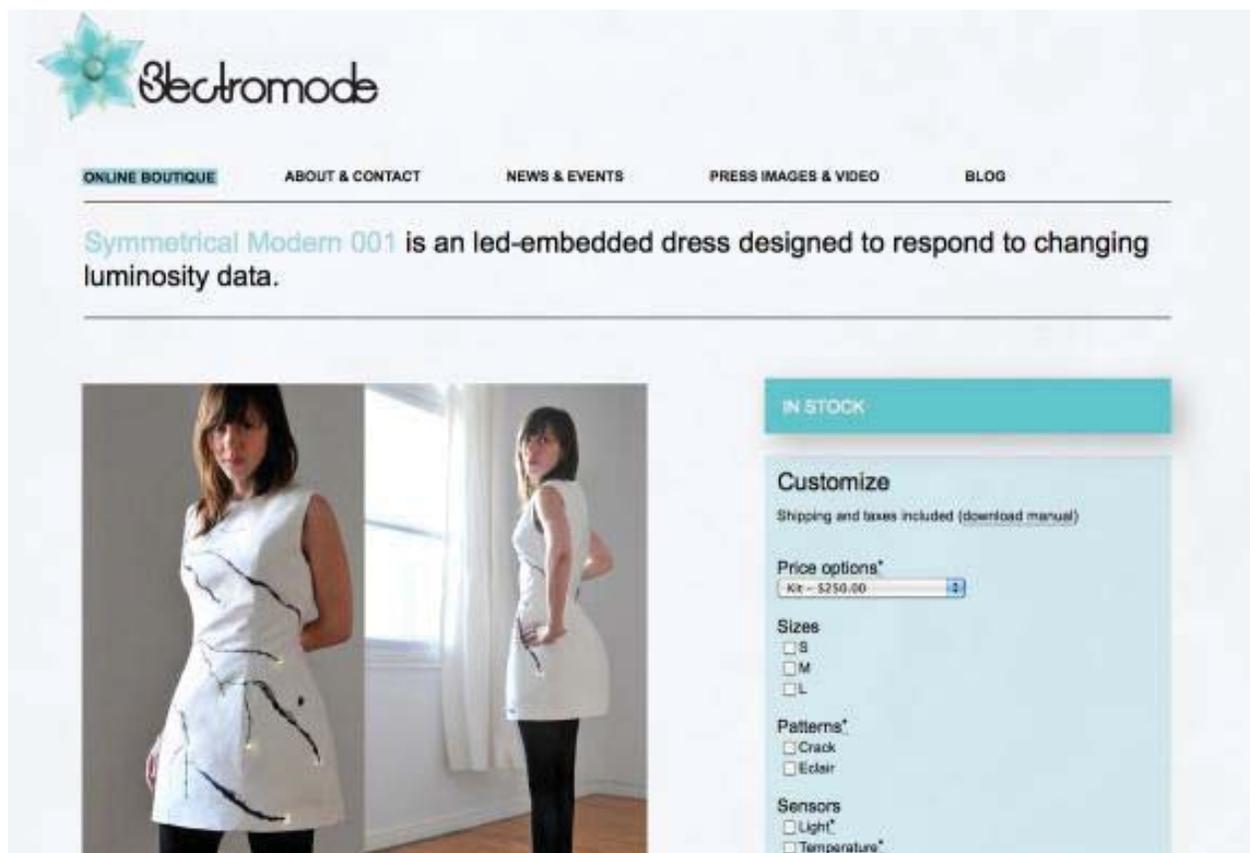

Fig 1. © 3electromode website

Fig 2. © 3lectromode Asymmetrical Modern 001 (detail)

Fig 3. © 3lectromode Symmetrical Modern 001 Éclair

What is Open Design?

OPEN DESIGN IS ABOUT MAKING.

Open design is about making—it is about innovation in methods, materials, practices and technologies which are experimented in a hands-on, experiential, trial and error fashion. It is a practice invested in giving people the means to make things they could either have not made on their own or previously (because of lack of knowledge or access to technologies and methods) or would not have made on their own or previously (because of lack of exposure to the potential of new technologies, designs, materials and methods). Open Design is about tangible—material—dreaming. It is also about democratization of fabrication methods, aiming to include makers and users with no minimum experience standards, save lack of ideas or persistence. Open Design is also about a willingness to get your hands dirty, ask questions, mess around with materials, and question and contribute to ideas already in the air or literally on the table. Open Design is not so much about success or failure, but more about the process, about the relationship between ideas, people, machines and materials and how they come together to create a “thing”.

OPEN DESIGN IS ABOUT ACCESS.

Open Design is about access—it is about putting the means, knowledge, techniques, technology and materials needed to make things easily accessible. Much of this access is done via internet culture promoting practices, tutorials, and information on where to find materials and services. Sites such as Instructables and Craft, featuring a wide range of technology and craft-based tutorials, are places to go to find materials and methods. Other websites such as Open Hardware and Thingiverse share files for the emergent and growing practices of 3D printing and other forms of machine-tooled and 3-dimensional object making. While tangible meeting and working sites, Fabrication Laboratories (or FabLabs), such as ProtoSpace (Utrecht, Netherlands) and Open Design City (Berlin) as well as Hackspaces such as c-base (Berlin) have made a significant change in the availability of access to machines such as 3D printers, laser cutters, and contact with a community of technical and computational experts. Of course, festivals, fairs and events such as MakerFaire, SIGGRAPH, SXSW, Transmediale (Berlin), FutureEverything (Manchester) and ISEA provide great opportunities to share knowledge, skills, and meet the actors involved in the global shift of sharing design expertise.

OPEN DESIGN IS ABOUT COMMUNICATION.

Open Design is about communication—it is a practice heavily reliant on documentation—video, photo, illustrations etc.—and the vulgarization of technical language leading to the simplification or elimination of specialized jargon. It is important that design concepts and methods be easily understood, communicated, modified and shared across platforms and knowledge bases. Without the ability to communicate practices, Open Design would perish. Open Design is about community, hence it is about the accessibility of information, knowledge, practice, tips, and knowhow—which would be impossible without shared language. It is about creating interactive relationships between makers, designers, and technicians, which can be interpreted over a broad range of experience and interests. Think of Open Design as a communal soup, which is expanded, modified, corrected, and enhanced over time—but always accessible. As long as we can follow the tread / information / instructions we can all participate.

OPEN DESIGN IS ABOUT SOCIAL ADAPTATION.

Open Design is about social adaptation—it invites initiated and uninitiated users to reproduce, modify, improve, customize—and be inspired by others and their work. It is about co-creation, and ‘personal design nodes’ where the shape and making of design can be seamlessly personalized, and adapted to use, whimsy, or even unforeseen practical solutions. It is both about the personal and the collective in as much as it solicits input from individuals for their needs and desires while also keeping the practice and knowledge open-ended enough for collective contributions and specializations over time. Works such as Nervous System’s user-generated, nature inspired jewelry propose new and exciting design collaborations where the results unexpectedly unfold. Open Design stresses for adaptability on the material front (easily modified techniques and technologies) and the social front (easily personalized, accessed and interpreted designs) in order for it to remain conversant with future designers. Open Design is a future forward practice, which factors in social adaptation for processual design iterations.

OPEN DESIGN IS FREE!

Open Design is free—because making it free permits it to travel far and wide, gain exposure, be critiqued, improved through stylistic as well as technical corrections, additions and modifications, pushing the discipline forward. And if others give it away, so can you. It does not mean that you cannot make things, sell them, or get paid for what you do—but rather that key information, practices, and materials that contribute to the making are either distributed or rendered physically accessible for free in a belief that, sharing makes for better design, and better communities. An example of this economy of Open Design is Ronen Kadushin’s Hack Chair, wherein the designer made all of the chair’s DXF files available for download, copying, re-use, and interpretation. The only parameter implemented was that if a new iteration of the Hack Chair was marketed and sold, profits would be shared with the original designer. The Hack Chair and its concept has led to a series of exciting and unscripted design iterations, collaborations, and exhibitions for Ronen Kadushin. This ‘free’ practice is predicated on the Creative Commons structure, which also allows for a spectrum of copyright attributions and uses which can be adapted to different production and cultural artifact contexts.

What can Open Design do for wearables?

UNZIPPING WEARABLES

Open Design for wearables democratizes and ‘unzips’ the practice, making it more accessible from a variety of angles, needs, technologies and visions. Wearables is a wide ranging practice as it stands, combining engineering, fashion design, craft and technical production methods as well as artistic expressiveness and computational know-how. With such a variety of input points and expertise angles, Open Design serves wearables by making the divergent axis communicate with one another, share knowledge, skip over technical jargon and schematics and create a platform that is richly and widely interpretive for many users and many uses.

SITES OF OPEN DESIGN IN WEARABLES

Sites specializing in e-textiles such as *How To Get What You Want* run by Mika Satomi and Hannah Perner-Wilson are a wealth of information on techniques for creating soft circuit designs while publication such as *Fashioning Technology* by Syuzi Pakhchyan (which now runs as a wearables blog and networking site) give numerous concrete examples are ‘recipes’ to create your own D-I-Y electronic garment or object. The recent *Open Softwear* publication on which Melissa Coleman collaborated also expands on the technical practice of wearables by untangling information around its production. Finally, real meeting points such as Otto von Busch’s *Hacking Couture* workshops and the *E-Textile Workspace* run by Piem Wirtz and Melissa Coleman at V2_ Institute for the Unstable Media (Rotterdam) give an interested or active public a forum to share information and get tips on practical issues, and conceptual developments in the field of wearables.

All of these sites, publications, and locations dedicated to wearables operate on limited or no funds, and are in principal free (or almost free) of access. Though perhaps not self identified as Open Design, they are certainly conceptually and practically oriented towards it. What is more, they seamlessly converge with and contribute to Open Design websites, spaces and practices previously mentioned, adding to the distributed network of knowledge and practices.

TRANSFORMATION OF WEARABLES VIA OPEN DESIGN

What we see with this increase in access to knowledge, spaces, technologies and practices is a professionalization of the wearables field. Previously craft or technical-only niche groups are becoming increasingly conversant with one another. Access to high-tech tools and experts are ‘industrializing’ the practice giving designers more options to professionalize their craft through custom circuits, 3D printing, laser cutting etc. The technical networks, both tangible and conceptual, help shape this hybridization of the wearables field by giving designers access to specialized knowledge and tools, resulting the expansion of their material repertoire and craft expressiveness. Fashion designers such as Pauline van Dongen have collaborated with 3D printing company Freedom of Creation to create 3D printed shoes, while Anouk Wipprecht has collaborated with wearable art labs such as V2_ to develop interactive garments. Meanwhile, Moon Berlin, a fashion label exploiting light in their designs, has combined the best of fashion with the best of technology by collaborating with the Fraunhofer IZM and incorporating their state-of-the-art stretchable circuits. All of these wearable designers are tapping into expertise and tools which are distributed in an increasingly open and free spirit.

The results of this open exchange is the emergence of an increasingly high-tech, hybrid, networked cottage industry in which fashion knowhow and electronics innovation are being merged in a professional yet highly democratic fashion culture and community. Though the overlaps come from at times divergent technical and artistic fields as well as economies, the push is, as noted in the Creative Common’s recent anthology of interviews ‘The Power of Open,’ a solid argument for “sharing becoming a default standard”. This is a revolutionary moment for the making of wearables and 3D objects, similar to that which occurred in the 2D world of desktop publishing in 1985, which we should embrace, share, contribute to and protect via Open Design philosophies and practices.

Open Design + 3lectromode

DEMOCRATIZED, AESTHETICIZED, AND PERFORMATIVE

I want to take this opportunity to speak about my own involvement in Open Design, via the 3lectromode platform. 3lectromode holds the vision of innovating in the field of wearables by combining technology with customizable prêt-a-porter fashion. We aim to inspire a future where wearables are democratized, aestheticized, and performative. We are a small design group interested in developing accessible wearables which combine D-I-Y technology with current fashion research. We are fascinated with the potential for technology to create new modalities of interaction between the body and its environment, and are interested in the performative potential of technology.

OPEN KITS + USER-INPUT

Key to 3lectromode's design ethos is a to create a library of open sourced fashion designs which can be easily assembled as kits by anyone with an interest in wearables, electronics or fashion. The kits come complete with the printed garment, necessary electronics and instructions, taking the guesswork out of electronics assembly while permitting the user to create a customized and fashionable design.

Designs are printed on textile printers on which also include the layout of electronic schematics and sewing directions. The methods for assembling the electronic components of the wearable are integrated into the design and can be visually followed much like a painting by numbers, without interpretation or recourse to manuals. Each piece is uniquely designed, and comes with customizable options for different print patterns, colours, models, and sizes - giving the user-end designer agency in creating his or her own iteration. Computational variations are also included to modify LilyPad Arduino program. So far, the designs with 3lectromode have focused on integration of LEDs with various sensors, utilizing the LilyPad Arduino platform for electronic components and programming.

3lectromode's kits are the perfect entry point into wearable technology because of their graphic visualization of electronics assembly methods, while also creating a uniquely stylish and fashionable garments. In the process of testing out this Open Design platform, we at 3lectromode have been interested in integrating feedback from the user-end designers and welcoming collaborations on the sharing of techniques, designs and applications. Ultimately, while keeping a stylistic curatorial vision true to 3lectromode, we are interested in seeing how people might hack and interpret our work in an Open Design fashion.

TELE_TRUST FOR NETWORKING BODIES

Karen Lancel

Lancel & Maat explore our perception of augmented 'reciprocity', 'presence' and 'trust'. In an iterative research process they match theoretical insights with experiential data in a series of artworks, designed as 'Social Labs' in smart city public spaces. Experimenting with tangible interfaces and participatory systems, new insights, innovative technologies and the human body meet to inspire (yet) unimaginable types of engagement.

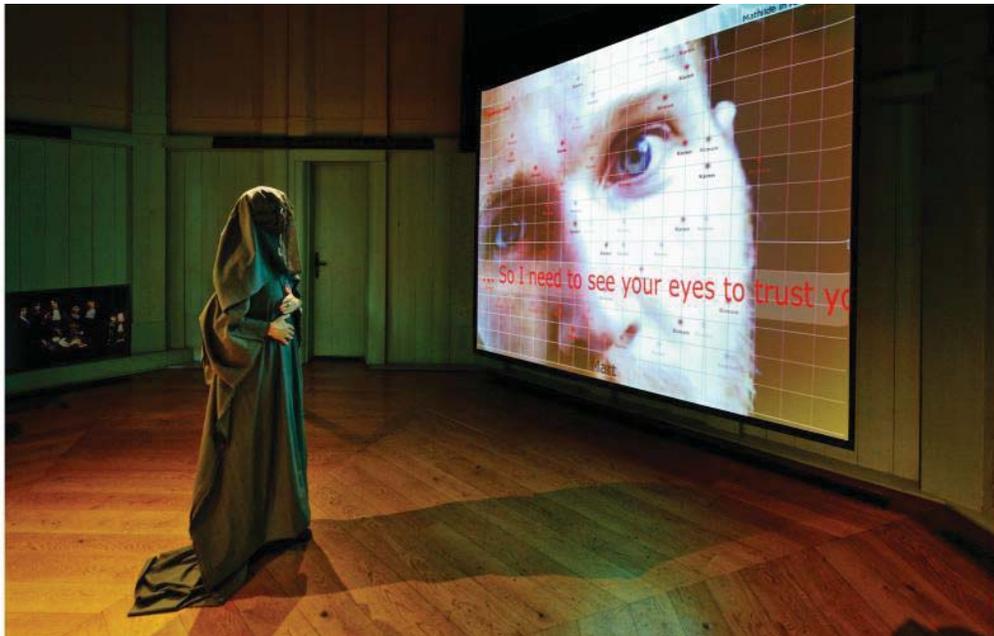

Fig 1. Tele_Trust, 2010, Lancel & Maat, photo by Pieter Kers. Location: Waag Society for Old and New Media Amsterdam. The 'DataVeil' is a smart textile wearable tangible interface connected to a free smartphone app; for an intimate networked body experience. Audience members wear the DataVeil.

Fig 2. Saving Face, 2011, Lancel & Maat, Photo by Maat/Lancel. Performance Installation 'Saving Face' is a smartphone app connected to networked urban screens. The smartphone app functions as a 'touching-body-scan'; with which one can create together a non-controllable composed 'networked identity' through the act of touching and caressing one's intimate face. Development with the Waag Society for Old and New Media Amsterdam and Dutch Media Fund.

Fig 3. Tele_Trust, 2010/2011, Lancel & Maat. In Festival 'ElectroSmog', photo at BNMI Canada. Six Tele_Trust DataVeils are networked through an online database and smartphones in three different public spaces and time zones: Netherlands, Canada; New Zealand.

'I am part of the networks and the networks are part of me...I link, therefore I am. '[1]

How do we trust each other as networking bodies?

In our contemporary networked society, interaction increasingly takes place through wireless, social networked media. The possibilities of tele-presence have made place and distance irrelevant for the experience of social proximity and allow 'networking bodies' to be present at several locations, temporalities and social settings at the same time. At the same time the public space turns into a 'smart environment' that increasingly interacts with the electronically and digitally enhanced body. These developments cause profound changes in the role of the body and physical presence since mediated presence leaves little or no room for touch, face to face encounters, and body language that are core components for the building of trust and reciprocity, which are in turn the foundations of social structures.

Tele_Trust is a research into how in mediated and tele-present society bodily based experiences of presence, reciprocity, and trust can be generated, mediated and maintained. It is a critical and sensitive exploration in how we can intensify networked affective experiences in relation to the mediated body. It looks for new forms of interaction, participatory and multi actor systems and interfaces, in which the conditions for 'reciprocity' and 'trust' can be recognized and acknowledged or differently perceived. In Tele_Trust new insights, innovative technologies, and the human body meet to initiate and inspire (yet) unimaginable types of intersubjective engagement.

Tele_Trust is an inter-disciplinary research. It is developed, tested, shown and published in collaboration with universities and (art) academies; tech-labs and media institutes; in museums, festivals and conferences. It is an iterative research process in which theoretical insights are matched with experiential research data:

A. *Theoretical context.* The theoretical context includes media-theories emphasizing the central position for affective and receptive sensory processes in the body experiencing the world - and perceiving the other. Among others it relates to texts of Donna Haraway, Caroline Nevejan, William J. Mitchell, Michel Foucault, Paul Virilio, Mark B.N. Hansen.

B. *Art works - 'Social Labs'.* The experiential research takes place in art works designed as technically smart 'Social Labs' in dynamic public spaces. For these 'Social labs' Lancel and Maat deconstruct existing social interaction models and subsequently reconstruct them into new models for semi-compatible multi-actor systems. They build on these systems because through the gap of incompatibility they experience a drive for creative, audience engaged experiment. The social labs develop as follows:

1. Firstly parameters for designing networking body presence and body proximity are distilled from theory and translated into model-drawing and 3-d maquettes.
2. This leads to the development of a series of 'Social labs', containing networked wearable devices and bio-interfaces. Examples of these 'Social Labs' are 'Tele_Trust', 'StalkShow' and 'Saving Face'; visible on <http://www.lancelmaat.nl>.
3. The 'Social Labs' provide the context for obtaining research data; through the networked devices and interfaces we test parameters for networked body presence and trust. With participants we discuss their experiences, perception, needs; and their gained physical, spatial and social knowledge. The 'Social Labs' take place in various social geographical cultures.

4. 'Social labs' participants contributions are added to a data-base and website, creating an engaging, intercultural agora on the notion of networked trust, reciprocity and presence systems.

Case Study: Social Lab 'Tele_Trust'

How do we trust as networking bodies? Do you need to see my eyes to trust me or do we need to touch?

The social lab Tele_Trust is a performance installation. It creates an engaging agora researching new parameters for online trust. In Tele_Trust we are faced with a paradox: while we increasingly demand transparency in our changing social eco-system, we cover our bodies with personal communication technology. Tele_Trust it invites the audience in a semi-compatible social system for an innovative, reflective embodied encounter. In a visual poetic way, the artists research contemporary emotional and social tension in smart cities - between visibility, presence, privacy and trust.

How does it work?

Tele Trust networked performance-installation takes place in dynamic city semi-public spaces, like train station, museum, festival. Here the audience meets in an interactive DataVeil. This DataVeil is a tangible body interface for 'scanning online trust':

DataVeil.

The DataVeil is a full body covering garment, Gender neutral, and One size fits all. Its design is inspired by eastern and western traditions, like a monks' habit, a burqa, Darth Vader, and a 'trustworthy' chalk stripe business suit.

When wearing the DataVeil it functions as a second skin. Flexible, invisible touch sensors woven into the smart fabric of the veil, transform your body into an intuitive, tangible interface. It is a membrane for scanning an intimate, networking body experience:

Smartphone connected to a DataVeil.

Can I touch you now? By touching your body in the DataVeil, you meet strangers online through their smartphones. Inside the DataVeil you may be unidentifiable but before 'disappearing' your portrait is added to an online database. By gently caressing their screens, anonymous smartphone users worldwide can unveil your face online. In an intimate body experience and real time audio, you share emotions and statements of trust, about the questions: Am I here with you? Who is watching who? *Who is controlling who? In what identity and in whose body?*

Database.

In an ongoing process, user generated content is continuously added to the Tele_Trust database. With the DataVeil the artists collect knowledge about 'privacy' and 'trust' in different social-geographical cultures. Stories from different cities weave together into an exchanging narrative -

Everyone can wear a DataVeil.

Tele_Trust interactive DataVeil and *free smartphone app* are developed with V2_Lab for unstable media Rotterdam Netherlands; Banff New Media Institute Canada, Technical University of Delft Netherlands.

BUILDING ACCESSIBILITY STORIES: ENABLING MULTI-SENSORY EXPERIENCES WITHIN THE OLPC PROGRAM IN URUGUAY

Tomas Lorenzo & Gustavo Armagno

This paper shows *Enabling Stories*, a multimodal, interactive storytelling application, designed for children with physical disabilities, as well as children with normative development, that runs on *One Laptop Per Child's* computers.

Enabling Stories is a tool for stimulating the development of specific cognitive functions and skills, as well as promoting digital inclusion, and improving social, emotional and motivational aspects on its users.

A girl playing with Enabling Stories, a multimodal interactive storytelling application.

Introduction

The *One Laptop Per Child* (OLPC) program aims to provide each child in developing regions with a connected laptop to address the digital divide and to allow them “to become connected to each other, to the world and to a brighter future.” [1][2]

Uruguay, through its governmental project –*Plan Ceibal*– was the first country to achieve the ‘full deployment’ status, after successfully delivering a laptop (named XO) to every public schooled child between 6 and 12 years old. [3] The acronym ‘Ceibal’ stands for Conectividad Educativa de Informática Básica para el Aprendizaje en Línea (Basic Computing Educative Connectivity for Online Learning; more information about Plan Ceibal is available at <http://www.ceibal.org.uy>). *Plan Ceibal* is now targeting secondary education (youngsters from 12 to 18 years old) as well.

Although *Plan Ceibal* successfully enabled internet access to all its users, by claiming that all the child population of Uruguay is now connected it ignores the fact that access to technology transcends the mere physical immediacy. There are users with disabilities that difficult or prevent them from fully take advantage of the *Plan’s* potentials and opportunities. An ethnographic study conducted in the primary school *Dr. Ricardo Caritat*– the only public school in Uruguay for children with motor impairments – observed that a combination of factors, including the XO ergonomics, the software interaction design, the lack of suitable software accessibility helpers, and the limited availability of accessibility peripherals, undermine the XO’s accessibility. [4]

In spite of the fact that the *Plan Ceibal* program explicitly states that the children are the true owners of the computers, the accessibility problems discourage physically impaired children from appropriating this technology, and therefore, difficult their access to the knowledge society.

Accessing Ceibal

Thanks to OLPC laptops coming with an integrated webcam, a reasonably fast processor and a speaker, it is possible to develop multimodal interfaces to improve accessibility. [4] Potentially, multimodal interfaces accommodate a broader range of users than traditional graphical user interfaces (GUIs) or unimodal interfaces, allowing for the inclusion of users of different ages, skill levels, cognitive styles, sensory impairments, and other temporary or permanent disabilities. [5]

With the aim to address these problems, and to foster an authentic appropriation of this technology by children with motor impairments, an innovative interaction schema to access the XO was proposed. [4] The new schema avoids the “keyboard, mouse, screen” paradigm by allowing for the execution of actions that are triggered when the user shows an image to or occludes it from the XO’s camera, and by also providing multimodal sensory feedback.

This images can be of any kind (our implementation utilizes printed images created with a standard printer), as long as they meet certain requirements of resolution, contrast between foreground and background, and uniqueness to be easily identifiable and differentiable from one another. Images that can be considered for the interaction include pictographs (such as representations of animals, people, or means of transportation), ideograms (resembling concepts, actions, or instructions), words, letters, numbers, two-dimensional barcodes, among other symbols. In addition, the images can be of any size or

shape provided they fit in the field of view; can be printed in paper, cardboard, stickers, or other printing media; can vary in color; and can be glued or attached to different objects.

Since the images can be arranged in different supports, they can afford different user actions, like touching, rotating, or holding. This versatility gives designers and application developers the freedom to create different games or applications based on diverse interaction strategies.

From an educational point of view, this approach can potentially be employed in developing cognitive, affective, and psychomotor educational aspects.

Multimodal activities

Three different types of applications (in XO jargon, *activities*) were created to explore different educational strategies that could help develop children's motor and cognitive skills, improve their self-esteem, augment their autonomy and foster their relationship with the environment and with other persons.

The activities are as follows:

Activities focused on developing specific cognitive functions and skills involve presenting users with a problem and waiting for the right answer. The solution could demand sorting images (e.g., distributed on several printed cards with a rigid base), or picking, from a set of printed images, the one that contains the correct answer. For example, to develop children spatial relationships, the layout could consist of a set of images illustrating the relationships up-down, in-out, or open-closed. The user's goal is to identify the abstract relationships and matching them with the corresponding cards in the deck.

Activities focused on promoting digital inclusion and enhancing autonomy allow for the user to trigger predefined actions in the XO –e.g. opening an activity, unrolling a menu, controlling a game character, moving the mouse cursor, or selecting a tool– by choosing from a number of options printed on a proper media, such as a sheet of paper. Three activities are being developed: a *faux keyboard* that associates drawings to some keyboard keys (e.g. the arrow and enter keys), *the bookmark* where the user can navigate to pre-defined web sites by touching its corresponding drawing, and *the launcher*, a menu from where the user can run XO activities.

Activities focused on encouraging social, emotional and motivational aspects incorporate musical, recreational and narrative elements. One of the prototypes under development is an interactive storytelling application, which will be discussed in the next section.

The proposed activities share some common characteristics:

- Beyond the cognitive challenge associated to the process of triggering a specific action from the computer, all the activities demand children to reinforce their motor skills, either by seeking a printed card from a deck, pointing at (or occluding) an image, or raising an image to show it to the camera.
- The simplicity and versatility of the input device –e.g. with a piece of paper it is possible to create a keyboard– allow the teachers to create their own exercises, encouraging them to effectively use the XO as an educational tool for their classes.

- Regardless of the fact that the framework was designed for children with motor impairments, nothing prevents it from being used by children without those impairments.

By the massive use of these prototypes we expect to obtain data about their usability within this target population. Our observation indicates that the activities are perceived as highly attractive by its users, showing that it is possible to design new ones with a high motivational component.

Interactive Storytelling

Storytelling -or the art of telling stories- is a fundamental characteristic of mankind. In the words of Hamilton and Weiss, “storytelling is the oldest form of education”, since “people around the world have always told tales as a way of passing down their cultural beliefs, traditions, and history to future generations.” [6] The process of listening, creating, and telling stories is particularly important in the development of children: stories can help them to understand their world and to share it with others. [7] In early development stages, storytelling reinforces communication, recognition, and recall skills, favors social relationships between peers and adults, and provides meaning to their living experiences. In later stages, storytelling improve linguistic and literacy skills, and promote interpretation, analysis, and synthesis abilities. [8]

In addition, storytelling has been used as a method to work with children’s conflicts and concerns, helping them to “objectify and, at times, to personify the problems that they experience as oppressive.” [9] For children with disabilities, different storytelling approaches have been used to support the development of cognitive functions and skills. [8]

In recent years, interactive storytelling has become increasingly popular in the field of human-computer interaction. In 2010, the full-day workshop of the ACM’s (Association for Computing Machinery) Ninth International Conference on Interaction Design and Children (IDC 2010), titled “Interactive Storytelling for Children”, aimed to bring together researchers from different fields that share a common interest in the subject. [8]

Compared to traditional storytelling, interactive storytelling applications allow the audience to actively participate in the drama, by altering -during the course of the story- the action, character, dialogue, and narrative performance. As a consequence, interactive storytelling can multiply the narrative possibilities, upgrading the role of the audience from listeners to participants of the story. As in traditional storytelling, there exists the role of a storyteller, either human or synthetic, whose challenge is to make sure that the story maintains a certain level of quality.

This quality can be measured in terms of consistency, *enjoyability*, *memorability*, among other parameters. When designing and developing a digital interactive storyteller, these requirements can be difficult to accomplish since it is difficult to find a proper tradeoff between the story narrative and user interaction. [10]

Research in this field includes specific applications, such as the construction of furry storytelling robots to motivate children with developmental disabilities, augmented reality displays to communicate scien-

tific information in museums, and tangible interfaces for storytelling using physical objects (see, for example, [11]); studies about the educational value of authoring interactive storytelling in formal education, or how children can develop narrative skills by programming interactive storytelling games; and studies about using interactive storytelling for helping children with special needs. Garzotto, *et al*, provided a survey of papers related to interactive storytelling. [8]

ENABLING STORIES

Enabling Stories is a multimodal interaction-based interactive storytelling application, designed for children with motor or cognitive disabilities, as well as for children with normative development, that runs on OLPC's XO computers.

The application is not only an interactive storytelling game but also a tool for the stimulation of the development of specific cognitive functions and skills, as well as for the promotion of digital inclusion, and the improvement of social, emotional and motivational aspects on its users.

Enabling Stories performs the role of the storyteller. It is responsible for directing the story plot by modeling key aspects of the narrative, such as characters, places, possible interactions between characters, etc., and to present the story to the user.

Interacting with the storyteller –by setting scenes up or by answering to specific questions– the user is allowed to modify the story, building new ones on real time, and therefore actively participating in the drama. For example, the storyteller would describe a scene by using spoken text, images, music, video, etc. and then prompt the child for information.

The application supports an input modality based on the interaction schema mentioned before, as well as traditional input gestures, such as selecting a displayed option with the mouse. When an event requiring user interaction occurs, the storyteller waits for the user input. A rather trivial example would be: “the girl is taking a hike in the forest, who does she meet?”, the child, then would take one of the printed images (let's say, one with the drawing of a dog), and puts it in the space seen by the computer's camera. The storyteller then continues with the narration using the user input. Depending on the type of event, the storyteller could time out the scene and then continue with the following one.

Conclusions and future work

Uruguay's OLPC program, *Plan Ceibal*, aims to provide a connected computer to every child and teenager of the country. Different studies show that the provided computers are not accessible for children with motor or cognitive impairments. To foster the appropriation of these computers, we proposed different types of applications that explore different educational strategies, based on an interaction schema that avoids the traditional “keyboard, mouse, screen” paradigm.

One of these proposals, named *Enabling Stories*, is an interactive storytelling application supported by a multimodal interface. *Enabling Stories* is aimed to develop children's motor and mental skills, enhance their self-esteem, improve their autonomy, and favor social relationship between peers and adults.

Beyond the application characteristics that make it attractive, we speculate that children with motor impairments can benefit from the physical and cognitive challenge involved in the action of showing the printed images to the computer.

FUTURE WORK

A new stage of the work has commenced in June 2011, under the project “*NEXO: New Interaction Modalities for the XO*”. The project involves the study of the incidence of different types of applications, including *Enabling Stories*, in children development.

The study will be conducted by UDELAR graduate and undergraduate students of cognitive psychology and computer science, during a six-month period.

This stage includes the design and development of different types of applications, focused on developing cognitive functions and skills, enhancing children’s social domains, and improving emotional and motivational aspects.

Within this study we expect to evaluate if the proposed applications effectively represents a positive impact on different developmental domains (physical, cognitive, social, or emotional domains).

THE LEGACY OF EXPERIMENTS IN ART AND TECHNOLOGY (E.A.T.): AN ENVIRONMENTAL AESTHETICS

Christophe Leclercq

E.A.T.'s legacy rests on the early development of an environmental aesthetics. This aesthetics, however, does not focus on the idea of nature (as the prevalent notion of environment has it) but rather on the built and, particularly, the technological environment. This environmental aesthetics problematizes the nature/culture dichotomy in a manner that is of particular relevance to contexts that are increasingly infiltrated by technology.

Experiments in Art and Technology (E.A.T.) is a well-known example of interdisciplinarity at the intersection of art, science and technology. It was founded by Billy Klüver, Fred Waldhauer, Robert Whitman and Robert Rauschenberg in order to facilitate collaboration between artist, engineer and industry. As Branden W. Joseph wrote in *Artforum* in 2004: "Klüver bequeathed to us a set of questions and contradictions involving art, industry, technology, and corporate sponsorship that--amid the glitz of new technologies and the renewal of foreign wars--deserves a place at the forefront of our historical consciousness." [1] Indeed, E.A.T. sought to recognize the role of technology in society and especially the new responsibility of artists and engineers in complex industrial societies.

The organization has been examined in part by curators, art historians and researchers who focus mainly on the *9 Evenings: Theatre and Engineering festival* (1966) and, to a lesser degree, on the Pepsi-Cola Pavilion at "Expo '70", at the Osaka World Fair. The Pavilion can be seen, as Fred Waldhauer says, as "a culmination of the experiment during 9 Evenings." E.A.T. and its projects are often interpreted either in terms of their success, by defenders of new media art, or their failure, by contemporary art critics in the main.

From a different perspective, however, the Pavilion can be considered a turning point, and some experimental works and projects resulting from collaborations initiated by E.A.T. meaningful attempts to renew fundamental aesthetic questions. Closer examination of the statements associated with E.A.T. projects pre- or postdating the Pavilion, or even projects that remained unrealized (which are numerous and merit attention), reveals the omnipresence of the concept of "environment." Beyond the development of devices as tools or instruments, that would be available to other artists, this notion, investigated in *Oracle* and in the Pavilion, can be seen as a key concept in seeking to understand the switch by E.A.T. from an art to a non-art context. E.A.T.'s legacy can be said then to rest on the early development of an environmental aesthetics, which does not focus on the idea of nature (as the prevalent notion of "environment" has it [2]) but rather on the built and, particularly, the technological environment.

Following Allan Kaprow's *Assemblage, Environment and Happenings* or the exhibition *Environments, Situations, Spaces*, it is tempting to consider an environment as a new art form. The Oxford English Dictionary defines an environment in art as "a large structure designed to be experienced and enjoyed as a work of art with all (or most) of one's senses while surrounded by it, rather than from outside." The definition is precisely illustrated by a quote by Robert Whitman from *The New Yorker* on the Pepsi Pavilion.

[3] But the environment (“that which environs”) is a much more difficult notion, according to Frank Popper or Peter Sloterdijk. Contrary to the artistic concept of landscape – which implies the idea of a frame – the concept of environment seems to be used in art to question our understanding of our “surroundings”, and how it affects us and can be affected by us. As a result, certain of Tinguely, Rauschenberg and Cage's works can be seen as different attempts to focus on the perception of our shifting urban environment, in this case New York City.

Rauschenberg's *Oracle* is an essential work that deals primarily with this issue. Deeply affected by Jean Tinguely's self-destructive sculpture *Homage to New York* (1960), Rauschenberg subsequently tried to realize, with the help of Klüver, an “interactive environment where temperature, sound, smell, lights, etc., could be affected by the person who moved through it.” [4] This resulted in *Oracle*. First exhibited at Leo Castelli Gallery in 1965, this work consists of a console with an aluminium staircase housing AM radios and electronic control equipment, to which Rauschenberg added four other sculptural elements described by him as “gifts from the streets”: a round industrial duct in the form of a funnel; a window frame with duct; a car door mounted on a rolling typewriter table, with a large piece of crumpled metal behind it, and a basin combined with an air-conditioning duct through which water circulates. All of these assemblages were on wheels so that the artist could move them freely. As it is no longer possible to interact with the work, one has to revert to earlier descriptions of the experience, in the 1960s, to understand how this work problematises the perception of environment. Klüver specified that, in this installation at the Leo Castelli Gallery, “the viewer could freely walk among them and operate the controls on the staircase.” Visitors were able to move control the volume and the speed of the dial scan. “In full operation,” Klüver wrote, “*Oracle* becomes an animated cityscape.” As an active participant in the work, the visitor took part in this urban environment and was responsible for what he did. *Oracle* was also described by the art critic William Berkson as “a funhouse, a torture-chamber or a laboratory for testing perception.” This latter metaphor corresponds exactly to Andrew Forge's description:

To stand by the console is to be aware of a continual coming and going of sound, predominantly spatial. [...] The very sensation of hearing, it seems, has become a kind of looking. One doesn't know which way to point one's eyes, so strikingly does the sound reframe the appearance of the machines, giving them a kind of speed -despite the fact that they just stand there dinning- or if not speed, a kind of flashing nowhereness like parked cars seen peripherally from a speeding scooter. And as soon as you move away from the console, among the pieces, you find your movements, your familiar physical measuring of close distances becoming a matter of urgency to be set alongside this new space that you are hearing inside your head. [5]

Forge's description of his experience focused on the plasticity of sound and the mutual interdependence between seeing and hearing which Rauschenberg would explore further during the *9 Evenings* with his performance *Open Score*. This festival took place at the 66th Regiment Armory in New York, in 1966, as a result of several months of collaboration between artists and engineers from Bell Laboratories. According to Clarisse Bardiot, the Theater Electronic Environmental Module, known as the TEEM, was the “major achievement of *9 Evenings* and its most important message for the art experimentation that would follow.” [6] Designed to fulfil the function of an on-stage environmental electronic system, it enabled the performers to reconfigure the space in which the action took place by using a remote-control system for the lights, speakers, microphones, cameras, film, motors, etc. John Cage's statement for his performance *Variations VII* was to “use sounds available at the time of the performance” picked up indifferently inside or outside of the Armory. 10 telephone lines were installed in the Armory, open in different places in New York city including a restaurant, an electric power station, the New York Times

press room and Merce Cunningham's studio. In addition, there were contact microphones on the performing platform itself and on domestic appliances (a fan, a juicer, etc); there were also 20 radio bands, 2 television bands, and 2 Geiger counters. 30 photocells and lights set up around the performance area activated the different sound sources as the performers moved around. Classical musical composition and traditional instruments are here replaced by a protocol which welcomes, like *Oracle*, selected sounds "in the air" and challenges profoundly the perception of inner and outer exhibition space frontiers as well as the perception of distance.

McLuhan's theories – that John Cage always praised – were controversially discussed during the *9 Evenings*. The recognition of technology by Klüver and Rauschenberg as a "natural environment" resembled in a certain way the naturalization of technology as emphasized by the media theorist and essayist. The variable environments built in the Armory can also be interpreted as a means to employ "multiple models for exploration", McLuhan's so-called "method of our time", to make people aware of technology's effects on perception. Indeed, McLuhan described the role of the artist, with regard to the technological environment, as follows :

Environments are not passive wrappings, but are, rather, active processes which are invisible. The ground rules, pervasive structure, and over-all patterns of environments elude easy perception. Anti-environments, or counter-situations made by artists, provide means of direct attention and enable us to see and understand more clearly. [7]

Marcelyn Gow rightly established that Klüver's concept of the environment differs from McLuhan's understanding of a pervasive and ineluctable process. According to Gow, Klüver thought it "in relation to human interaction with technology or what could be called programming, in order to produce specific effects", i.e., where "feedback mechanisms" enable the effects of technology to be actively reshaped. [8] We can add that the core opposition, aesthetically, is based on the quantity *and* the quality of the feedback(s), that is to say between a conception of art as anti-environment (i.e as a reactive art form), and art as open-ended "experience, environment, process" (Barbara Rose), illustrated by the Pepsi-Cola Pavilion for Osaka '70.

The Pavilion was a unique opportunity to work with industrial support, in the manner expressed in the E.A.T manifesto. While not deeply involved in the project, Rauschenberg suggested that artists working on the project "shift their approach to include elements that appealed to all the senses rather than just the visual, that is, elements that would create what people would feel as an 'invisible' environment." [9] This "invisible environment" was quite different from McLuhan's determinist understanding of such an environment, since the visitors would be encouraged to participate and then to "create their own experience" in what they called a "living responsible environment." Despite the relationship with Pepsi breaking down, the design and development of artificial fog and of an indoor programmable environment, responding respectively to local weather conditions and to visitors, can be considered meaningful artistic research. Outside the pavilion, Fujiko Nakaya's designed a *Fog Sculpture* in collaboration with the physicist Thomas Mee. 2,250 special fog nozzles were developed to create an artificial fog made of pure water at the request of the artist. Pumps were programmed to respond to different weather conditions: an automatic control system for programming was designed with real-time feedback of local meteorological data; namely, wind direction, velocity, and wet/dry bulb temperatures transmitted from the sensors at 6-minute intervals. The artist described her work as a "negative sculpture" because atmospheric conditions sculpted the fog in a concrete sense. She thus abandoned so-called "artistic control" in the shaping of this hybrid nature-culture artefact. Here again, however, she defined a protocol. Inside the Pavilion, a hemispherical mirror made of aluminised Mylar produced striking optical effects. One of

these was an effect known in physics as 'real image', consisting of an upside down or inverted image that exists suspended in the 'real' space inside the dome, rather than in the 'virtual' image created by an ordinary mirror. (i.e. images produced in ordinary mirrors exist in a 'virtual' space behind the mirror itself). Above all, this interior space, consisting of the mirror plus lighting and sound systems, was also designed as an “instrument” to be used “by individuals from different professions who [would] come to the Pavilion to implement their program ideas, and through this participation be able to adjust, expand and extend their ideas in response to the situation and opportunities they [would] find there.” [10]

The Pavilion is a turning point not only because E.A.T. assumed an environmental approach to its activity but also because the team moved to a non-art context; in large part they weren't even sure what they were doing was art (they came to recognize it as such by the end of the project). The move to a non-art context – which had already been achieved by 1969 – may disturb the world of art but it makes sense from an environmental aesthetics approach. Thinking indeed that “the main influence of art and technology together will come in the area of the environment,” the aim of E.A.T. was redefined in 1969 by Klüver, to “encourage the artist-engineer collaboration to fulfil its potential as a revolutionary force in shaping the hardware and software of our technological environment.” [11] It is not a utopian definition since the nozzles developed for the Pavilion's Fog are currently used by Mee Industries Inc. in agriculture and industry, proving that successful transfer of an innovative technology, developed in collaboration with an artist, to industry is possible.

The word 'art', however, tended to be neglected in 'non-art' projects. Nevertheless, one can still recognize Klüver and Rauschenberg's aesthetic statements in an unfunded proposal for ten exhibitions. E.A.T. proposed a series of exhibitions for which the overall theme would be “Technology for the Individual: Recognition and Choices.” [12] Indeed, the subjects chosen represent “areas of technological change where the unresolved issues will affect the direction of technological development in advanced as well as developing societies.” The aim of these exhibitions was “to promote a recognition of the options presented by the new technology for the individual.” The exhibitions were planned for October 1969, with the opening of Automation House in New York City, established by Theodore Kheel for “people to adjust in a rapidly changing world of automation and helping the individual to have a sense of participation in the society in which she or he lives.” These exhibitions would have been designed by contemporary artists in collaboration with experts in the appropriate fields. The working titles for the ten exhibitions speak for themselves: “Variations of the Body: Genetics” by Allen Ginsberg; “Variations of the Body: Renovation, Transformation and Extension” by Steve Paxton; “Interactive Technology for the Three-year-old: Environments Designed by Teenagers” by Olga Klüver and Robert Rauschenberg; “Woman: Her Technological Environment” by Jean Dupuy; “Sports Equipment: Individual and Nature” by Claes Oldenburg; “Secrecy, Privacy and Snaring: Effect of the new communication and information technology” by William Burroughs; “Automation: Involvement or Alienation?” by Jean Tinguely; “Technology and the Environment: an Interactive, Computer-Simulated Ecosystem” by John Cage; “Atomic Energy: the Cloud and the Clear Sky” by Öyvind Fahlstrom; and “Shaping the Environment: Participation by the Individual” by Robert Whitman. This list comprehensively reveals the different preoccupations of the artists by this time, the extent to which they were concerned by the shifting environment they lived in and their desire to analyse the mix of technology, human and nature subsumed within this concept. Rauschenberg and Whitman's propositions in particular suggest an insistence on personal involvement as opposed to a more analytic approach.

Projects Outside Art (1969-1972) notably illustrated how E.A.T. paid attention to the specificity of a given environment, in contrast to McLuhan's position. Presented as “an exhibition of realizable projects in the environment”, interdisciplinary teams were asked to propose a project dealing with education,

health, housing, concern for the natural environment, climate control, transportation, energy, etc., using the most innovative technology. Participants were asked “to recognize, in particular, the scale adequate for the problem undertaken, social and ecological effects, organizational methods necessary for realizing the projects” and for their project to “apply to specific geographical environments.” In *Children and Communication*, two groups of children from remote parts of the city of New York (considered as a rich and a poor district) were placed in two connected environments built by Robert Whitman. They were invited to experiment with available communication technology through the use of telex, fax, etc., a situation that Hans Ulrich Obrist compared to “a sketch for connected schools ages before the emergence of the Internet.” Another selected project, *City Agriculture*, aimed at creating closed-environment systems that would make it feasible to undertake city agriculture on a large scale. This also sounds extremely contemporary. Crossing different cultures or sociological contexts – city/countryside, rich/poor – was considered as a means of discovering solutions to contemporary problems while developing creativity.

Part of the multi-dimensional scaling projects or studies realized in collaboration with psychologists at Bell Laboratories, A Scaling Project Facing the Nation precisely dealt with the perception of social problems. The project aimed to correlate 22 economic, technological and social problems (i.e. unemployment, inadequate healthcare, pollution of the environment, racism, over-population, war, misuses of technology, etc.) with technical and scientific resources applicable to these areas. Individuals were given questionnaires and were asked to evaluate the relation between these problems and different contexts. The data was then processed by statistical analysis algorithms – the INDSCAL program developed by Douglas Carroll and Myron Wish at Bell Telephone Laboratories – and “the results were such that the axes in a three-dimensional space could be interpreted as local political--national political; technological--non technological; and moral individual--large scale organizational.” The subjects and the techniques involved (information visualization) are at the forefront of our contemporary preoccupations.

This move “outside art” makes sense as an attempt to escape the reification of art by the cultural industries and by the art world itself and to promote, as Klüver has it, variety and choice against repetition and uniformity. Nevertheless this move was misleadingly interpreted as a departure from aesthetics. However, the importance of aesthetic decisions and aesthetic conflicts in collaborative situations had already been noted and an aesthetics symposium was scheduled as part of the Projects Outside Art in 1970 to analyse these problems as well as to question the relevance of interaction between artists and engineers and of artists participating in non-art projects.

Through the concept of environment, the works and projects described stress the notion of artist or engineer control in art, technology and sophisticated industrial societies, and subsequently the role the artist can play therein. There was a belief in the possibility of improving the world quite different from postmodern cynicism. This belief placed the emphasis on the artists themselves – and in a larger context, on individual responsibility in a high-industrial context. E.A.T.'s environmental aesthetics does not consist of an aesthetic appreciation of natural, human environments or indistinct everyday activities. Rather, it is a question of examining art through the concept of environment and the environment through the practice of art; recognising a specific artistic expertise for environmental issues in art or non-art projects which require collaboration between artist and engineer. Moreover, this aesthetics problematises the nature/culture dichotomy in a manner that is of particular relevance to contemporary contexts increasingly infiltrated by technology. As a result, it can be brought to bear, fruitfully, on discussions of contemporary strategies in art and design, ecology and technology.

PHYSICAL CINEMA: PRACTITIONERS AND RECENT PRACTICE

MICHAEL LEGGETT

Physical theatre, Live Art and Cinema have through performer and filmmaker established a vigorous practice in recent years, challenging the confines of more traditional art forms. Practitioners have come together with audiences to create between them a physical cinema converging as a series of spatial modes. This paper will outline some recent developments in this interdisciplinary field.

Fig. 2. Brunel, 1983, Mike Leggett (filmmaker), John Downie (playwright) 16mm film and performance installation © Leggett & Downie

Fig. 3. Critical Path Lightways, 2010, Alan Schacher (Live Artist), Mike Leggett (filmmaker), video and lighting installation © Leggett & Schacher.

Physical theatre, Live Art and Cinema have through the processes of collaboration between performer and filmmaker, established a vigorous practice in recent years that challenges the confines of established art forms. Practitioners have come together with audiences to create between them, a physical cinema converging as a series of spatial modes. Place as much as practice determines the kind of experience a visitor, or participant, will encounter. Practitioners employ the phenomena of light and sound, darkness and silence, to propose courses of actions and ranges of responses for the individual participant to follow, or be provoked by. The participant becomes a performer, bringing the work into being through the realisation of a physical cinema. In performing the work, the participant echoes the practitioners own physical performance explored during the making of the moving image artwork.

Experiencing the phenomena of motion pictures in the past became associated with place – the building called the cinema – as certain conditions were required to enable the images to be seen and later, for them to be accompanied by sound. Technology expanded the requirements of place from darkened spaces in which light was reflected from a screen, to the semi-darkened space of the living room, with light emitting from the screen. Home movies spread the making of motion pictures, on film and video-tape, to a section of the cinema audience confident with manipulating tools; this included an ever increasing number of artists.

At the London Filmmakers Co-op in the 1970s, we became mechanics and chemists and set up printing and processing machines, adjacent to the cinema space and a distribution office; integrated practice was

how we described what is now called interdisciplinary arts practice. Using the printer for instance, I was able to duplicate a fragment of 16mm time-lapse film many times over by simply looping the original film footage in the machine (Fig.1). A body of work emerged exploring these kinematic principles, the fundamentals of cinema, focussed on material presence and structuring processes. The experience for the viewing participant as part of the process was, and remains, attentive, self-reflexive and closely perceptual. [1]

Part of this practice expanded away from the convention of a projection box facing a screen with the seated audience in between, toward open gallery-type spaces, where the audience moved between projectors and screens. Performance, in effect, occurred in front of both the camera and the screen.

Eve Kalyva's consideration of what constitutes a performance is useful in this context. She has noted:

"Surely there is the factor of threat and keeping it under check, for presumably ... one can interfere with a performance; or to put it another way, the whole point of a performance is this conditional interaction." [2]

Conditional interaction refers to the physical space between the audience and the performance. The invisible fourth wall in theatre or cinema is the membrane through which the product(ion) is delivered, regardless of the state, or frame of mind, of the audience. The agency of each member of an audience in conventional proscenium arch venues is restricted by custom, to removing oneself from the auditorium.

Such was the case in the Unword series of performances which commenced as a collaboration between myself, a filmmaker, and a visual artist; whilst a framing distance would be maintained by the physical delineation of the space, the rules for the audience kept them on the other side of the invisible membrane as spectators (of a spectacle) and not participants. The film (and later digital documentation), [3] as artworks in their own right, similarly maintain the distancing frame of the screen as a visible membrane. The conditions for response, reflexive rather than interactive, are reversed; with the liveness and the presence of the performer(s) removed, the condition of interaction changes the terms of individual agency. The screened image can now be approached and appropriated into the physical space of the viewer. [4] The modality of encounter switches from one tradition to another; from that of theatre and cinema, where agency is limited, to that of the gallery, where agency in the physical act of viewing is essential. As Kalyva has observed; "This act exposes the limits of social constructs such as subject and object, galleries and spectators, not at the level of the *effect*, but of the mechanisms that create, enable, and sustain such constructs." [5]

What is quickly understood is the relationship between the spatiality of the act of viewing – audience to performer(s), screen to viewer – and the hybrid spatiality of the images and sounds they observe.

Paul Dourish describes this as a "...social act of communication as participation and selection..",[6] and the performative occurs through both the advance of motion picture technologies – in this case, digital video and the video projector – and the willingness of the artists to experiment with the possibilities thereby afforded.

In tracking the morphology of the moving image in this way – from live performance to its record, a palpable presence when film is projected as performance, to many variations of encounter when video is projected – a physical cinema is located not in places but in attitudes and ideas.

My own practice included collaboration with playwrights, dancers, scientists, musicians, technicians, programmers and comedians in pursuit of expanding the boundaries of practice. *A History of Airports* [7] brought together all of these skills into a converted warehouse space through which the audience moved, encountering performers and screens during the 90–minutes of the show. Promenade theatre as it was known in Britain in the 1980s, brought together geographically local communities with professional artists. The restrictive and contained practice of theatre was replaced by a state of conditional interaction, that enabled spatial participation within the performance area whilst witnessing the work of the production through words, screens and physical presence.

In another similar collaboration, the convention of an audience facing a stage, like the audience facing a proscenium arch screen in the local cinema, was maintained. The mechanics of film back projection was visible as a part of the action in the performance area concerned with the career of the British 19th Century engineer Brunel. The roll of film containing moving images of carriage through the countryside, was loaded on the first of a row of projectors and then through a series of supports threaded through each of the six projectors on the gantry (Fig. 2). This was an analogue solution to a synchronised multi–screen array and thus required constant adjustment by a small team of minders over the film's ten–minute duration.

In the 2010 Biennale of Sydney, Isaac Julien showed the multi–screen work *Ten Thousand Waves*. [8] The 50–minute cycle of the work references the Chinese film industry, the rural peasantry, the diaspora and as a part of the narrative, emergency services footage documents the atrocious drowning of twenty–three Chinese migrant workers on the mudflats of Morecambe Bay in the UK during 2004. Visitors to the exhibit were able to promenade the 20 x 40 meter space, choosing where to stand or sit and in which direction to place their gaze. The sudden duplication of an image behind another encouraged the viewer to redirect their gaze to another alignment of screens, either by a turn of the head or a shift of position in the space. Interaction is conditional on engaging with the internationalist themes of the narrative, tightly controlled in the structuring of the work and, like Hollywood's product, imported into a suitably equipped venue. Using a hard disc array delivering perfectly synchronised sound and image across nine screens, the cinema system ran all day, every day for the three months of the Biennale; switching on at the beginning of the day, switching off at the end.

Physical cinema as promenade theatre is developed in my recent work with Alan Schacher at Critical Path, the choreographic research centre in Sydney. The interdisciplinary collaboration between a filmmaker and a Live Art artist and performer, a sound composer, other performers and an audience investigated 'the multiplication of space and presence to generate looped choreography–image systems'. (Fig. 3) The location itself, a heritage building, is the place and substance of audience experience, augmented by projected and performed interventions into the buildings fabric and its human context.

In all of these collaborative interdisciplinary works there are moments where for the viewer, the moving image is tenuous and seemingly fragile. There is a breaking down in the moving image's connection with a visual world which we can comfortably recognise. Jesse Shapins affirms in a recent book; "The shift enabled by new media, in particular the internet, mobile devices and wireless technologies, is the ability to literally transform the lived experience of the city into an active read/write databasetoday, the media artist can craft physical cinema that takes place on the streets of the city." [9] 'Taking place' means the act of participation, whether initiator or participant. For instance, the miniature works for mobile device made by the Sydney artist, Sam James are short poetic statements that like a book, can be opened at any moment in any place, to augment the passage of time. [10]

When the context is provided, as in Isaac Julien's work, the narrative of oppressed people plays out before us. Throughout 2011 we have become familiar with receiving moving images from the streets of the Arab world; moving in the sense that they were shot on mobile phones, but emphatically moving in the sense that we were encouraged to believe we were witnessing the transitioning of a group of nations into another stage of social and political development.

The use of mobile tools to both *organise* gatherings by mostly young people, and to *record* the events as they unfold have attracted much comment. The moving image recordings made and relayed to the world we experience only as observers of the media accounts, editorialised to encourage natural feelings of empathy and even admiration for their acts of defiance.

This is a physical cinematic practice based on the physicality of place and the dynamics of context, the tumble of events far from the planned situations encountered in the art gallery, festival and cinemathèque.

To haul these images into another but related context, the performers and activities develop as a series of durational and movement elements, approaching Deleuze's discussions of Cinema and the terms movement-image and time-image. The first term is the series of actions which relay the intent of the narrative – gatherings of people in public places to express the opposition of the governed to the governors. The second term can be applied to the fragments of moving image recording the events with mobile phone; the brevity of the images, the indistinct appearance and the media who convey them locally and to the world repeatedly for each and every News update, even several times in each bulletin. Though these time-images are different from the kind Deleuze described as existing in art house cinema. For the protagonists, the *indexical* moment of confrontation is relived each time they are seen again in the present. For the watching world the images are *icons* to a state of revolt. These moving images grabbed and relayed by mobile phone move rapidly between function and use; as Deleuze suggested, "A flickering brain, which re-links or creates loops – this is cinema." [11]

As expressions of faith in place and culture, these revolutionaries are the flux of change, an expression of a culture. This kind of mobility as an example of a physical cinema is the converse of the meanings fixed through representation in pictures and carvings say in Medieval and Renaissance churches, through which the audience move. The 'conditional interaction' requires that we remain quiet and contemplative as we move between the icons, in the same way as we regard the icons of celebrities performing on the screen in popular cinema today.

Conclusion

Developments in the interdisciplinary fields of art, science and technology have sought aesthetic change over the previous forty years, not only the last decade. From mobile screens and projectors that emphasise the cerebral experience of narrative encountered in the external settings of urban public spaces; to temporary projection surfaces and rigged light devices providing audience experience of the interior / exterior of place, activated through mobility within and around a specific locality. As a form of promenade theatre, new technologies have extended qualities and the range of audience experiences through touch screen and sensing systems. Accessing motion picture collections and augmenting performance as an extended practice, form the core of these experimental investigations.

DEVIANT MEDIA TACTICS: CREATING FACES

Asko Lehmuskallio

Increasingly, forms of deviant acts have emerged: images are reworked, fake-identities employed and existing mediated communication is organized into novel forms. By focusing on Goffman's notion of 'face' as a situational image of self, constructed according socially approved moral attributes, this paper explores deviant media tactics as sets of images promoting other kinds of moral attributes, and thus other forms of maintaining face.

With increasing digital mediation of everyday communication, novel forms of deviant acts have emerged: political posters of candidates are reworked, fake-identities employed and existing mediated communication is organized into novel forms. Empirical examples of deviant media tactics abound. Take for example the reworked posters of parliamentary candidates during the election in 2011 in Finland. The acting prime minister at that time, Mari Kiviniemi, lent her face to her political party's campaign, accompanied by slogans such as "This country has to be led responsibly, with agreements, not by ripping it apart" and "Do you want to change Finland? So do I".

The 800 000 euro campaign was seen on television, the Internet, newspapers and outdoors, and was designed by the advertising agency Skandaali, a part of the Publicis Group Worldwide advertising and communications company.

With the help of digital software, animal rights activists targeted Kiviniemi's campaign in order raise attention to fur trade in Finland, and Kiviniemi's reluctance as prime minister to address animal welfare issues associated with it. Special attention in mass media was guaranteed when reworking some of Kiviniemi's outdoor advertisements, printing the reworks in billboard format and plastering them on top of the original advertisements. The advertisements were slightly modified, resembling the original ads, with slogans such as "Do you want animals in small cages? So do I" and "A fox without stimuli? Great."

Kiviniemi's mouth received red color connoting blood, but in a way that did not make it instantly evident if these were original advertisements or reworked.

These techniques of deviance, and the normative ascriptions associated with them, suggest a different morality than presented in the original advertisements. They bring to light issues that are kept invisible in the original communication acts, trying to engage interactive communication, instead of quasi-mediated communication.

Similar techniques are used for a wide variety of purposes, and techniques of deviance and specific normative ascriptions do not always go hand in hand. In making moral dimensions of visual communication acts explicit, as well as the mediating effects of the techniques used, we can come closer to working on situationally shared understandings of the kinds of communication environments we'd prefer.

Advertising as trapping

Advertising, as we all know, strives "to transform the way people think, feel and ultimately behave" as one of Publicis advertising networks, the Leo Burnett Group puts it on their website.

Following the idea of advertisements' transformative effects, advertising images, created in order to influence bodies' behavior, can be understood as traps, because they are constructed in order to impede the passage of unsuspecting bodies and hold them in suspension, eliciting particular response. Alfred Gell [1] has drawn this analogy to trapping for artworks with complex intentionalities, I suggest that the metaphor of trapping suits also advertisements.

Marketing language itself is filled with concepts from the world of hunting and trapping. 'The hunt for customers', 'cool hunting' and 'customer trapping' are examples for the use of this kind of language. In saturated urban environments, images are used in winning customers, by claiming that, as the German marketing authority Werner Kroeber-Riel famously suggests, "Images are quick shots in the brain" ("Bilder sind schnelle Schüsse ins Gehirn"[2]). The assumption behind this idea is that images are processed by beholders subconsciously and emotionally, and that images are remembered much longer than for example text. There are various counterexamples for this general assumption about images, but of importance is a widely employed reasoning why images are used in advertising in order to influence customer decisions.

In designing advertisements, advertisers inscribe intentionality into the artifacts created in order to guide the behavior of those seeing them. The created traps are both models of their creators, as well as models of their victims, of those to be trapped. Functional traps are not all purpose devices, but they have to fit the behavior of those to be trapped, their techniques of the body. A significant amount of marketing research, for example, is done in order to learn how customers use the kinds of products advertised, in order to attune both products and advertisements to customers' behavior. When behavioral action is known, it can be modified with the help of successful advertisements.

Advertising traps are not lethal, nor do those trapped necessarily experience being caught by a functioning trap as negative, but often enjoy finding for example novel products, using them with ease and buying them for themselves and as gifts to others. In political advertising before parliamentary elections, an obvious purpose of advertising traps is to get people voting those advertised for. Political advertising, done in order to influence and possibly change citizens' behavior, is a means to change previous voting behavior in favor of new candidates.

Advertisements are interesting examples for discussing deviant behavior, because many advertisements per se constitute a norm for public communication, a communicative form accepted as part of our everyday experience. But the intentions behind advertising are geared usually towards *transformative* effects, towards *deviating* from earlier behavior. Of the two examples presented, the 800 000 euro campaign is seen by many as a form of 'standard' and 'normal' communicative behavior, because explicitly in that way influential societal actors communicate publicly. Only the rework is considered deviant, because it deviates from this widely accepted communicative norm.

This shows the relationality of deviant behavior, since actions can only deviate from something that is not regarded to be deviant, such as 'normal', 'accepted' and 'standard' behavior.

Embodied everyday communication

The digital mediation of everyday communication lures us sometimes to think that these kind of acts break with former communicative practices. In a way they do, since the communicative means we have

today at hand differ from the ones used earlier, but too often the discourse on the effects of digital mediation forgets the elementary interconnection between bodies and media. Our techniques for communication are first and foremost techniques of the body, [3] although they take in a 'digital era' artifactual form. Hans Belting [4] suggests that we use our bodies as media in communication, and it is in his sense that Erving Goffman can be understood as a media theorist with a fine-grained understanding of the ways in which we use our bodies as media in interaction. The medium Goffman has paid most attention to in his approach to studying communication is the human body.

Goffman has studied presentations of self with the help of theater metaphors, focusing especially on how bodies present self in different situations and why they do so. Instead of being interested in the informative dimension of communication, he focuses explicitly on the ritual side of interaction, on the ways in which communities and communality is created within interaction. Goffman uses face as his main concept around which he explains the communicative rituals in reciprocal interaction. Importantly, face is for Goffman "an image of self delineated in terms of approved social attributes." [5] With face-work, the work needed to create situationally proper face, we create images of situationally positive social values, such as honesty, trustworthiness and friendliness. With the help of face, created as an image on one's body serving as medium, we seek to orient interaction to a specific direction. By performing according to accepted social attributes and re-presenting them in mutual interaction we create actively moral sociality. Proper face serves as an index for mutual solidarity.

In face-work, we perform moral characters that are emotionally rewarded or sanctioned. Performing proper face is valued and acknowledged by interactional partners and is emotionally satisfying, whereas unsuccessful face-work accounts for blushing, shame, embarrassment and other unpleasant feelings. What is especially interesting here is that in face-to-face interaction mutual face-work has agency in stabilizing social interaction.

The original political advertisements shown suggest a specific face 'delineated in terms of approved social attributes' which voting citizens' would choose as their candidate when voting on election day in the voting booth. If the advertisement is successful, and transforms 'the way people think, feel and ultimately behave' it maintains social order, hierarchies and thus power structures and does not deviate from a situationally shared sociality. The acting prime minister will continue as prime minister after the elections, and the communicative methods chosen have worked in 'trapping' as intended.

Goffman's theory of face rests on Durkheim's understanding of the sacred. According to Durkheim the social reality of communities is constructed substantially around sacred things, which are special and treated with prohibitions. Durkheim believed that communities stay together by fostering the special and prohibited sacred with the help of rites and beliefs. The sacred is for Durkheim a universal phenomenon: without a common sacred communal life does not exist. [6]

Maintaining face is in Goffman's understanding sacred, which we guarantee with the help of a wide array of interaction rituals. Interaction rituals uphold common morale, and thus shared ways of situationally presenting face. Face is a sacred part of interaction that creates a temporary bond between those who interact, with elaborate interaction rituals advising how to deal with things treated as sacred. From a social perspective, this kind of a "ritual is a mechanism of mutually focused emotion and attention producing a momentarily shared reality, which thereby generates solidarity and symbols of group membership." [7] These symbols of group membership might be preserved in visual form on media that extend the ephemerality of face-to-face interaction.

By challenging particular ways of presenting face we challenge the moral foundation of interaction rituals. When we look at someone for too long, or when we do not look at her at all, we violate situational interaction rituals, situational visual orders. The face, as a sacred part of interaction, is both used in order to create 'successful' interaction rituals, but as well in desecrating communicative partners. The reworking of Kiviniemi's face in political advertisements by adding red paint to her mouth suggesting blood, and using slogans in her name that create other associations than the political advertisement as a trap for voters initially intended, suggests other kinds of moral attributes, and thus other forms of maintaining face.

Surveillant subversion

The kinds of tactics presented by those in communicatively weak positions are often applauded by critical audiences who want to question existing social and visual orders, and especially so if questioning the moral foundations of contemporary socioeconomic structures. Although highly creative, interesting and to some extent efficient (and at times illegal), these kinds of communicative techniques are not preserved to critical minorities, but employed as well by actors with a heavy supporting apparatus, often for very different kinds of purposes than employed in small-scale activism.

A telling example comes from Simon Menner's work at the Stasi archives opened for research, in which he found visual strategies employed in intelligence and surveillance work. [8] The Ministry for State Security (Ministerium für Staatssicherheit), also known as Stasi, was the intelligence service of the German Democratic Republic (DDR). Their aim was to ensure that deviant acts in the population were not made, and if they were, that deviance could be uprooted, if necessary.

Menner discovered two practices of special interest for our discussion: the first was the use of Polaroid photographs for taking pictures of homes to be searched just before the actual search done, so that all items could be placed in correct order again. The intention of this practice was that the people whose homes were searched never noticed any searches done. The second example is a photo set of spies presenting various outfits in order to 'fit in' into everyday social situations, so that they are not identified as spies. Here the deviant acts, morally questioned by those not participating in them, were masked as being part of situationally shared visual orders that seemed socially approvable. Any discreditations were done later on, after first suggesting a shared social reality with 'mutually focused emotion and attention producing a momentarily shared reality'.

Goffman focuses in his discussion of interaction rituals explicitly on expressions given off, which are non-verbal ways of influencing social interaction, as done in the case of Stasi spies dressing in order not to deviate and raise suspicion in the eyes of others. He attests communication partners a high skill in reading expressions given off, understanding that specific kinds of gestures, attires and verbal expressions are specifically crafted for particular situations. But in situational interaction, talking to Stasi agents dressed up as tourists for example, we have to "accept the individual on faith, offering him a just return while he is present [...] in exchange for something whose true value will not be established after he has left [... our] presence." [9] Deviance is thus not always recognized as such before it is possibly too late.

Unintended subversion

The examples discussed are examples of intended actions deviating from everyday action precisely in order to trap and transform those interacted with. Instead of sharing situational morality, the interaction partner's face is questioned either during the communication act itself, or later on when evidence of deviant behavior has been found. If the trap set up triggers, morally despised behavior is made known and is, perhaps, sanctioned or transformed.

In our contemporary here and now, marked by global flows and translocally shared practices, a wide array of deviances do not result from trapping, intending to transform the behavior of others, but due to cherishing situational practices shared with people dear to oneself. Public praying, hand-holding or kissing is in some places seen to deviate from morally expected behavior and thus contests situationally shared interactions. When done by migrants, tourists, 'parasocial' beings on television or in movies the deviances are often unintended. Too often in these cases special techniques are policed (e.g. specific techniques of praying, hand-holding or kissing), instead of discussing the actual moral implications behind these acts. In quite a few cases, if actually taking up the moral foundations of specific actions, the techniques employed would not be that problematic after all.

The role of mediation

Although Goffman's approach is especially valuable and useful for studying deviant acts, focusing solely on symbolic action does not give us any information about the role of the specific medium used to create and regard normative or deviant images. The role of devices used is here secondary, since from this perspective on images the role of the medium used is, surprisingly enough, not essential for discussing interaction rituals. In Goffman's theory social interaction is ordered around the face, an image of the self, which is regarded as a nearly anthropological universal. Thus various versions of presentations of self can be found in different contexts, face-to-face, on profile pictures of social network sites or ways of decorating one's home.

The transforming effects of mediation are best understood in relation to embodied actions, and in relation to the inherent processuality of situational interaction. Our bodies are our first medium used when interacting with others, used in order to show social cues of accepted or deviant behavior. The mediation of everyday communication, while sitting at computer screens and navigating via various software applications from e-mail programs, social network sites to blogs and news sources translates the kinds of cues that can be used in social interaction. Our social encounters in these kinds of digital environments are often shorter, more condensed and interaction partners have, if they choose so, usually more time to prepare their communicative acts compared to the time available in face-to-face behavior. This opens up various spaces for communicative acts that can transgress expected processes of social interaction. Activists have famously made it to television interviews and spurred heated debate with fake identities just by creating a web site and an e-mail address suggesting to represent an institution or person in whose name they communicate. When contacted, their mails have seemed professional enough in order to convince their interactional counterparts of their performed identity. [10] These acts of deviance done in order to discredit other kinds of actions considered immoral have been possible explicitly because of changes in the mediation of communication. Less cues given off, prepared well enough in advance, have made it difficult to not to 'accept the individual on faith, offering him a just return while he is present [...] in exchange for something whose true value will not be established after he has left [...] our] presence.' Often when it is too late.

Technology employed can itself lead to deviant acts, as has happened to quite a few who have either not understood the mediations they use in communicating in the first place, or the changes employed later to these systems. Social network sites that are constructed in ways that do not let users control their communicative acts as they have been used to have led to deviant acts that would have been considered normal among the intended communication partners. Because of this, employees have been fired, social relationships have been broken, and some know a little more about their relatives than they'd possibly like to. [11]

When differentiating between techniques employed and the normative ascriptions associated with them it becomes clear that they are often not similar 'things'. In our everyday interaction they are nevertheless tightly integrated: it matters how we maintain face.

POP ENTRAINMENT

Jon Leidecker

As the techniques of Audio Collage slowly migrated from formal conceptual practice to the commercial mainstream, a mood of cautious experimentation gave way to cavalier misrepresentation. But even the most problematic examples of music that caricatures the cultures from which it borrows still inevitably raise useful challenges to ownership, and the paradigms of authorship and individual intent.

Entrance

By the early 1960's, the location of what the listening audience perceived to be a musical composition was in the process of migrating, moving from the classical domain of written notation on paper to the carefully engineered audio recording. Tape collages, new compositions created from pre-existing recordings of earlier ones, made this process overt and audible to the listener. A commonly reoccurring concern in many of these early pieces was the juxtaposition of the music of different cultures, an attempt to compose the music of what Marshall McLuhan referred to as the Global Village. The idealized definition of music as a universal language could now be examined and challenged with formal explorations, both in Utopian pieces attempting to synthesize new harmonies between disparate musical disciplines, such as in Stockhausen's "Hymnen", Teiji Ito's "Tenno" or Ruth Anderson's "DUMP", and in critical investigations that juxtaposed seemingly similar sounds to underline the wildly different meanings when those sounds were heard in their original contexts, such as Richard Maxfield's "Bacchanale" and James Tenney's "Viet-Flakes". Some of these new harmonies were beautiful, some were violent, and which of these were which depended on the perspective of the listener. But the works of this early period were not easily mistaken for mere entertainment – the pleasures they evoked were often the exact result of the questions they were formally asking about this new village, and what it even meant that this music could now exist. As the influence and the practice of these art music collagists were taken up by others, first by experimental pop musicians, and later by commercial Hip Hop artists, some of those questions were drowned out by other concerns. Questions of authorship, collaboration and exactly what agencies are being expressed in a tradition that were naturally raised by the earliest tape collages often seem to go missing when music settles into the guise of simple entertainment. But we find that those questions are never lost entirely, as they lie too close to the intrinsic nature of the practice itself.

Experiment

"Sometimes it seems to be better when the musician cannot hear the other one during his recording", said Holger Czukay about his classic track "Persian Love". A student of Stockhausen's and a founder of the legendary experimental German rock group Can, the track is the centerpiece of his 1979 debut solo album "Movies", and is one of the first pop songs whose lead vocals are sourced entirely from a sampled recording. Built around a shortwave recording taped off from Radio Tehran by the composer which has

been painstakingly synchronized to new music written and performed by Czukay, the cascading rhythms of the original Iranian vocalists have gone missing beneath a swaying 2/4 beat. But their melodies still seem to fit perfectly over the slowly modulating chords, creating a truly striking hybrid. After the seamless first impression, the piece reveals itself as having required hours of meticulous listening and editing in order to exist. The hybrid is also one that could have only been realized through appropriation; the vocalists' mastery of their own idiom would have almost certainly made it impossible to sing the same lines in accompaniment to the shifting key changes suggested by Czukay's new chords. In much the same way that sheet music allowed composers to fashion and perform harmonies more complicated than performers could improvise, recordings allow for cross-cultural fusions to become audible. And once made audible, the most promising and relevant of these hybrids can be intuitively learned and evolved by musicians in live practice.

David Byrne & Brian Eno's 1981 album "My Life In The Bush Of Ghosts" expanded the concept of Czukay's track to an entire album of songs whose lead vocals were sampled from talk radio samples and globally sourced field recordings of spiritual and religious ceremonies. The track "Qu'ran", which sampled Algerian Muslims chanting the Koran, drew the attention of the World Council of Islam in the UK, who sent Byrne & Eno's label a letter the year after the record's release to signal that a recitation of their holy book to funk music constituted a religious offense. Byrne & Eno responded by agreeing to remove the track from future European and eventually all editions of the record. For all of the positive connotations that the word 'Hybridity' has for artists, in Post-Colonial Studies the word is precisely used to describe the "new transcultural forms [created] within the contact zone produced by colonization". Or as Byrne later noted, musical fusions often result not from collaborative choice but as the result of "unfortunate circumstances, like slavery or something else." Though some have decried what they see as a pointless act of self-censorship in an age where the track can easily be found online, the choice to quietly withhold the track without a mention of its existence on the 2006 global reissue of the album provides an interesting example of an attempt to show respect to the sampled culture, long after the initial act of creation.

These two albums stand at the mid-point between their early 60's art music collage predecessors, and the appropriations of Persian, Egyptian and Indian music that would explode into the language of Hip Hop in the late 90's.

Entertainment

A host of lawsuits in the late 80's and early 90's brought the Golden Age of Hip Hop to an end, the musical development of which had been defined by an increased density and wider range of juxtaposed sample sources, as typified by bands like De La Soul and Public Enemy. Increasingly forced into accountability in the wake of these lawsuits, record labels began the meticulous work of clearing the samples uti-

lized by their artists. Firms specializing in securing these rights began to flourish, offering specialized relationships within the music industry that helped them broker the best deals between labels. By the mid to late 90's, the artists working within the intrinsically referential genre of Hip Hop were generating such revenue that it always seemed to be better to be safe than sorry when it came time to license nearly any sound or concept utilized or even remotely referenced in their songs.

So it is all the more interesting to observe the utterly cavalier attitude these same labels adopted when their artists began to sample outside of the known products of the Western record industry. Jay-Z's 1999 track "Big Pimpin'", produced by Timbaland, is built around a four bar loop of the 1957 song "Khosara", composed by Baligh Hamdy and made internationally famous by Abdel Halim Hafez, one of Egypt's most beloved and popular performers. The loop was initially thought to have been rerecorded with modern production values by Timbaland, but was later found to have been directly lifted from a cover version found on Hossam Ramzy's 1995 CD "The Best of Bellydance from Egypt, Lebanon, Turkey". On an album whose liner notes are filled with publishing credits for the samples used on nearly every track, the lack of publishing information for "Big Pimpin'" was striking, especially considering its debt to a song that was instantly recognizable to an audience of millions outside of the United States. Similarly, the publishing for the 2002 track "Addictive", produced by DJ Quik for the artist Truth Hurts, failed to disclose Bappi Lahiri as the composer of the song "Thoda Resham Lagta Hai", which provided the 16 bar foundation on which all the additional melodies are based. And audible in nearly every second of the song is the unmistakable voice of the great Bollywood singer Lata Mangeshkar, creating a presence so strong that even listeners unfamiliar with the original song heard the production as a particularly daring act of musical borrowing.

Artists have traditionally enjoyed a tiny bit more latitude than journalists when it comes to issues of plagiarism; giving a personal voice to material drawn from a shared heritage often requires the artist to erase the quotes -- effectively to steal, though often with the assumption that the audience will recognize the material as a reference. Commercial artists usually relinquish this freedom, or more to the point, have their people deal with the thornier issues of attribution and licensing. It remains a point of confusion as to why DJ Quik's label found it unnecessary to secure the rights to a song featuring the voice of one of India's most beloved and instantly recognizable voices. And while the artistic imperative to freely create variations on the work of others must be evaluated separately from the more mercenary concerns of the businesses that exist to monetize that work, in the cases of "Big Pimpin'" & "Addictive", the carelessness with licensing is reflected in the carelessness in which the musical samples are presented. The cultural heritages of Egypt and India become exotic settings for lyrics which glorify the pleasures of either being a pimp or belonging to one.

Both of these songs have since prompted lawsuits making claims on the order of half a billion dollars. DJ Quik's assertion that Lahiri & Mangeshkar had been honored by his use of it was rejoined by an attorney representing their studio's publishing company: "The curses, the sexual suggestions -- these are against the Hindu faith. Their religious convictions have not been honored or respected." In an interview, Lahiri himself went all out and accused those who had sampled him of cultural imperialism. Lahiri, whose

songs include so many flagrant & uncredited 'cover versions' of Western pop hits that they are the subject of several web sites devoted to connecting the dots, is clearly no stranger to musical borrowing himself. But if a charge of mere plagiarism might have been hypocritical, the charge of imperialism retains a sting.

Articles appearing in weeklies, academic journals, and the internet by authors such as Richard Zumh-wawala-Cook and Wayne Marshall have already eloquently described the offensive aspects of entitlement and caricature embodied in these appropriations. One nearly runs the risk of appearing naïve or idealist by arguing in favor of them, by claiming that these are songs that act as works of collage simply by virtue of introducing these intact musical works into the new context of the Western radio airwaves, that music itself always trumps lyrical content, that doors left open to new cultural references not only stay open but invite listeners through them for further experiences. As Tina Chadha quoted DJ Rehka in the Village Voice in 2003, "I see Indian kids in a club who get so excited when these hip-hop songs come on, because for that one moment they feel visible. They don't see the misrepresentations." Those misrepresentations are there,

but they are not seen because they carry less of a long term impact than the sound of the music itself which is now an increasingly accepted feature of the American sonic landscape.

Eric Sermon's 2002 song "React" is a perfect illustration of this early awkward stage in Hip Hop's fascination with non-Western pop music. A song in which the sole purpose of the sample is to support Sermon's boasts of worldwide fame, the chorus drops an interpolation of the Bollywood song "Chandi Ka Badan" as sung by Meena Kapoor. Making a point of being confident ignorance of her Hindi lyrics, he responds 'Whatever she said, then I'm that'. It is perhaps only a beautiful coincidence that the vocal fragment, chosen for its sonic appeal, is actually a perfectly framed sentence: "If a man wants to commit suicide, what is there that you can do?" The degree to which you are indifferent to the range of meaning embodied in the music that you are sampling is literally the degree to which you are only embarrassing yourself. And yet, the result of this chance is a song with multiple authors, an inadvertently profound dialogue that resonates with far greater depth than either the author or the appropriated collaborator could have intended. Historically, collage, as an art form, has a habit of cultivating these exact coincidences and collisions, even now that its practice is largely taken for granted, decades after having been assimilated into the commercial mainstream.

RE-CONCEPTUALISING THE PLAY-ELEMENT IN ELECTRONIC ART

OLLI LEINO

This paper seeks to clarify the ambiguities at the overlap of electronic art and computer games by reconceptualising the play-element evident in both as not only a set of stylistic and creative strategies which we might approximate as “playfulness” but also as a material affordance of a particular kind of audience engagement, which is referred to as “playability”.

INTRODUCTION

The technological make-up and interface conventions of many electronic artworks invite configurative audience practices which resemble those we are familiar with from the context of computer game play. Not unlike the players of computer games, audiences of electronic art can be invited to use, for example, a touchscreen, mouse, or other pointing devices to manipulate audiovisual representations on the screen, perhaps triggering a variety of spectacles along the way. In this light it is not surprising that some contemporary critics have seen it necessary to be concerned about the associations between play and media art. For example, at ISEA 2008, Daniel Palmer, in his paper *The Critical Ambivalence of Play in Media Art*, [9] concerned with media art’s “association with entertainment spectacle” suggested that if “media art aspires to be taken seriously by the broader contemporary art world, the links between media art, children and mass culture are fatal.” Not only do computer games have a certain stigma within the discourse of institutionalized new media art, but the description works also the opposite way. For example, on the online discussion fora devoted to the topic of computer gaming, “art games” is sometimes used as a derogatory euphemism.

While computer games and electronic art have many qualities in common, they are clearly two different cultural phenomena. However, given the hardships that await those who seek to define either (computer) games or (electronic) art, it is feasible here to consider any account of differences between the two as referring not to the qualities of the works themselves but to the institutional, economical, cultural and political conventions and practices that surround the creation, distribution and consumption of both computer games and electronic art. Instead of dwelling on the conventions that separate the phenomena, this paper attempts to see through them into the forms the “play-element” takes in both electronic art and computer games.

BEYOND THE CONFLATION OF PLAY AND ART

In Western thought, the concept of play has always been closely intertwined with that of art: it occupies a central role in many aesthetic theories and over the course of art history, various movements and traditions have made use of ideas of play in different forms. However, we must note that the play of light sought after by the impressionists, the playing of *Exquisite Corpse* by the Surrealists, and finally the activity of play as an engagement in an electronic artwork are all significantly different phenomena, which come together only in a benevolent colloquial application of the term “play”. Sutton-Smith, [11, pp 133-4] who attributes the origin of the conflation of art and play to the romantic parallel between children’s art and modern art manifested in the attempts to appreciate and emulate the “infantile innocence”,

suggests that the conflation obscures “whatever the true relationship between play and art actually is.” The conflation rightly suggests that some of the concepts we may associate with play, like some of those mentioned by Caillois; [2, pp 10-11] freedom, separatedness, uncertainty of outcome, and perception of alternate reality, seem all equally fitting for the descriptions of both artistic and ludic practices. However, if we stick to Caillois’ definition of play (ibid.), we find other concepts, such as non-productivity and rule-governedness, which seem to hold a slightly more marginal significance if applied to artistic practice.

While there certainly is enough evidence to claim that art and play are associated, it is important to bear in mind that the simple concept of “play” masks a variety of practices (some of which we would be better off conceptualizing through the notion of a game) and modes of experience not necessarily compatible with each other (cf. Malaby [8]) . Thus, addressing the play-element in electronic art requires more specificity than what can be attained by understanding “play” in terms of the lowest common denominator in all examples fitting under the umbrella of play and art intertwined. Pursuing this specificity, I shall in the following distinguish between playful strategies and playability, where with strategies I refer to the decisions that an artist makes in the process of creating a work.

PLAYFUL STRATEGIES

Among what we might call playful strategies we have play, or perhaps more accurately playfulness, as a referring to a work’s theme or style. Consider for example the impressionists depicting the ‘play of light’, where the players, assuming whose involvement is a precondition for any significant application of the notion of play, appear as embedded in the work: neither the artist nor the audience are playing, but the work can be described as representing some kind of play (cf. Sutton-Smith [11, pp 135-47]). In addition to play as a thematic metaphor, we can identify creative methods that fall under the umbrella of playful strategies. Here the artist-player’s choices precede the work, and thus the play is not ‘inside’ the work. Consider *Exquisite Corpse*, the Surrealist drawing-game, as an example of a creative method, users of which are engaged in an activity resembling a game, which in the end produces an outcome identifiable as a discreet work.

This description can be applied also on the tradition of generative art, which Gallanter [4] describes as a practice making use of a procedural system which when set into motion assumes a degree of autonomy and produces a work of art. Generative art, in terms of its implementation of rule-based like principles is not unlike surrealist games – the significant difference being however that the procedural system may not need intervention but can itself occupy the position of a player. However, the emphasis on the outcome challenges the applicability of the notion of “play” for the description of creative methods. Following Caillois, [2, pp 43-55] we may observe that the more emphasis we place on the outcome of the game/play activity, the further the activity moves toward its “corruption.” Hence any rationale for addressing it as “play” instead of for example as a value-creating strategy diminishes. It seems that the game-like creative methods that are geared towards producing a discrete result supposed to sustain hermeneutic projects can be distinguished from game/play per se, in which the process itself is the primary locus of experienced significance.

This does not mean simply that some works require a focus on the process in order to be understood. Consider, for example, Allan Kaprow’s happenings. In *Household* (1964), a group of women were asked to lick jam off a car. To make any sense of *Household*, we must begin with the process, as there is no ob-

ject to analyse, but we will not find the locus of significance within the process of the participatory performance of *Household*, but somewhere on the fringe between the process and the discourses surrounding it, including those of theatre and audience. Consider *Tetris* (Pajitnov 1984): while it can be subjected to a multitude of interpretations, inherent significance unfolds from process of playing *Tetris* as it gets underway. The player is presented with a condition that her survival depends on her ability to keep the stack of falling blocks from reaching the top of the container. The *Tetris* artifact evaluates the player's performance and decides whether the playing of the game should end or continue. At will, the player, who we assume is voluntary and thus desires to be a play, can extract a number of value assertions from her condition: for example, constructing unbroken lines of squares at the bottom is good as it keeps the stack from reaching the top thus the player from ending up in the undesirable state of 'game over.'

FAILURE AND INTERSUBJECTIVE SIGNIFICANCE IN PLAY

To illustrate the idea of locus of significance within the process, let us imagine *Tetris* without the possibility of failure, allowing the heap of blocks to rise up indefinitely. From the condition of the player of this game we could not extract the kind of assertions mentioned above. Seeing any difference between the significances of constructing broken or unbroken lines using this or that colour would require reference to outside *Tetris*, not unlike making sense of *Household* requires looking at outside the performance. Playing the ordinary *Tetris*, we soon find out that the colours mean nothing and unbroken lines are good. Hence, we observe that if the possibility of failure is removed, the locus of significance moves outside the process.

The failure here is not a purely subjective failure, as in a failure to interpret or to appreciate. There are works which invite some kind of 'mental play' in their audiences – regardless whether we consider it as "aesthetic play" or as solving a crime mystery depicted in a novel. We can consider these works, like *Tetris*, as using play as a means to engage their audiences, as suggested by Sutton-Smith [11, p.141] regarding "literature of nonsense and humor". Reader of such works, is, according to Sutton-Smith, "immediately at play in an imaginary world of textually incongruous transformations." However, regardless of how we define play, we can observe that the existence of a possibility for a failure on the audience's part distinguishes between the ways in which *Tetris* and a novel use play to engage their audiences: the condition of a reader of a book does not include the risk that some choices lead to not being able to continue reading. Hence, perhaps works which incite 'mental play' would be better referred to as works exemplifying playful strategies.

As observed before, many new media artworks invite input from their audience, perhaps through an interface easily associated with computer games. Often, the audience's choices have consequences in what they see as output from the work. This is similar to how computer games work. We might consider the audience engaged in this activity of input-output as 'participating' or 'performing'. Again, by looking at the kinds of failures afforded we can distinguish these participatory and/or performative phenomena from each other. The failure in *Tetris* discussed previously is not a failure defined primarily by the social reception situation - it is not an ambiguous failure to behave or to use something 'properly,' which might happen in the input-output-situation around a participatory/performative artwork. While the possibility of this kind of failure creates a tension that perhaps contributes to the attraction of "performativity" and/or "participation" in the context of electronic art, it is important to observe that the standards by which the audience's performance or participation are measured are as ambiguous as those suggest-

ing that one interpretation of a novel is better than another. If an artwork is able to evaluate the audience's performance, and decide based on this evaluation whether the audience should be allowed to continue interacting with the work, we can find a more descriptive term with which to refer to it than simply 'participatory' or 'performative'. This term is, I suggest, playability, considered as an affordance in the work.

PLAYABILITY AS AN AFFORDANCE

Playability refers to a work's ability to effect successes and failures on its voluntary users. The criteria for distinguishing a successes from failures are contained in the work itself, not unlike in an "ergodic artwork" which Aarseth [1, p.179] defines as one "that in a material sense includes the rules for its own use, a work that has certain requirements built in that automatically distinguishes between successful and unsuccessful users." However, when referring to computerized forms of play, it makes less sense to talk about rules, as they exist in computer games only through a benevolent reading, at least if we consider rules as they exist in traditional games – as, for example like Huizinga [6, p.8] suggests, something the players have to remember in order to play. If we instead understand these playable artefacts as endowing their audiences with a degree of freedom while simultaneously making the audience responsible for this freedom, we can describe the distinction between a success and a failure with no reference to rules. Failure is the player's choice that led to the material impossibility of continuing playing, and success is her privilege of subjecting her choices to be evaluated by the artefact again. This is what I have elsewhere [7] referred to as the gameplay condition. Thus, in addition to playful strategies, we can establish the concept of playability, referring to a work's affordance of being played. Playability does not exclude performance: the kinds of failures associated with 'performance' and 'participation' and defined by the reception situation, are possible around playable works, which can also incite 'mental play'.

The notion of playability allows distinguishing between works which at a first glance might seem similar – those which invite participation, performance, interactivity, or navigation, and those in which the activity, whether playful or not, is evaluated by the work as described previously. Similar specificity is brought by the notion of playability to the application of the term "navigation" to describe that which goes on between a work and its audience. It allows us to distinguish between works that invite us to navigate merely for the sake of "exploring" the work, and those which specify where to go. The former works, while exemplifying playful strategies, are not playable, unlike the latter. Similarly, while the popular online game *Farmville* (Zynga 2009) certainly is playful in terms of its audiovisual appearance, it does not contain a possibility of failure and is thus not playable. Consider also the Japanese *Konapun* toy set, which we might read as a simulation of cooking à la Frasca [3]: among the behaviours retained from the original activity are for example mixing of ingredients inside containers and setting the finished products on a plate. The standard by which the user's performance is evaluated is arbitrary. A parent might tell a child that her performance was superb even though the dish hardly resembles the one depicted on the box of the *Konapun* set. In contrast, another cooking simulation, *Cooking Mama* (Office Create 2006), is much less ambiguous: not only the player gets a score and Mama either smiles or her eyes glow in fiery red, but unsuccessful cooking attempts prevent the player from advancing in the game while successful dishes unlock new recipes. While both *Konapun* and *Cooking Mama* are simulations, *Konapun* is playful, but not playable, whereas *Cooking Mama* is both.

While the idea of a possibility of failure leading to a locus of significance being within the process itself poses certain challenges for the interpretation of playable works. Previously I have mentioned that the colours of *Tetris* blocks mean nothing, while simultaneously suggesting that if there was no possibility

for failure, we would have to refer to outside *Tetris* to find out whether the blocks have any significance. We may observe that playable works contain the standards for their own interpretation, but in doing so we must remember that the interpretation for which standards are contained is not the only interpretation to be made. Instead of referring explicitly to 'meaning,' perhaps the observation about the colours of blocks in *Tetris* would be better formulated as: treating blocks of different colours differently would not help the player to survive in the game. However, it is important to bear in mind that a successful pragmatic, or, survivalist interpretation of what is going on in a game is a precondition for any interpretation about the game's significance in the larger socio-cultural context. Exploring the consequences of one's choices in relation to failure is necessary before one is able to see why for example *The Marriage* (Humble 2007) has its name.

Playability prescribes a sense of purpose to which any kinds of interactivities (participation, selection, performance, navigation, exploration etc) the work may afford are subordinated. Hence, from the perspective of playability, the actions available for the user of an interactive artwork appear sometimes rather purposeless, not unlike actions in a game of Tetris from which the possibility of failure was removed. While we must note well that the domain to which the concept of playability refers is not the only domain of experienced significance in the reception situation, perhaps the generation of new media art audiences who have grown up with computer games are accustomed to expecting intrinsic significance from the works with which they interact.

CONCLUSIONS

In relation to both Palmer's concern about the links between entertainment spectacle and media we can observe that "playfulness" and "playability" are two separate phenomena, whose coexistence in either electronic art or computer games is accidental rather than essential. Based on what has been said, it should be possible to come up with a definition of "playable (art)works", those from which all the playful "childish" elements are weeded out but which nevertheless subject their users to a gameplay condition. However, assumedly the definition and that at which it would point would be fairly conventional.

While distinguishing playfulness and playability is analytically sensible, it is not to impose a normative agenda of keeping them separate. Especially interesting are those examples in which playfulness as an artistic strategy or a thematic metaphor manifests itself through playability. These we can, following Sutton-Smith [11, pp 147-8], consider as "meta-play", defined as "that which plays with normal expectations of play itself". Galloway's [5, pp 107-126] six strategies for "counter-gaming" are relevant in terms of meta-play, outlining a playing field for meta-play on the conventions of computer games. Another interesting conflation of the playful with the playable is what Ryan [10] calls "dysfunctionality", taking variety of forms. As an example of "politically motivated dysfunctionality", Ryan cites *September 12th* (Newsgaming.com 2005), a game which makes a point by not being winnable. Also Sicart & Wilson's [12] abusive game design strategies, which seek to highlight "the dialogic relation between player and designer" through placing the player in an awkward and/or uncomfortable position, deserve attention as forms of meta-play. In relation to the gaming public's tendency to downplay the so-called art games, we can only remark that while in terms of expressive possibilities of the media, there is room for a variety of artistic strategies for negotiating the relationships between playfulness and playability, the gamers' expectations might sometimes clash with the artistic sensibility of stirring the old in search for the new.

PRECARIOUS FLUX

DONNA LEISHMAN

Mixing theory with applied perspectives this paper generates a series of questions and describes how contemporary social technologies have significantly changed our practical reality, a reality where human experience and technical artifacts have become closely intertwined. The paper's conclusion explores the ontological consequences of this change and the potential in establishing 'Precarious Design' practices and methods as a response.

Samples of the positive social and digital media branding straplines.

Introduction

The physicist David Bohm (1980) posited that the “world is full of movement and becoming, in which any thing, caught at a particular moment, enfolds within its own constitution – the history of relations that brought it here.” [1] This is an intriguing position and one that in spirit captures the inherent limitations of a singularly defined experience and gives prominence to the notion of complexity and “being in flux.” Some years later and based in another field entirely, design thinker and curator Antonelli (2008) opined that “... core human experience is rendered more urgent by the speed at which technology is moving...” and that a great number of us “...routinely live at different scales, in different contexts, and at different settings – Default, Phone-only, Avatar On, Everything Off on a number of screens, each with its own size, interface, and resolution, and across several time zones.” [2] This modern way of existing is often described as appealing, stimulating and empowering. Various social media platforms, digital agencies and technology developers all strive to assist, to connect us through these multiple interfaces and time zones. The corporate/civic/personal rhetoric of social media is driven by the positive (see Fig 1.). However a few notable counter voices have arisen. The Baroness Greenfield inspired a fierce bout of media anxiety in April 2009 after she published an article in the Daily Express titled “How Facebook addiction is damaging your child's brain: A leading neuroscientist's chilling warning” in which she claimed that there were (probably) lasting neurological effects from frequent exposure to social

media websites. Since 2007 there has been increased pressure from the American Medical Association for the American Psychiatric Association to include internet addiction, video game addiction, e-mail/text messaging along with sexual preoccupations in the upcoming 2012 Diagnostic and Statistical Manual of Mental Disorders (DSM – V), the standard diagnostic text used by psychiatrists worldwide, and on the 16th of February this year Physiologist Kathy Charles, writing in the *New Statesman*, likened once again the social network to something compulsive and destructive, claiming that: "Facebook keeps users in a neurotic limbo, not knowing whether they should hang on in there just in case they miss out on something good." This paper will attempt to avoid the techno triumphalism of being better 'connected' and similarly the paranoia around digital media's so called deleterious mental effects on users. An idea that will now be revisited and debated in British parliament after many sections of the British press blamed social media arenas for aiding the London, Birmingham, Nottingham, Bristol and Liverpool city looting problems on the 6th, 7th and 8th of August 2011. Rather this paper accepts that we are now in an age where cultural and technological change has created a new reality of sustained rather than temporary movement. Although Bohm and a plethora of thinkers, scientists and artists have either instinctually known, or through intellectual observation made peace with this worldview, this paper shall explore the problems and potentials that arise when applying such a notion to the everyday user of technology in society.

Context Theory

The majority of users remain uncomfortable around confusion, and if we do encounter it we still expect confusion to be of a fixed and short nature, it's a basic tenet of the knowledge is power aspiration. Human Computer Interaction (HCI) was a field that historically had not been concerned with representing complexity or mirroring the precariousness nature of our existence. Rather HCI's goal was to gain user satisfaction, to make digital tools more receptive to our needs. Media Art arguably has never contained any stable goals or ideologies and is populated by a mix of pioneering creative technologists (Robert Hodgin, Jer Thorp), obsessives (Joshua Davis) and niche collectives (Antirom, c5corp).

There is a danger associated with being in flux, it suggests change, pressure, and movement even Bohm's 'becoming' implies an end rather than an endless becoming. A fundamental of good HCI design was to eliminate or reduce user confusion, to allow us to be stable, to have permanence, to perceive and connected to and transact with the systems and devices that we need. User legibility was preferred over ambiguity. Design thinking was all about making things better a form of modernist 'heroics'. Recent developments in the field have seen a turn towards experience design, described as a situation where experience and technology are intrinsically enfolded. Lucy Suchman an anthropologists specializing in the digital described the "relations of human practice and technical artifact [have] become ever more layered and intertwined. At the same time that the technological project is one of congealing and objectifying human activities, it is increasingly also one of animating and finding subjectivity in technical artifacts. The assimilation of lived experience to technique goes both ways, which only makes the project of re-imagining technological objects the more urgent." [3] This turn to experience with a need for engagement with dense multidisciplinary methodologies will inevitably expose the field to the poststructuralist problem of endless subjectivity. In traditional dialectical tension to Design, Art has traditionally functioned as society's most deliberate and complex means of self-expression and as such is comfortable with subjectivity. When artworks follow anti-hierarchical ideologies (post Dada, Fluxus et al.) a certain level of dissonance can be felt by the user as they struggle to identify what are the expectancies of them given the lack of explicit rules. The ensuing paradigm of uncertainty, ambiguity and ambivalence in early twentieth century Art preceded Bauman's turn of the century notion of 'liquid modernity,' [4] a new

modernity in which fractured timelines were normal, where social structures were no longer stable, and a state of being where fixed concepts like ‘career’ and ‘progress’ could no longer be meaningfully applied.

Context Corporate

Today’s torrent of societal change and unrelenting uncertainty has left many industries sluggish and affected many corporate identities (consider the state of journalism, publishing, music distribution, retail). The speed to change is recognized (no longer new) but many are now feeling the impact of this sustained change. For Designers questions now arise about their role in solving societal problems and how do they confront the idea that a theory of everything is needed, that everything must be considered before anything can be addressed? The traditional path to a clearly defined problem and solution becomes a challenge, perhaps even futile in this period of dense movement and uncertainty.

Context Ludic

Cultural theorist Huizinga (1938) conceptualizing play stated that within a game you are “...spatially and temporally segregated from the requirements of practical life”. [5] Whereas now to be spatially and temporally segregated (from workmates, lovers, family and friends) are now common requirements of practical life. Perhaps there are merits to re – exploring the ludic discourse above and beyond the past the preoccupation with narrative aesthetic and revisit the psychology of role – playing. Role – testing or –playing is expected to be transitional - done in our youth, but within the social network and digital gaming contexts we can extend this process. What happens if you can’t manage our new ‘practical life’? In this scenario what does suspension of belief and or self now mean. The gaming analogy can also be distinctly felt within the observations of Jenkins [6] who described a move away from transactory culture into participation where play is becoming a default method in engagement and knowledge attainment (and almost universally seen as a good thing).

Context Social Skills

Western society has been through an adjustment; we have adjusted to accelerated change, hopefully learned most of the tools required for this new practical reality. Graduating from the novice state towards the intermediate level we psychologically lean on our tools (Charles 2011) to such an extent that dissociation anxiety has become a popularly understood term – describing our contemporary difficulty when we do not have access to our connective technologies. There have been recent attempts at convergence, by bringing together all our feeds, our emails, texts, tweets into one interface. [7] This attempt to unify the users experience is a logical but perhaps anachronistic goal when each media instance fosters a different cognitive connection, simply blending these mental conditions this may not be a unifying reductive solution. We ‘need’ these tools to provide different things for us: acts of sharing (Blog, Twitter, Podcast, MySpace, YouTube, Flickr, Vimeo), discussion (Twitter, Newsvine, StumbleUpon, Youtube) and connecting, re – connecting (Facebook, MySpace, LinkedIn, Friendster) are all distinct practices. Each of these different functions requires significant effort to immerse and different commitments in terms of assessing, changing and publishing content; each interface (after all conceived as a discrete experiences) cues the user into different mindsets. Bringing them all together may result in a useful Meta view of activity but perhaps not in itself a unifying experience that can solve the more fundamental mental and emotional conditions of confusion, noise and anxiety.

Context Depth

Mike Bergman, credited with coining the phrase 'DarkNet' has said that searching on the Internet today "can be compared to dragging a net across the surface of the ocean; a great deal may be caught in the net, but there is a wealth of information that is deep and therefore missed". [8] Intermediate media users can quite effectively create a closed private network of devices used for file and content sharing such as the encrypted messages sent via BlackBerry to various mobs during Britain's August 2011 riots. There is also evidence that users are finding new modes of communication and semantics [9] such as the increase in personally curating our entertainment and nested linguistic meaning. Whereby a message or sentiment is embedded, disguised or hidden within a linked text or video, which can only be truly understood by select users who are aware of the specific total (online and offline) context of the user. The deep and cognitive Web is several orders of magnitude larger than the surface or representational Web. This level of subjective and structural complexity means that the Internet still constitutes a free activity where we can move around, sign-in, explore, search, look, understand and comment without a sense of sanction. What then if anything constitutes expert usage, traditionally denoted as prolonged intense practice through experience and education, in a world full of multiplicitous digital experience? Antonelli (2008) addressed the role of design in a world which humans have surpassed their Enlightenment roles as neutral observers and have become 'actors on the very forces of nature'. Implying that to effective one must be active within the complexity. She also saw a need for users to develop personal elasticity, that being: "the by-product of adaptability and acceleration, elasticity means being able to negotiate change and innovation without letting them interfere excessively with one's own rhythms and goals." This paper also considers if to be expert now means to be agile and surface than deep. Huizinga's (1938) seminal quote goes on to extend the description of games in that we are also "bound by a self-contained system of rules that holds absolutely." As stated acceleration of the Internet and its online culture left the corporate world far behind, conventional advertising strategies were ineffective, the environment was to a large extent unstructured. New rules were slow in coming; what remained meanwhile was self-governance. We explored our user role and sense of self in a freer system of ethics and behavior – many used alter egos, role –playing and exploration of promiscuity and the taboo [10]. What constitutive and regulative rules now control our behavior?

Context Semiotics

If we remain in a gaming mindset, then the conventional wisdom is that life shall intrude, that there is a porous magic circle. In offline, online and everything in-between people are crossing this reality / non-reality threshold all the time in both directions, "carrying their behavioral assumptions and attitudes with them" (Castronova 2005). [11] Practically testing or breaking through the offline and online bubble has resulted in some contentious legal interpretations such as the recent conviction that Paul Chambers received for his 'tongue-in-cheek' tweet about blowing up Robin Hood airport in Britain back in January 2010. A vigorous debate has ensued around appropriate contextualization of Chambers actions. The presiding judge interpreted that "*Any ordinary person*" would interpret the tweet as alarming. [12] The notion of ordinary is now in itself a fraught concept. What is ordinary social insight when at different scales, in different contexts, and at different settings? There are still no clear regulative rules that prescribe acceptable social conduct/communication within social media (the UK Digital Economy Act 2009 is mainly interpreted as copyright protection). The Chambers case shows how problematic words without appropriate context are.

Context Physical

Service design and co–design go some way to addressing the HCI context of complexity but from a procedural and often corporate view. When attempting to congeal and objectify contemporary human activities is not surprising that Design has moved away from an industrial to emotive centered approach. An excellent example of this is the ‘The We Feel Fine’ project (www.wefeelfine.org), an emotional search engine started in 2009 whose goal is to collect the world’s emotions to help people better understand themselves and others. Having come through the other side of dematerialization, re-materialization is also becoming more prominent. The uptake in programming projects such as Processing (Java) and openFrameworks (C++) by non-computer scientists is making engineering physical and digital interaction more achievable (see ‘Pigeon d’Or’ by Tuur Van Balen). Another example of rematerialization is Tim Kring’s augmented reality game ‘Conspiracy For Good’ which confidently attempts to make a virtue out of the game fiction / social reality divide. This paper proposes that such practices could be considered as Precarious Design.

The Precarious Designer

When asked to reflect on the art of the first ten years of the millennium, art critic Hal Foster [13] focused on the ‘precarious’, art which functions as a social – political critique, work which foregrounds its own schismatic condition, its own lack of shared meanings, methods, or motivations, Art if you will, that captured a sense of cultural vertigo and liquidity. Applying Foster’s description, a Precarious Design paradigm could be a community of precarious designers who create experiences and or artifacts from a position of living and observing and testing within acknowledged and accepted precarious contexts. Such a designer accepts acceleration, recognizes the fluxing user position by being one. As with Foster’s precarious art precarious designers can function within a post – conceptual space where there is no distinction between works of self-expression and works of social critique (i.e. they are part and parcel of the same activity). Precarious design by collectivizing or collating works could also give life and voice to the broader fluxing context, objectifying places within the complex digital–physical continuum of our current reality a chaotic continuation of uncertainty.

Conclusion

Both applied and artistic practices are striving to synthesize and express what constitutes a core human experience and develop methods to survive and succeed within our fluctuating context of sustained extraordinary change. In a sustained world of acceleration the aims of design become interesting. If we fully embrace Bohm’s implicate possibilities then, as Suchman writes: “Integration, local configuration, customization, maintenance and redesign on this view represent not discrete phases in some ‘system life cycle’ but complex, densely structured courses of articulation work without clearly distinguishable boundaries between.” [6] User experience should no longer be explored in terms of a singular moment but also over longer periods, or indeed we need to consider that the different interfaces work as differing forms of personal histories. What then becomes significant is establishing what people are actually doing and what people need to do.

Problematically this practical reality is both without perceived sanction and seems to offer limitless individual agency; however, we are not free of corporate or political and legal influence and ramifications.

Users need help in delineating new cognitively useful, safe and or dangerous personal and legal boundaries. Given the cognitive freedom of theersatz ludic space, existence feels quite different. Without rules our identities and ontologies need support. In addition to the recent strategic investment of the designer as facilitator or conduit in multidisciplinary methodologies (Britain's Design Council), this paper offers up the notion of the Precarious Designer, who by way a personal insight via a personal/niche epistemology, is well positioned to conceive of these new expressions and being lighter of foot is able to dance along with the inevitable redefining moments within society and technology.

IN TIMES OF CHANGE: AN INSTITUTIONAL PERSPECTIVE ON COLLECTING AND CONSERVING BORN DIGITAL ART

MELANIE LENZ

The social and networked aspects which permeate the process of making and dissemination for many New Media Art works brings to the fore questions not only about how works are made and used but how they should be collected and conserved. Within the museum context it is the care of the collection for future generations and public access that drives the need for expanded research into the collection and conservation of digital art.

The social and networked aspects which permeate the process of making and dissemination for many New Media Art works brings to the fore questions not only about how works are made and used but how they should be collected and conserved. Within the museum context it is the care of the collection for future generations and public access that drives the need for expanded research into the collection and conservation of digital art. This paper uses the V&A's recently acquired born digital works *Shaping Form 14/5/2007* by Ernest Edmonds, *Study for a Mirror*, 2009-2010 by rAndom International and *Process 18*, 2010 by Casey Reas, as case studies to explore the acquisition, documentation, preservation and the challenges of working in new ways.

The Victoria and Albert Museum is the UK's national museum of art and design. In its early years as the South Kensington Museum, the V&A attempted to unite the arts and sciences. Its collecting policies, which today include born digital acquisitions, continue to emphasise the importance of technique, process and innovation. The V&A's acquisition of contemporary born digital works builds on the museum's existing comprehensive holdings of historical computational work, providing a route for understanding the contemporary significance of early computer artists' work. The V&A received two major collections of computer-generated art and design, one from the Computer Arts Society, London, and the other from Patric Prince, an American art historian and collector. This combined with more recent acquisitions has solidified the museum's status as the national collection of computer art.

The early history of the museum's computer art acquisitions offer important insights into the impact of preservation strategies, the construction of art history and the potential bearing this has for collecting contemporary digital art. The museum began acquiring computer-generated art and design as early as 1969 with the purchase of a portfolio of prints from the 'Cybernetic Serendipity' exhibition held at the ICA in 1968. However until recent years acquisitions ceased, in part due to the difficulties of preserving fragile computer-generated material compounded by, and contributing to the exclusion for many years of computer art by the mainstream art world. The Museum's 2009/2010 display entitled 'Digital Pioneers' sought to redress this and raise awareness of this lesser known field of art and design. The display ran consecutively with 'Decode: Digital Design Sensations', a major exhibition curated in collaboration with onedotzero and showcased the latest developments in digital and interactive design, from small, screen-based, graphics to large-scale interactive installations and new commissions. It included works by Danny Brown, John Maeda, Rafael Lozano-Hemmer and rAndom International. A later prototype of the latter's work was subsequently acquired by the museum; a decision that was informed by the close working relationship between the V&A Conservation Department and the artists.

In May 2010, the V&A acquired *Study for a Mirror* by artist collective rAndom International. Described by the artists as a contemporary 'light painting' it uses face recognition technology with software to transfer the onlooker's image onto the screen. *Shaping Form 15/5/2007* by Ernest Edmonds, acquired in April 2011, is a generative and interactive artwork using software to create a continuous stream of abstract images that evolves in response to external stimuli. Casey Reas, who together with Ben Fry developed the open source software known as Processing, is the latest digital artist whose work has been acquired by the Museum. *Process 18* by C.E.B. Reas is a visual and kinetic system.

The challenge of preserving these works rests on the question of how born digital art can be understood and used in the future when systems, software, and knowledge continue to change. The vulnerability faced by all software-based artworks is its susceptibility to change. The obsolescence of hardware and format, the bespoke nature of the code and the rapidly changing systems and technical environment all pose risks. To reduce these risks the museum has developed a series of steps, firstly identifying what elements need preservation. Through a series of discussions with the artists the museum ascertains the significant properties assigned to the concept, material components, the experience and perceptual quality of the art and identifies which component parts are interchangeable. Details about the code are recorded such as what software the programme is written on and how it is saved. The production path is documented along with information on how to recognise failure detailing what constitutes acceptable and unacceptable changes.

Migration and emulation are the two strands through which preservation is managed. Migration, the process of transferring data from one platform to another, is undertaken at the earliest opportunity and where possible saved in multiple formats. As part of an ongoing migration programme the V&A is currently investigating the feasibility of saving the code for all three case studies on VADAR, the museum digital repository. Changes to the appearance of the original format is a risk associated with migration, thus emulation offers an alternative method involving imitating the original look and feel of the piece but by different means. Where possible these methods are discussed with the artists at the point of acquisition. The current strategy relies on the museum continuing to record as much metadata as possible including descriptive, technical and artist-dependent; developing procedures for the acquisition of software-based artworks; identifying tools useful for preservation and initiating a program to test recovery strategies, recording results over time.

The acquisition of born digital artworks has highlighted the need to work in different and more open ways, drawing on the strength and knowledge from an array of people across the museum, in addition to expanding and sharing expertise externally. The social ideas encompassed in the participatory works and collaborative approaches of the artists have given rise to intriguing questions and new challenges both in terms of preserving, conserving and documenting the concept, experience and physical components of works. The V&A has learnt invaluable lessons with each new born digital acquisition which in turn has informed how the museum operates.

THE CREATIVE IPOD LISTENER

Tuck Leong & Nina Gram

In this paper we suggest that people's iPod listening and their interactions with iTunes software result in experiences that are suffused with emotional, physical and social potential. Listeners can use music in order to manage, enhance or facilitate different situations, affective states, processes or activities. This paper will explore how this is informed by listeners' complex understanding of musical genre and style in their collection.

Introduction

Studies of iPod (and mp3) listening have primarily focussed upon the listeners' wish for auditory control and their attempt to withdraw from public spaces.

[i]

This focus has led to a skewed understanding of iPod listening as being an exclusive and excluding activity where listeners are only interested in their personal listening experiences and their individual auditory version of the world. However, the technology of the iPod and mp3 affords more than just an auditory 'shield' from the world. This paper describes a range of possibilities that includes emotional, physical and social potential when listeners engage with and manage their music through interfaces such as iTunes and while listening 'on the move'. We argue that listeners, through a complex understanding of their music, can creatively design their listening experience according to different situations, use music to manage their emotions and space, and in the process contribute to their sense of well being and adding to their sense of self. But first, we will briefly examine the technology involved and its affordances.

[ii]

The iPod - design and technology

People's listening experience via an iPod or other mobile mp3 players is greatly influenced by the associated design and technologies. Firstly, the compressed size of mp3 files means that listeners can easily carry their entire music collection with them. Although the compression may sacrifice some of its audio quality, listeners can quickly and easily choose the exact track to listen to whilst on-the-move and under different situations. The mp3 format makes it easy to buy and share music, and applications such as iTunes facilitates the organisation of the music according to genre, mood, artist, tempo etc, allowing listeners to create different types of playlists, and to add meta-tags (ID3 tags) to their music. Thus, people's interactions with mp3 when listening to the iPod is very different from the interactions with and listening to analogue music which have previously involved taking either the LP, tape or CD in your hands, placing it in the stereo and perhaps reading on the cover or flicking through the booklet. With the

iPod, listeners manage the music on their computer without having any direct physical contact with the music. Furthermore the possibility of listening using the shuffle mode affects the way we listen to mobile music and the experiences we have while listening. Whether shuffling from different playlists or from the entire music library listeners have less control over their listening thus allowing themselves to be surprised, captivated or even to encounter meaningful experiences like coincidence and serendipity. [iii]

Thus, besides supporting the individual's shielded listening, the affordances of the iPod (discussed above) allow people to not only develop an awareness of their music, but also its social and psychological potential in different situations. In this light, listening is not only about finding your favourite song. People can use music to stage different activities for self and/or with others under varying contexts. Our discussion will present this as the different types of agencies afforded to listeners when using the iPod.

[iv]

The agencies can be described as either having a social function, a mood managing function, or as being connected to an activity.

iPod agency

SOCIAL AGENCY

iPods can be plugged into sound systems for social listening. They are often used at parties where people in turn take on the role as DJ mixing the music from their private music library or using self-constructed playlists that suit the current mood. In more intimate situations, iPod listening can be part of a group activity and be central for the constitution of social situations and collective memory.

" My friends whom I have not seen for nearly a year were visiting. So we were looking at old photos from high school while listening to music that we used to love during that time. My iPod was plugged into the sound system. At one stage Laura pointed to a photo and reminded us that in that photo we are dancing to a Timberlake song and then at the end of that current song, the iPod threw us the same Timberlake song from the photo! Spooky! The coincidence heightened the party mood! We all shouted and started dancing!" (Xana, 2007)

Another example of the social agency afforded by the iPod is found amongst music enthusiasts (both amateurs and professionals). One informant reports for instance how a party band is using drum tracks on their iPod instead of an actual drummer. On their band poster they are promoting and branding themselves by focusing on their unusual instrumentation. On the poster it says: 'iPod on drums!'

Besides allowing for shared listening experiences, the iPod can also be used as a way of developing and communicating one's personal taste in music and in the process, one's personal identity.

[v]

MOOD MANAGEMENT AND MOOD CHECKING

The use of music to manage personal moods and feelings has been emphasised by many (e.g., Bull, 2005, 2008; Leong, 2009; Simun, 2009). Here, we want to examine how this is executed. Researchers usually examine listeners' emotional 'peak experiences', such as whether they are very happy, sad, angry or other strong and easily definable emotions.

[vi]

Under such situations, listeners often know exactly what they want to hear and what will put them in the desired state of mind. Nola explains:

"Lets say that I have a broken heart. That is a classic. [...] Then you can have this empty feeling [...] And you can enhance that feeling and perhaps give it meaning for instance by listening to depressing music and in that way having a sort of cleansing moment or by creating a space that makes sense of the emotion you are feeling. [...] At the same time the music can help to enhance or support any happy emotions. That is amazing." (Nola, 2010)

However, more frequently than not, our emotional states are often somewhere in between these extremes, which makes a definition of the private mood and the subsequent choice of music challenging. Here, we show that under certain circumstances, listeners use the shuffle mode as a way of 'checking in' or locating their own emotional state.

"Walking to Uni to submit my assignment and I had my iPod in my hand constantly pressing forward in shuffle. I am not quite sure how I am feeling and I am using the skip button to try and find a song that fits this mood." (Josh, 2007)

And when listeners succeed in managing moods through their music listening, they are relieved. It gives them a feeling of accomplishment or success:

"It is one of those small victories in everyday life [...] It is not a giant boost of happiness but more like pressing the elevator button and discovering that the lift is already there at your floor. If this happens at the University it is the greatest joy of all. You feel on top of it all." (Frederik, 2010).

ACTIVITY BASED AGENCY

The organization of the music according to mood management is closely connected to the activities that accompany the listening. Often the choice of music will depend on a combination of the current mood of the listener and the activity that is carried out while listening to music. If the activity requires energy the listener can use the music to get in the right energized mood. The iPod user is very aware of these qualities of the music and of mobile listening and this consciousness shows in the organization of the music. One iPod user for instance reports how she listens to her playlist 'Run for it' when she goes out for a run. The numbers on this playlist are carefully chosen in regards to tempo and mood and the order of the songs is organized to fit a certain development in intensity throughout the workout.

Patrick donates blood once every two months and he chooses a particular playlist to listen on his iPod:

“I have one playlist of a classical composer that I listen to when I’m giving blood at the blood bank, cos I can get through a whole symphony in that time, makes the time goes very fast” (Patrick, 2007)

Several informants also use the iPod at the grocery store. One of them is easily affected by the crowd and the noise level of this place. He uses the private soundtrack to shut out the many inputs that characterize this public place. Another listener uses the small breaks in a day, for instance while standing in line at the grocery store, to create positive experiences for herself.

“A lot of people say that they listen to music to avoid wasting time. They think they are wasting time while standing in line in Aldi [a supermarket chain]. I feel like listening to music gives me different experience [...] It cannot make the trip to the supermarket shorter, but it can make it more exciting. It gives it meaning.” (Rocha, April 2010).

As mentioned the iPod can have a practical function for listeners that work with music either professionally or as a hobby. One informant, Frederik, a drummer, uses metronome tracks when rehearsing to help him keep time. Furthermore he uses the iPod to prepare for band rehearsals:

“...And if I am going to rehearsal and I am not prepared, then I can prepare myself using the iPod on my way there” (Frederik, 2010)

The negotiation for music that best fit the activity appears to be learnt through previous experiments and with particular goals in mind.

“When I choose a playlist for work, I need something that keeps it light and kind of happy, bouncy. You don’t want something that depresses you and the customers. For drawing, it’s about keeping my attention focused on what I am doing. For drawing, I am the biggest procrastinator, takes me forever to draw things. So I need some music that didn’t distract me completely. Need it to keep me chained to my desk.” (Xana, 2007)

Our empirical material has also revealed that iPod listening is not suited for every situation. For instance most informants do not use mobile sound media when they are tourists in a new city.

“Let’s say that I’m in Mumbai for the first time. Then I wouldn’t feel qualified to create a space there [...] does that make sense? [...] Well I think by automatically blocking out things from the beginning I would drown the great experience it could be seeing a place for the first time.” (Nola, 2010)

‘Frederik’ also explains how the music can be a disturbing element when you are in a new city. However, it depends on what you are hearing, he says:

“It mustn’t be attention-demanding music. [...]It mustn’t be great art haha...”(Frederik, May 2010)

AGENCY OVER PLACE AND SPACE

By using their iPods plugged into sound systems, some listeners show how they enact agency over their environment – the place and space they happen to be in. This can be related to who else are in the space. For example, Xana ‘broadcasted’ certain tracks from her iPod through the home sound system as

a weapon against her flatmate whom she was not getting along with. This was because her flatmate, Emma watches certain TV shows loudly that annoys Xana. In fact, this cheered her up.

“Thinking about procrastination and how I should be doing work. Also about how stupid Em’s TV shows are. Action: choose music that I know Em hates and play it loudly – so music as weapon of noise pollution. Wahaha!” (Xana, 2007)

Xana also uses her iPod to feel more comfortable and ‘in charge’ of her environment at work. In her new job, she deals a lot of with strangers. So when she was told that she was allowed to bring and play her music at work, she carefully curated a playlist to make her feel in control and more confident.

“I have a playlist with songs that reminds me of happy times, my good friends, family and so on, as well as songs that I know that are popular with most people. By having these familiar songs and being in charge of the soundscape of the shop, I feel more confident when dealing with strangers.” (Xana, 2007)

The creative iPod listener

These different ways of using the iPod bear witness to a new type of listener – one that has a well-developed comprehension of the potential of music and mobile listening. As mentioned the design of the iPod and the ‘materiality’ of mp3 files bring about a different interaction with music when buying it and listening to it. Even though people don’t have any physical contact with the mp3 files, the above examples of the different agencies attached to mobile music listening seems to indicate that people’s relation to the music is as personal, emotional and extraordinary as ever. The physical interaction is now with the iPod. The listeners carry it close to their bodies, and while listening they are often in continuous contact with it as they manage the volume and the order of the songs. One informant even explains how he does this on the move without even looking at his iPod. This familiarity with the iPod suggests intimate relations between the iPod and the listener. In some situations the listeners feel that they need the music in order to be comfortable

Even though there is a bodily familiarity between the listener and his iPod, the listening experience, when using headphones, is very different from hearing music on a stereo or at a live concert. The iPod listener will not have the same bodily reactions of the bass resonating in his chest or the bass drum vibrating through his body. However it seems that iPod listening still engages the body and that the combination of body movements and music are essential to the experience:

“It creates a possibility for contemplation. Partly because the body is activated... like walking to the beat of the music...that is pretty normal, I think [...] 120 beats per minute that fits just right.” (Jeppe 2010)

As mentioned the listening also affects the body by the energy and tempo of the songs getting the listener ready to perform physically or calming him down after a busy day. According to Shuhei Hosokawa (who has examined *The Walkman Effect*, 1984) the body is central to the concept of the Walkman. In fact he states that:

“Whether it is the Walkman that charges the body or, inversely, the body that charges the Walkman, it is difficult to say. The Walkman works not as a prolongation of the body (as with other instruments of musicam obilis) but as a built-in part or, because of its intimacy, as an intrusion-like prosthesis...” (Hosokawa, 1984:176)

Hosokawa believes that the Walkman opens up the body and initiates a process of aestheticisation of urban space. Furthermore the listening process becomes a way of interpreting our selves as the music seems to come from within our own bodies. When applying this notion of a musical interpretation of the self to our current examination of musical agencies it seems to characterise the process of managing personal moods through mobile music listening. By constantly (perhaps unconsciously) evaluating one's personal mood and organizing the music according to one's physical and emotional needs the listener is trained in and becomes familiar with his own reactions to certain situations and to different music genres. The mobile sound media becomes tools in a personal education of the self.

The compressed quality of the mp3 files also affects the role of the listener. According to Jonathan Sterne an mp3 file takes up a tenth of the space of a song on a CD. This extensive compression works because the listener unconsciously fills in any missing auditory information making the music seem the same as when it was heard on a CD or the like. However, somewhere in the middle ear we can detect these reductions in detail and complexity.

[vii]

This change in the quality of the music also affects how we listen. As mentioned many iPod listeners report how they use the mobile music to manage their mood or create memorable experiences in different situations. Nevertheless when they really want to focus their listening and enjoy a piece of music they primarily listen on their stereo at home or go to live concerts.

It is interesting then, how the mobile listening, if it is not necessarily a focused listening, can give the listener strong emotional experiences. The French sociologist Antoine Hennion explains this by describing how iPod listeners construct their own passivity letting themselves be swept up in the music and in the emotion. [viii] So instead of popular music pacifying the listener, as Adorno describes it, the listener actively chooses to surrender to the music and create a personal and emotional experience. As such the listener is very much in control throughout the listening. Even when he himself might describe it as 'losing himself in the music' the experience will often be staged and designed.

This controlled and staged listening can however in some situations influence the experience of situation's authenticity. The listener Nola describes how it feels when she becomes aware of her own staging of an emotional listening situation:

"...and it was like 'uh, now I'm in the country, and it is so beautiful' [...] and then suddenly there was this song, that did not fit in at all [...] and it was so funny because I suddenly realised what I was trying to do, and that sometimes I fail at it, and how ridiculous it sometimes can be, right?" (Nola, 2010)

Conclusion

This paper has presented different ways people exert agencies during music listening through their iPods. We have shown how the iPod is used in many different situations and with different emotional, physical or social needs/agendas. Throughout, iPod users are found to understand implicitly how different kinds of music can affect both their sense of self and its influence over different social situations, whether or not they actually succeed in managing their situation and mood. But regardless of the outcome, the iPod listener is found to interact actively with the music, and sometimes in novel and perhaps

a more unexpected manner. Thus, far from being the listener who is locked and immersed in their sound bubble, iPod listeners are actively involved in their soundscape: creatively tuning, adjusting, and designing a soundtrack that not only supports their sense of self, identity, mood, and aspiration, but also their activities and surroundings.

THE DOUBLE HELIX AND THE OTHER-FRAME

Malcolm Levy

Throughout the history of the camera, a main thread of discussion has been on the mechanical repetition of photography, camera usage, and how aspect can alter, reshape, and change our existing understanding of the tool itself and its usage. 'Other-frames', specifically references abstract frames that are not typically part of the normative captured sequence, offering an alternative methodology within digital photography.

Future Cities, Shanghai, 280"

"No doubt we know less and less about the nature of the image, an image, or the image."

_Raymond Bellour, The Double Helix.

In both painting, and more recently in photography, the conversation around abstraction, with regards to its meaning, creation and place within art, has been an animated one to say the least. Currently, with the advent of digital technology and numerous artistic practices (both digital and film) related to the debate, the discussion has taken on new meaning. One area of study that has been emerging in the conversation focuses on the location at which digital and analog practices meet.

Within this current discourse around Abstract and Concrete practices and Video / Still Image / Photography, the computer chip within the digital camera is an object of much contradiction and beauty. How this small sensor can be manipulated to reveal frames that are in between, or not really part of the actual logical frame rate pattern is both a striking and explosive phenomenon. Through practicing techniques of movement, focus and speed, there is a location where the digital chip stops working properly, where it cannot handle the workload it is being given. The implications of this are the creation of an array of visually abstract stills.

Other-Frames

Throughout the history of the camera, a main thread of discussion has been on the mechanical repetition of photography, the usage of the camera, and how these usages can alter, reshape, and change our existing understanding of the tool itself and its usage. The camera 'chip', or sensor as it is known, based on its makeup and intended action, has only certain processes and actions that it is designed for, in terms of its use. The processes create 'other-frames', specifically referencing frames that are not normally part of the sequence and capture methodology of digital photography. 'Other' in this case lies within its historical philosophical usages of the term not as oppositional, but more so as that which is unconscious or silent.

Techniques with the ability to affect the usage of a digital camera above and beyond the normative practices of commercial video and photography are varied. These techniques exist outside what is considered relevant to the specific needs or usages of the camera with its normative function of traditional documentation. Some of these, based on quick movement, speed and focus in particular, have the ability to create Abstract Expressionist-like formulations out of what could be best described as analogical methodologies within a digital landscape.

The frames live beyond what would be possible in a film reel due to the undiluted analog nature of film in comparison to the digital-analog hybrid form that exists within the digital camera/process. Within the process of slowing down imagery, frames are found that were never intended to exist, and more so, never conceived of as ever being part of the process. In using the chip of the camera, not for its original intended purpose, but for an originally unintended purpose, views beyond the human gaze begin to appear.

The "Chip" itself is an abstract notion. Much in the same way as a synthesizer, the current digital cameras run on mini micro-processors that are then amplified to create imagery. Though the common name for these devices is a chip, they are more accurately referred to as image sensors. In looking at both the CCD (charge-coupled device) or CMOS (complimentary metal oxide silicon) image sensor, what is being created is a mix of analog and digital processes, and therefore reactions and endpoints in creating imagery. The Chip, or image sensor as it is technically referred to is a device that converts an optical image to an electric signal. The purpose of the sensor is to convert light into electrical signals.

As with the sounds that can be extracted sonically from synthesizers and other sorts of outboard equipment, the reaction of the amplifiers in a chip to speed, light, noise, and other exterior factors can manipulate the chip with mystifying results. As opposed to the 'invisible', being that of the darkroom, in this case it is the chip itself, *which is the digitized duplicate of the filmic process of the filming - darkroom process*. The visible process of the camera (dominant action) is pushed aside to give precedence to the usually invisible process (submissive action) of the inner workings of the camera's chip and functionality).

In analyzing the mechanical functions of a camera recording an image, Raymond Bellour investigates the possibilities of abstractions and narratives that can pass through this process. Specifically, Bellour identifies the possibilities for frames outside of the normative process to exist: "This is what, in their way, the words passages of the image refer to. First of all, the ambiguous word *of* includes the sense of between. It is between images that passages and contaminations of beings and systems occur more and more often, and such passages are sometimes clear but sometimes hard to define, and, above all, to give a name to."

These passages and contaminations, as Bellour correctly describes, are specifically, 'Other-Frames'. The digital space within the analog chip, when exhausted beyond its capabilities and capacity for retention, lies very much in the world of the 'in between'. A newly found nature of the image comes through, in this case redefining a space where it didn't exist before. This requires us to question not only what it produces or *could* produce as art, but, above all, to evaluate what becomes of art when it is confronted with a different structure outside of semiotics, and specifically what it signifies (or de-signifies) within its abstracted result.

Bellour referred to this as the Double Helix, specifically the work that lives between the lines of what is foreseen, and unforeseen by science with regard to nature. In analyzing the apparatus, there are two forces, (arguably more) working together to create these new realities, and once the movement of video comes into play, there is the ability for loss of recognition, when the movement is diverted. With the advent of the video camera, and specifically the chip that is contained within it, the abstract nature of what can be created begins to take on a completely different context, both with regard to its final outcome, and the process associated with that outcome.

While the digital process is happening in a video camera, it is really also an analog form, which is why the end result can be so different. This passage, as Bellour refers to it as, is the transportation of the image from the digital to analog space. It is within that space, and through the movements that occur there, that different forms of abstraction can be achieved. "The phases of movement, of false-movement, of passage from one frame to the next, which are very sudden and punctuated with a blue flash, amount to so many outburst of distortion whose effect spreads beyond their own duration; they damage the image we discover, the resemblance that is being created to the point that we are hardly surprised at what is most surprising, and look at it twice before we watch out"

These 'outbursts of distortion' are, in fact, focused on one of the main tools of photographers over time; that which is the dynamic range of a shot being photographed. This has to do with the traditional range of what can and cannot be recorded. This includes the opacity range of captured film images, as well as the reflectance range of images on paper.

The dynamic range of sensors used in digital photography is many times less than that of the human eye and generally not as wide as that of chemical photographic media. In the domain of digital imaging, algorithms have been developed to map the image differently in shadow and in highlight in order to better distribute the lighting range across the image. When images challenge the dynamic range of what can be digitally recorded, the results are in abstractions that can occur within the image.

Video in a sense is the last analog point, or more so the place where the two worlds meet. Video is comprised of analog signals and data, but it is being created and used within a digital capture source. So within video, you have a duality that has grown over time. In a technical sense, we speak of video as having analog data, analogical signals, which is opposed to digital or numerical computer technology; in effect, it is really a meeting of the two. For Olivier Richon, this becomes a matter of reinvention, not only of the tools, but the discourse its self:

New technologies necessarily change the material production and diffusion of images, but what is of interest to me remains the question of the image. The image comes first, not the technology. The binary opposition analogical/digital is intriguing. To use the term “analogical” to define a non-digital photo is now commonly accepted, yet remains paradoxical. Before the development of the digital world of imaging, nobody used the word analogical. There was just photography. There is a reversal here, we can say that at the level of discourse, the digital has invented or reinvented the analogical. The digital needs its other, the analogical, in order to define itself. In a certain way, it follows that the analogical comes after the digital after all.

The practice of generating other-frames is based on what can be foreseen or predicted. Conceptually it is rooted in imagining what is possible based on this transition/passage, of what might be created out of this transference, and the multitudes of possibilities that rest within: “there is still the eye, there are images, quasi images, what one sees, and what one foresees... the computer image is nevertheless on the boundary of an everything-analog whose limits are obviously the creative (or should I say reproductive?) capacity of human movement and the interest that inspires it, with an outcome that is uncertain and stakes that are problematic.” The camera creates an eye of its own, which can be carried out through the actions and movements of affecting it. This uncertainty is a place of limitless possibility for experimentation.

Other-Frames are part of the greater and more profound transformations of the electronic age with regard to the changing relationship of representational imagery and abstraction. Historically the advent of photography as the medium of choice for documentation, created a space for painting in some cases to prioritize formal elements over representational content, creating a vocabulary of meaning derived from colour, shape, texture, and gesture. This space eventually culminated in the movement known as Abstract Expressionism. With the usages of the camera today, this same path is now being taken by a number of photographers and video artists who are coming across the same reactions to our current state of art and documentation.

Living in a culture where cameras have become synonymous with constant daily interactions, (whether this is the news, surveillance, online, urban screens and mobile devices) recording of memory is once again facing the challenges that happened during the shift from painting to photography. As Gil Blank correctly points out around our current state of events: “If ultimately there is anything to be learned from simulacra, it is that we can never in fact separate ourselves from the world or the real.... abstraction, whether aesthetic, mnemonic, or epistemological, is never so complete that it obviates even the

least attempt at a transparent reckoning of history, nor so corrupt that its shortcoming does not in itself offer some model for understanding the human contingency of that same history.

The camera has created a time in history where the impression of analogy has been the object of such deliberate construction, that it has been able to fundamentally question normative practices and certain techniques to the extent that such techniques become the guarantee of a capacity for analogies, the problems of which are posed by the techniques themselves. Continual techniques of the camera, in the same manner as computer software, three-dimensional rendering and other means of visual rendering, are continuing to shift, grow and emerge over time. The construction of the digital-analog space, the process which is undergone in creating this, and the abstract reality that this follows, is in line with the current movements and responses to the constant debate around what can be recorded as memory, and the multiplicity of memory currently.

WELCOME TO ARTOUT - THE FIRST ARTIST ESCORT SERVICE IN THE HISTORY OF ART!

I-Wei Li & Anton Koslov Mayr

ARTOUT furthers the ongoing inquiry into the nature of art production and its economy and test the limits of the “art scene”. Indeed, is “art” an altruistic cultural gesture, a form of business transaction, or both? Or neither?

Fig 1. Artout artist escort, available 450 euro/hr. To book www.artout.org

Fig 2. Artout artist escort, available 250 euro/hr. To book www.artout.org

L'art... peut derivier d'un sentiment genereux: le gout de la prostitution; mais il est bientôt corrompu par le gout de la propriété.

_Charles Baudelaire

ARTOUT artist escort service, launched in Paris in 2006, in many ways is a fruit of a long observation of the art scene both in Europe and in the United States. Between 2000 and 2006, Artout founder, Anton Koslov Mayr, was in charge of an educational project Engarde that investigated the political economy of art through a series of exhibits, seminars and conferences. Engarde primarily focused on the issues related to production of cultural objects and meaning, their consumption and the identity of artists, critics, curators and collectors within a larger framework of the capitalist market system in general and the art market in particular. However, the traditional academic approach upon which Engarde was based demonstrated its limitations, and by 2006 it became clear that any serious inquiry, in order to produce tangible results, demands a more radical strategy. [1]

The ideological genealogy of Artout may be traced to various sources. Mikhail Bakhtin's theory of the carnival, developed in his seminal *Rabelais and His World* is one of them. Performance art as a form of this *carnavalesque time*, in which accepted boundaries and distinctions between reality and representation are subverted (and this is why it is radically different from traditional theater) may be an example. and it explains why Artout has a large number of performance artists as participants and enters squarely into the tradition of "distubational art" to use Arthur Danto's term. [2] Artout may also be put in the

context of *institutional critique* as developed by artists like Andrea Fraser and others. Institutional critique was conceived as a form of commentary of the various cultural institutions and assumed *normalities* of art as well as disarticulation of the institution of art and its various practices. In the case of Artout, it is the relationship between the artist and his/her collector/consumer (both individual and institutional) that is being staged as a performance.

Artout has also been informed by the conceptual art inquiry into the very morphology of art. This inquiry, political in nature, questions the economic dimension of art production, namely the commodity fetish of cultural production, mystification of products and commodification of the artist's personality. At a certain stage of its development, art lost its ability to generate its own definition and, therefore, produce any significant oppositional movement outside of the existing cultural institutions. Creation of culturally significant objects have been turned into an enterprise of creating marketable "novelty"; fetishisation of novelty meant the collapse of the avant-garde since any political opposition to the existing mode of art production and distribution became impossible. In many ways, collectors had become the supreme consumers of "art", its new "aristocracy." The art market imposed total reification of the process of art production, reducing it to manufacturing of objects and events in specifically designated spaces by professionally designated people. Cultural institutions became the superstructure of the market place on which art was being bought and sold like any other merchandise, relying on an all-encompassing process of mystification. This mystification consisted of investing objects with the market value by placing them in the context of art history. Art object as a commodity fetish that offers "art historical value" became an investment vehicle and as such re-affirmed (and continue to re-affirm) a certain economic model with its history of art and its hierarchy of culture. and the entire art market and its adjacent institutional territories became a one big Bernard Madoff collection...

In other words, the law of the capitalist market with its emphasis on the ever-narrowing specialization of labor and maximization of profits invites artists to reinvent themselves over and over in order to escape the market-imposed limits to their identity. This limited identity confines artists to seek satisfying the ruling class demand for the special commodity fetish known as Art and reproduce institutionally-defined ideology of culture. Dercon, director of Tate Modern, even describes artists today as 'zombies and vampires' due to the precarious working conditions they face and endless free services they are willing to offer. [3] In both cases, the producer and the consumer of Art are limited in their freedom by the traditional modes of material exchange.

De-materialization of the art-production process led the rise of immaterial ephemeral time-based art, be it performance, sound or light installation, or simply personalized time. If legal council or P.R. manager's time may cost X \$ an hour, why shouldn't artist's time be valued just as much? The social function of an artist is as important and its cultural message is surpassing anything other economic actors are capable for. Artists are the last ones who are still capable of evoking the real sense of modern tragedy, despite or may be because of their clownesque derisive behavior. [4] And yet, our society treats them as a bunch of extravagant clowns at best, and state employees at worst.

That is why artists must defend their economic interests, their identificational integrity, they must find new organizational forms that must surpass the logic of late capitalism. Artout is an open-end project that is set to operate on the threshold between "reality" and "art" and defies the idea of a designated art space. Artout may very well be a relational project, although, we do not believe that one night-out with an artist can produce a relationship – an enterprise too utopian to be taken seriously. However, we believe that the meaning in art, just like the meaning in a language, resides neither in the artist's intention nor in what he or she does but at a point between the artist's intention and that of his or her viewer

and consumer. Our goal (and/or our product) is to create a *dialogized heteroglossia* that explores an already existing set of meanings, relations, clichés and pre-conceived ideas. By doing so we want to further the ongoing inquiry into the nature of art production and its economy and test the limits of the “art scene”. Indeed, is “art” an altruistic cultural gesture, a form of business transaction, or both? Or neither? Do we have to accept the impossibility of conversation in the same way as it was formulated a decade ago by Michel Houellebecq: “L'effritement tendanciel de la créativité dans les arts n'est ainsi qu'une autre face de l'impossibilité toute contemporaine de la conversation. Tout se passe en effet, dans la conversation courante, comme si l'expression directe d'un sentiment, d'une émotion, d'une idée était devenue impossible, parceque trop vulgaire”? [5]

To conclude, we, at ARTOUT, believe that art is an open concept and artistic praxis is the process of becoming that corresponds to the totality of individual temporality. Artistic creativity results from the dialectical relation between the acceptance of the market as the underlying principle of social reality, and the need to escape its imperatives of obedience and consensus; its locus is the individuality of the artist. The artist plays the messenger and the message, the self-medium that finds its legitimacy through the charismatic negation of conventionality.

We believe that the individuality of the artist is far more significant than the material end-product of the artist's labor. We are extending the limits of the traditional market-model to recognize the artist as the self-defined commodity whose value resides in the immateriality of artist's creative becoming. Spending time in the company of the artist is a new "creative" commodity exchange; it reveals power relations within the existing artist-patron paradigm and leads to the mutual liberation of both artists and art patrons from the condition of simple material production and accumulation to the next level of the direct creative exchange within the dominant capitalist art market paradigm.

Be it in your international head-quarters, or in privacy of your home, offer yourself a true artistic experience! To book, <http://www.artout.org>

NETWORK CULTURE, MEDIA ART: CULTURAL CHANGE DIALECTICS

PATRICK LICHTY

The emergence of Network Culture represents a fundamental paradigmatic shift in society. Networked connection replaces abstraction in terms of cultural production. This paper investigates the influence of Actor-Network Theory as discursive strategy that explicates public spheres such as the New Media art world creating a new form of Virtual social space.

The emergence of Network Culture represents a fundamental paradigmatic shift in society, as it resituates the concept of mediation as a default condition, in everyday life and the art world. Here, networked connection replaces abstraction in terms of cultural production. Actor Network Theory redefines the relations of all elements in a milieu in terms of their effects on the system, and not on their base significations. This results in a heterogenous semiotics of symmetry, where the material, intellectual, and social effects of agents within a network differentiates their degree of agency. This can be seen in terms of Latour's systemic "artworld", consisting of a fractal aggregate of subordinate sites, such as galleries, festivals, websites, and blogs, as well as various overlapping social spheres of influence. This paper will investigate the influence of Actor-Network Theory as discursive strategy that explicates public spheres such as the New Media art world as creating a new form of Lefebrian social space, that of the Virtual. This will be done by considering two New Media art works, *Face to Facebook* and *Wikipedia Art* as examples of cultural production that utilize virtual space as site of social agency under the ANT paradigm.

THE EMERGENCE OF ANT

It has been said that with the rise of network culture, that the shift in focus occurs from the online community to that of the "smart mob"; that this represents a decentering of concentration from the concept of located/dislocated (place-based and place-less space) to that of a flat, relational network. In *Science in Action*, [1] Bruno Latour theorizes the concept of Actor-Network Theory, in which he deals with agents in a network of relations as being *mediated, symmetric, ubiquitous, and material-semiotic*. Ubiquity is assured in that there is nothing outside the network; once someone or something engages an ANT network, it becomes an actant and therefore part of the network. Material-semiosis relates to the actant's relevance having to do not only with its signification, but also with its material circumstances. For example, someone contrasting silk versus nylon hose as social intermediaries would not deal solely with its metonymy as signifying class structure. But taking both as mediators through the material circumstances of silk versus nylon and thus constructing meaning from this as well, these objects become relevant. This is merely to say that meaning in an ANT network is a constant state of socio-cultural mediation and negotiation and is dynamically dependent on the circumstances of the whole network and its architectonic of meaning, rather than merely with its base significations. Latour also states that elements within an AN are regarded as equivalent, or described in the same terms. This includes human, non-human, and material actants, and therefore creates a 'flat' space of signification, and *does* illustrate networks of equal actants, such as flash mobs or online communities (as in our examples), rather than systems that derive difference from less complex sets of criteria.

In terms of ANT, perhaps we could conceive of the network as a heterogenous infinitude of equivalent spaces, but it may be useful for us to consider the nature of constructed space within an AN in order to

consider artworks that engage networked culture. Henri Lefebvre, in *The Production of Space*, [2] posits a unitary theory the division of space into three types, the physical, the social, and the mental. These are derived from Aristotelian “Becoming” to Kantian space to contemporary epistemology as theoretical underpinnings of his construction of space. He critiques Chomsky and Derrida is not addressing the mediation of the “the abyss between the mental space on the one side and the physical and social spheres on the other.” [3] In our case, we would like to suggest that, given the need to bridge this abyss, that we could theorize a fourth space; a Lefebvrian Virtual space as being the combination of the mental and the social. This is the space of our given artworks.

But what of the environment-net they inhabit? To construct an AN within which works like Face-2-Facebook and Wikipedia Art operate, we will look at Howard Becker’s conception of an “art world.” [4] Congruent with ANT, Becker asserts that the work of art is a system within a system which is the product of a set of a complex sociological propositions that are dependent upon one another, which we could consider as analogous to an AN. There is no homogenous “art world” per se, but heterogenous fields of spaces, milieu, individuals, and works. If we allow ourselves to extrapolate to the virtual space in our network, we can see that this expanded artworld exists as a series of overlapping and nested spaces (example, an exhibition is situated by being on a certain website or in a certain gallery, and is then contextualized by the curator and critics, and seen by the audience). There are not just overlapping spheres of museums, galleries, fairs, curators, gallerists, critics, patrons, visitors, but also social media, blogs, forums, maillists, and tweet feeds. Furthermore, our examination of artworld-as-network only denotes the mediated relevance of the milieu (spaces virtual and/or otherwise) merely as construct or our range of interest. The art world, per se, exists within the expanded fields of society, so stated not to imply it existing in social space, but art world as embedded in that larger environment. As such, we could expand the AN to encompass the globe, its societies, all objects, and their dynamic relations. For the sake of discourse, it is assured that this is beyond the scope of our inquiry, and we shall remain largely in the criteria of examining a limited art world network in a virtual space. But even so, we will see that our examples (Face2Facebook and Wikipedia Art) bleed outward from their points of origin into the larger Lefebvrian spatial landscapes.

FACE-TO-FACEBOOK

Face-to-Facebook [5] is a project by Paulo Cirio and Alessandro Ludovico that “stole 1 million Facebook profiles, filtered them with face-recognition software, and posted them on a custom-made dating website sorted by their facial expressions characteristics.” Face-to-Facebook “screen scraped” various data (name, country, groups) along with profile pictures from which a mock dating site called <http://www.lovely-faces.com/>. The artists create a virtual function of agency by harvesting the million faces (social) and processing them to create relations between them (Mental), for a critical Website for wider viewing (virtual agency). Cirio and Ludvico make explicit the theory of agency relating to the idea that facial cues are chosen and used as markers for sexual attraction, although this is a basic metric of mediated relevance in the AN. On Face-to-Facebook, the faces are analyzed using facial recognition software and grouped based on arbitrarily categories determined by the artists, “climber”, “easy going”, “funny”, “mild”, “sly” and “smug”. In Dan Jones’ essay, “The Love Delusion,” [6] states that “men typically overestimate the sexual interest conveyed by a woman’s smile or laughter”, grouping the faces creates a dialogue by implicit discourse of sexual attraction and explicit critique of privacy in social media. Cirio and Ludovico create a critical Actor Network in virtual space as critical device to explicate to make visible the cultural terrain created by social media. Furthermore, the impact of the site on larger networks is shown

by the degree of press the site has created, although this is only a visible indicator of the relational activity within this Actor Network construct.

WIKIPEDIA ART

Another project that plays with differing levels of agency in virtual space is Kildall, Stern, et al's *Wikipedia Art*. In *Wikipedia Art*, [7] Scott Kildall created a performative citation in virtual space as a combination of a mental statement (citation) in the social space of Wikipedia, creating a virtual gesture. It was placed on Wikipedia as "art composed on Wikipedia, and thus art that anyone can edit". Its header reads:

"Wikipedia Art is a conceptual art work composed on Wikipedia, and is thus art that anyone can edit. It manifests as a standard page on Wikipedia - entitled Wikipedia Art. Like all Wikipedia entries, anyone can alter this page as long as their alterations meet Wikipedia's standards of quality and verifiability. As a consequence of such collaborative and consensus-driven edits to the page, Wikipedia Art, itself, changes over time."[8]

This listing lasted for a full fifteen hours until its deletion from the Wikipedia site, but not without widespread discussion throughout communities like Rhizome.org, [9] Art Fag City, [10] The Whole9, [11] and others. The importance of Wikipedia Art was not so much the work itself but its gestural aspect as networked performance that questions the social networks of consensus.

If we could look at Wikipedia Art as an Actor Network, the project would appear as a series of subnets nested within/overlapping one another as a series of spheres of agency or influence. First, the initiators, Kildall and Stern, represent a home node in the network, with rhetorical conspirators (Sherwin, Coffelt and Lichty) representing another sphere. Socially, the project engages the Wikipedia community and the Beckerian art worlds of the Rhizome.org online community and Whole9 and Art Fag City blogs, which in turn have bled to many other venues such as the Transmediale festival and London's HTTP Gallery. Considered as a larger "art world" aggregate, this network influenced the larger society by invoking the rage of Wikipedia founder Jimmy Wales, and gaining notice of the Wall Street Journal. [12]

DENOUEMENT:

While we have explored the concept of ANT, Lefevbre's division of space, and how the two contribute to the construction of "art worlds", the emergence of networked culture creates unique modes of artistic expression. These consist of taking a metacritical role in examining virtual (mental/social) space as medium through the intervention of social media. Face-to-Facebook, Wikipedia Art, Google Will Eat Itself and others probe networks of agency to critically show the shape of networked culture. The fact that it does have a tangible effect reveals the reality of modes of agency within the network, and reveals the critical landscape of the Actor Network.

CONCLUSION:

In closing, this essay has sought to explore Latour's concept of Actor Network Theory (ANT) to describe a paradigmatic shift. That shift is from that of locative/embodied discourse to that of purely networked

culture; that is, the shift from associating culture with places and things to purely that of symmetric networks of equivalent mediated agents. As opposed to the widely conceived hierarchical nature of the artworld, ANT conceives of "art worlds" as conglomerates of spaces, ideas, and social contracts that define milieus and works. Artworks described by ANT critique virtual milieu by engaging artworlds-as-networks, and as such explore a virtual Lefebvrian space by bridging the abyss between the Social and Mental spaces through engaging online communities. These critical pieces explore the relations between actors in social situations in context of "art worlds", with the tangibility of result of their agency being the response in the general audience or public sphere of the mass media. We can examine, using ANT, networked art such as Face-to-Facebook and Wikipedia Art, and as such, describe networked cultural production in its own terms, as demanded by ANT. The rise of networked culture has created a fundamental network shift within society, and ANT is a valuable tool in understanding the relationships created by art within networked social environments, and networked culture as it expands into the future.

NOISE AND TRANSLATION: REMAPPING HABITUS ACROSS THE US/TURKEY BORDER

PATRICK LICHTY

Theorist Gayatri Spivak wrote of the politics of translation as being intrinsic to the construction of meaning if one looks at language as being central to that locus of meaning. Asking the question of why recurrent issues emerge is not enough, but examination of the phenomenology of dialogue between these milieux can lend insight into the experiences of who have traversed spaces which, in their own way, have been everything yet nothing.

Gayatri Spivak wrote of the politics of translation as being intrinsic to the construction of meaning if one looks at language as being central to that locus of meaning. But we can use the distance between root languages (Altaic for Turkish and Anglo-Frisian for English) as metaphor for distance between cultures, to the disjuncture of a notion of home, the translation of meaning, identity, and trans-mapping of cultural mythologies. For many artists crossing into the position of geographical otherness, the issues of translation, dislocation, and nomadism reemerge within the work. How does translation of alterity of space, time, culture and identity evidence itself through the milieu of cultural production? Asking the question of why recurrent issues emerge is not enough, but examination of the phenomenology of dialogue between these milieux can lend insight into the experiences of artists who have traversed spaces which, in their own way, have been everything yet nothing. This is not a space of universals, but a heterogeneous discursive space arising from the shock of dislocation. For our purposes, this disjuncture involves America, the fading center of the world, and Turkey part of Europe, Middle East, and Eurasia and center of Byzantium, the reemergent center of the world. In this paper, we will examine works by Turkish and Anglo-American artists who have either worked, studied, or created in the other country. In doing so, we will explore points of translation, transmapping of meaning, and concurrent cultural threads, not insofar to reduce this matrix of relationships, but to consider points of liminality expressed by the work of these artists. This simultaneous locus of commonality and dislocation becomes the expression of "others" who have themselves been influenced by that "other" place to reflect on their own hybridity and alterity.

As a brief aside, I believe that this process of cross pollination is part of a rich historical conversation over the past 150 years, starting with Osman Hamdi and the establishment of the School of Fine Arts in Istanbul. This continued with the Military Painters, A and B schools of the Early 20th century, who were in dialogue with European artists and schools[1]. More recently, the Istanbul Biennale has been a lively forum for cross cultural conversation, and some argue constitutes a key platform for the emergence of the Contemporary in Turkey. Of note are the Third "Production of Cultural Difference" [2] which expanded its scope under the leadership of Director: **Vasif Kortun** and the Eighth, under the curatorial leadership of ProspectOne curator Dan Cameron. This last instance has led to his curation of the first show at the C24 gallery, the first Gallery in Chelsea NYC that focuses on Turkish Contemporary art [3]. All these events are merely a trajectory of Turkey's interaction with Western contemporary art, and is the subject of a book in itself.

But what are key to the work of many artists working across borders are issues of transcultural translation, liminality, politics, notions of home, and mappings of mythologies, of which we will discuss translation first, which is core to the process of cross-cultural interpretation. Gayatri Spivak, in her *Politics of Translation* [4] writes of the dialectic between logic and rhetoric, where between the regular logical order of words, sentences and paragraphs lie the pauses and gaps that constitute rhetoric. The logico-rhetorical dialectic intrinsic to translation creates semilologic “frayings” that present many risks. These include violence to the subject through misreading and colonization of the other. However, Spivak also posits that the desire to translate creates other discourses. The desire to translate is borne from a love of the subject and as such, creates a space for the cohabitation of the subject and the translator. Even though the translator cannot inhabit the location of the other, the creation of a space in which the translator can attempt to identify or empathize with that other out of love for the subject. This, I propose, serves as a plausible situation for many of the artists here, and as an apologia for any mismappings I may author here.

Another notion that emerges in the work is the notion of home, its construction, habits, and the role that global nomadism plays in cultural production. In a workshop that I co-facilitated at the Cura Bodrum residency on the Bodrum Peninsula in Turkey, the consensus was that we construct the notion of home through aspects of the Heimlich by bonding home to a place, things, or people, like family or colleagues. In addition, home could be ascribed to sets of habitual practices, as suggested by Chicago-Istanbul artist Sevgi Aka.[5] However, this is challenged when individual enters Deleuzian nomadism that moves the body across space, which breaks the hegemonic discourse of boundaries such as those imposed by the nation state. This is in agreement with David Morely, in *Home territories: media, mobility and identity*[6], that describes a “geographical promiscuity” and deterritorializes the individual from practices of language and custom of their point of origin. This creates a liminal mode of being, establishing a space of alterity where one’s identity may have a starting point for its vector of flight, becomes, as Bhabha would put it, hybridized [6] – being an aggregate of experiences accumulated while in the process of motion. It has been said, “We are all aliens”, and perhaps it is the contention of the notion of home that brings this assertion into relief. We are Others when in the other country, but also return as dislocated/deterritorialized aliens as well, or at least arrive less familiar with the implication of home.

Hale Ekinci, in her *Alligator Skin Box: Memoirs of a Young Nomad* [7] playfully intersperses her nomadic dislocation of self through a series of surreal vignettes mixing her experiences in Turkey and Chicago that have existed as online media, single-channel projection, and interactive sculpture. In pre-release versions (not seen here), all her pieces are subtitled phonetically in English, but with the Turkish alphabet. Therefore, “I should do that” would be spelled with Turkish descenders for the “sh” and the like. Stories like her childhood neighbor Arzu distributing bulgur balls out her apartment window and her boyfriend being eaten by an alligator skin box on a bus take on an added disjunctive quality when subjected to the act of subtitling (reserved for foreign movies). It becomes more so when that subtitling is a transcoded/transcultural language barely accessible to either culture. Ekinci is a Deleuzian nomad who has slipped the bounds of her borders, but now inhabits both and neither. But what happens when the communication between cultures shifts to that between species?

Zeren Goktan’s *Aboveground*[8] chronicles the activities of Eastern “pigeon-raisers” who have analogues in Europe and the US, but has very ingrained traditions in the areas she studies. Within the video, the pigeon raisers exhibit great intimacy with their birds, handling them with great care, their hands resembling forms of sign language, signaling a resemblance to interspecies translation. Goktan relates that this avocation is male-centered, although she constantly searches for women engaged in the practice, to no avail. This “hobby”, as the men state, keeps them from what is considered less desirable activities,

such as frequenting coffee houses and playing cards. Furthermore, what is discovered is that this is one of the few spaces in which the men can actually openly love. *Aboveground* examines an expected space of male predominance which is also a site of intimate translation, which is interesting for its relation to its culture as well as its relation to the global nature of the practice.

Iz Oztat's *Reliquary*[9] inhabits another sacred space, that of the reliquary. The work mimics a reliquary of the Prophet in which was related to this author contained a tooth. In this case, Oztat has placed an heirloom seed in the place of the sacred tooth. Such a placement suggests the holiness of the seed in future days in light of genomics, but also calls into focus critical issues of human agency. Placed in context of the referent (an Islamic reliquary) the dialogue of the tooth with the seed calls into question a faith in the Prophet (tooth) with seed as signifier of human agency or holiness of Creation. The question that comes to mind is critical discourses about corporations such as Monsanto and the primacy of nature bring forth a complex narrative, especially when placed in the context of a farm in the Midwestern United States, which is where it was exhibited.

Chicago/Istanbul artist Sevgi Aka's *Gulf Gossip* project[10] is based on the interjection of noise into subsequent rounds of transmission and how we increasingly misunderstand one another with as stages of translation increase, like the classic "telephone game". Based on Baudrillard's *The Gulf War Did Not Happen*, mediations of the event, in this case, depictions of the Gulf War, are reiterated by successive redrawings of representations of Gulf War images. All but one of the participants are female, between the ages of 9 and 81, and the subject abstracts with successive stages, taking forms of nature scenes and increasingly generic affective responses as time progresses and entropy increases. This piece comes from Aka's frustration with global mediation of the subject, with the injection of noise into the mise en scene with successive iterations of retelling, and the commonalities and misunderstandings these communication presents, cross cultural or not. This translocation of information also plays itself out in terms of identity as well as the nomadic individual inhabits the globs and McLuhan's global village of information.

The mapping of information as identity and political representation plays a central role in Ali Mi-harbi's *Delegations*. As the visitor interacts with the piece, which consists of an LCD display and camera combination, they "see a real-time processed image of their faces, constructed using the combination of statistically extracted face features of that country's members of the parliaments." [11] *Delegations* is a representation of political representation as identity of the viewer, framing her in terms of the political landscape of the country of exhibition (Turkey, South Korea, or Mexico). This piece calls into question the fracturing of mediated identity, not only in Donna Haraway's cyborg agglomerate structure, but also the composite identity of the political individual in terms of the place the piece is viewed.

The idea of place is dealt with in N. Eden Unluata's series of books on urban excavations[12]. In this series, Unluata constructs a truly nomadic space, in this case from the artifacts of Paris or Montreal or Istanbul by enacting a series of chance operations for collage within his book-as-doorway. While in the third space (especially Paris), he engaged colleagues from Turkey and the US through Facebook as random number generators so that he could select entries from phone books, video collections, and other ephemera. The door is a liminal space that suggests passage, perhaps for him as much as the visitor-interactor as they peruse the contained videos (via iPod), images, and texts. The *Urban Excavations* are a place where he and the visitor occupy a liminal third space between places by placing all the excavations of place within the door while potentially occupying none. This also is congruent with his audio piece, *Digital Tunnel*, in which he deals with being of mixed birth, and is not "X" (insert identity here)

enough, and chooses to drill a “digital tunnel” into his countr(y/ies) of exile, and exist as a cybernetic nomad.

But when speaking about liminal discourses in transcultural art of artists who have occupied the opposite space, it is important to mention the work of Chantal Zakari and Mike Manden in their book, *The State of Ata*. [13] Manden identifies as American Jewish, while Zakari is Levantine Turk, as signified in their book project, *The Turk and the Jew*, places them at times in a minority position either in the US or Turkey. This fact gives rise to sharp irony when speaking of a famous photograph of Zakari holding a portrait of Mustafa Kemal, (also known as Atatürk, the father of the modern Turkish state) before a Islamist parade in Ankara. The result was a mass media sensation in Turkey, where Kemalist and Islamist positions sought to place the image, and Zakari and Manden with it, as everything from a heroine of the Republic to promoters of Israeli propaganda. However, at a 2011 talk at the School of the Art Institute [12], they stated that the photo was purely taken as a composition for the book *State of Ata*, and the media controversy placed them as a fulcrum between contrasting politics outside their original intentions.

The enmeshing of the political upon the space of the other is no stranger to New Media. American Andy Deck created *AntiWar404* as part of the 2010 Istanbul WebBiennial. As Deck states, *AntiWar404* “catalogs the various anti-war initiatives that have gone offline since the rise of the Web in the 1990s (with thousands of projects started in opposition to wars in Iraq, Yugoslavia, Afghanistan, and elsewhere. But these online media projects have tended to be unfunded and temporary.” [13] The site catalogues these now absent sites in an elegiac move as a global gesture towards cyber-amnesia and the elision of memory in the age of Google. Deck’s sensibility is also reflected in a 2010 interview with Alper Güngörmüşler, Deck reflects on his time as a teacher in Izmir in 2005-6 where the IT department of the university where he taught had banned articles from CNN because they contained the word “nude”. The problem is, as Deck states, that “In understanding how people reconcile themselves with limitations of their freedom and awareness, you can go a long way towards understanding culture and ideology.” This is not to say that the US does not censor certain sites, such as Wikileaks, but Deck’s discourse seeks a comparative dialogue between cultures that shows the ideological terrain of any society through the examination of the disjunctures of what is allowed to be seen and what is unseen.

Another existential disjuncture experienced by cross-cultural artists is that of cultural mythologies, that is the mythology of the other that is brought into relief through the shock of the real. In Mark Slankard’s *Toplu: Landscapes of New Turkish Suburbia*, he documents the emergence of the large-scale residencies of Toplu Konut, beginning in 2008 [14]. Many of these sites are just placed upon empty fields on the outskirts of Istanbul, either in degrees of completion or as neat high-rise condominiums. He also contrasts this with *gecekondu*, or quickly built residencies constructed without permit on public land. The contrast of these sites is stark, and differs sharply from the mythological romantic landscape of palaces, mosques and ruins of Slankard’s guidebooks.

The difference between the romanticized and the real is also illustrated in Patrick Lichty’s panoramic series, *Modern Ruins* [15] captured through composite cellphone images on the Bodrum Peninsula. The sites illustrate construction that he infiltrated during the summer of 2010 which began “on speculation” and then lie fallow when potential buyers failed to materialize the sites. These include unbuilt apartment buildings, similar to Slankard, and hillside villas. These structures merely add to the barnacle-like encrustation of white structures on the idyllic peninsula. *Modern Ruins* Lichty’s extant work with sub/urban sprawl and juxtaposes it with the idealized landscape of the Classical ruin. In the body of

work, there is also the 400 B.C. Bodrum Ampitheatre behind chain link fence contrasted against an abandoned contemporary spa, giving an abject read of the projected image of the romanticized ruin, and in part, correlating it to narratives of global millennial sprawls.

Conclusion

Upon engaging this topic, I realize that there are many more artists that could be included, and that many more dialogues could be engaged. The threads of inquiry discussed herein are only a few of a complex skein of interaction for which an entire thesis could be written. Furthermore I would like to be self-reflexive and problematize my propositions and artistic correlations as possibly being coincidental or merely results of the human condition. Ascribing commonalities to large sets of works using just the parameters of cross-cultural habitation runs the risk of conceptual colonization. However, I would like to argue that although heterogenous, I believe that there are effects of cross-habitation that have created certain discourses in these artists work, and reflect the cross-pollination between our cultures, however directly or indirectly. The cultural differences between Turkey and North America represent a degree of alterity to one another that the impact of the other and the translation of experience is a transformative one. In this essay, I have considered the issues of translation, alterity, identity, the notion of home, and mythology as touchstones on a much larger conversation of commonality and difference. Global society and recent economic and political situations events are bringing the US and Turkey closer together. As curators like Cameron and the artists in this essay explore the transcultural space between our two regions, this cultural exchange will not become only useful, but necessary. It is my hope that this exploration yields useful insights into the trans-art of the dialogue of US and Turkish cultures, and such a dialogue will grow and bear much more fruit.

PHANTOM LIMBS: AFFECT AND IDENTIFICATION IN VIRTUAL PERFORMANCE

PATRICK LICHTY

In the concept of a “phantom limb”, an amputee relates feeling, often pain, from the absent limb. But in the era of ubiquitous mediation (the fin de millennium), embodied expression itself has become a site of contestation. What can be said for the veracity of a mode of expression when the traditionally conceived distinctive qualities of that medium are removed? What happens to embodied art when the body is removed?

In the concept of a “phantom limb”, an amputee relates feeling, often pain, from the absent limb. The process of amputation delineates the borderline of presence, the liminality of separation, the phantom effect the feeling for that lost presence. Performance art inscribes space with presence, with flesh, bone, and sinew; wasn't it supposed to be a final authentic site of immediacy and authenticity in art following the dematerialization of the object in contemporary art after Formalism in the 1960's? But in the era of ubiquitous mediation (the fin de millennium), embodied expression itself has become a site of contestation. The body had become the repository for direct expression in art with the coming of Performance Art. With the recontextualization of seminal works by Marina Abramovic with her *Seven Easy Pieces* [1] the meanings of the works as immediate, site-specific happenings became circumspect. This was further compounded by artists Eva and Franco Mattes, self-proclaimed “haters” of Performance Art, who remediated other seminal works, including those of Abramovic in the online virtual world Second Life. What can be said for the veracity of a mode of expression when the traditionally conceived distinctive qualities of that medium are removed? What happens to embodied art when the body is removed?

Virtual performance art should not function, but it does. The process of draining the site of performance through decontextualization then disembodiment should have destroyed the event of meaning. Where there was blood, there are now only pixels. Where there was presence, there is only the feel of a mouse in the hand. When the avatar shoots the other with a gun, we still flinch. What are the qualities left that connect us to the when avatar when we sever the flesh from embodied performance? I posit that there are three aspects to performance that remain after the virtualization/removal of the body in the creation of virtual performance. These are affect, desire, and mirroring/identification in relation to the avatar. These correspond to the prepersonal, productive and neurological identifications with the proxy. This presentation will explore a phenomenology of affect, desire and identification in the virtual and discuss the importance of these qualities as intrinsic criteria of synthetic performance.

1: Affect

Brian Massumi, in *Parables for the virtual: movement, affect, sensation* speaks extensively on the autonomy of affect. “Affect is the virtual as point of view” [2 Massumi, 35], he says, relating to his assertion that the virtual begins with the event that is too immediate to be perceived, and thus elicits that event's autonomy from the body. What is happening in the site of virtual performance is the precognitive conversation of “the simultaneous participation of the virtual in the actual and the actual in the virtual, as one arises from and returns to the other.” The virtual as site of immediacy begins in the moment of the imperceptible, opening the synesthetic space of autonomy (from the body) while retaining the intensity of the moment. Affect implies, “a participation of the senses in each other: the measure of a living

thing's potential interactions is its ability to transform the effects of one sensory mode into those of another." Can we say that this potentiality is the precursor to emotion, to identify with the potential of a living thing's interaction with a *mise en scene* (through an avatar?) One axis of virtual performance's efficacy is the disconnection of affect from the body as eliciting of synesthetic effect, suggestion that affect may have more to do with action and intensity, perhaps evoking desire, which brings us to Deleuze.

2: Desire

Second Life is an online 3D multi user virtual environment, or MUVE, that owes its existence to the aggregate contributions of tens of thousands of online participants, who construct the buildings, socialize and perform in virtual space. In *Anti-Oedipus*, Deleuze and Guattari posit that desire is not to be linked with the gaze, or signification, but with production in the social field. The avatar represents, by its very existence, an evident desiring-machine that, through its production of virtual capital in the form of artifacts, buildings, codes, and interactions, manifests reality through the consummation of desire via material and social expression. As affect and its translation into the virtual is opened by the preperceptive moment, it is the unconscious and the libido that are the engine of desire. But in their text, their deconstruction of desire signals the aggregate Body without Organs that assemblages of desiring machines, which then represent, "the nonhuman sex, the molecular machinic elements, their arrangements and their syntheses, without which there would be neither a human sex specifically determined in the large aggregates, not a human **sexuality** capable of investing these aggregates" [3 *Anti-Oedipus*, p. 294] It is this nonhuman sexuality of the desiring-machine, the Krokerian "sex without secretions"[4] that then creates an effusive concrete production in the virtual. From this, we can say that the production of the aggregate world of Second Life is a desiring-production in the virtual socius that is product of the deanthropomorphized libido. As such, it begins with the birth of the avatar, manifests in the production of the virtual world, and is consummated in the performative gesture of everything from the cocktail party to execution of code to virtual (machinic) sex. Therefore performance art in Second Life could be said to be the production-manifestation of desire made manifest in the virtual. And to playfully quote the Arthur and Marilouise Kroker, "How could be otherwise?" It appears that the desires of the machinic mirror the body to some extent and this is the next subject of our discussion. 3: The Mirror Cortex

We have discussed the issues of the affective and desire, but I would like to return to idea of the phantom limb metaphor and the identification with identification with the avatar. As there are times when a person with phantom limb disorder can be soothed through seeing a limb be massaged, there are theories that humans empathize with human-like forms through neurological empathy, Neuroscientist VS Ramachandran has popularized neurobiological research of the existence of "Gandhi Neurons"[5] or what he calls the mirror cortex. These neurons are thought to be the basis of many aspects of human existence, such as empathy, learning, and culture. Mirror neurons fire in sympathy with the observation of another person's action. One thing that is ironic that Ramachandran uses the metaphor of watching a virtual reality simulation of the other person's actions, and this brief aside is the opening for our discussion. To put forth the idea that we identify, empathize and project action or touch through the engagement of the mirror neurons, and the idea that we simulate action and touch through projection through perception is very important. To do so explains empathy for the other in a performance space, but in our case, the projection of the self upon proxies such as dolls or avatars. Where this is shocking is when we consider Ramachandran's example of soothing phantom limb pain by massaging another's limb by proxy. What I propose is that neural identification through the mirror neurons is a fundamental cognitive act mitigates performance, and also translates to proxies and poppets. For the next section of this essay, we will look at examples of virtual performance that will attempt to illustrate aspects of affect, desire, and mirroring.

Sites of Engagement: Affect

Saveme OH [6] is a Dutch virtual artist who works in invective and narcissistic grandeur reminiscent of the New Media artist formerly known as NN, who often dominated listserv traffic on lists like Nettime and 7-11[7]. Her art, as mentioned before, consists largely of narcissistic excess through the colonization of the space around her, whether it involves declaring herself “President” of Second Life or imposing herself verbally or visually into situations, often getting her banned. In reaction to bans, Saveme’s reaction is frequently to stage an outcry about censorship. Her strategy is a cross between “trolling” (disruptive aggravation) and tactical intervention, but her tactics inflame an immediate affective response. This is due to the fact that Saveme’s visual appearance often dominates an entire screen through use of huge “worn” devices that create an optical disruption that open the door for her virtual psychodrama. What is most important here is that her domination of a milieu creates a synesthetic disjuncture where there can be no other focus than her gesture and the potentiality of action, engaging affective reaction (albeit frequently negative).

Another group of artists that have elicited an affective immediacy in virtual spaces is that of the performance group Second Front. Founded in 2006, Second Front are a dispersed set of individuals ranging from San Francisco to London who engage in NeoDadaist/Fluxus-based interventions in Second Life. For a piece entitled “Wall-ker Art Center”[8] (or *Dancing About Architecture*), Second Front appeared with huge cement walls, disrupting the visual field, where they engaged animations to gyrate the structures erratically in space, creating an architectural performance. The result was a disorientation for many on-lookers, as the ephemeral walls swung around, appearing to hit the avatars, but passing through them. An anecdotal report during the performance related that the experience was jarring to the point where they had to “teleport” out of the space because of the visceral reaction, reifying Massumi’s assertion of translation of sensation in the affective. Both studies depend on the virtual as point of view and utilize the immediacy of the visual to create effects that translate into the visceral. This bodiless visceral reaction brings us to the site of desire.

Sites of Engagement: Desire

It could be said that using the Deleuzian model of desire, manifestation of being in Second Life is self-sufficient for the description of efficacy of the avatic desiring machine as engine of production or signifier of the libido. To expand from Deleuze, desiring-production is not making love to become one, or two, but thousands. The fecundity of the Body Without Organs, literally or semiologically, is to unchain the repressed libido in revolutionary fashions that the flesh can never attain. This unfettering of the Freudian unconscious takes place in two pieces, Eva and Franco Mattes’ *I Can’t Find Myself Either*[9], and various incarnations of avatar Vaneesa Blaylock’s installations. In the first of these two, as part of their *Synthetic Performances* they suggest that the infinite gesture of becoming is to stay at home and play video games, like Second Life. In this piece, a bed with embedded sexual animations for is activated in the performance space. Eva and Franco’s avatars gyrate on the bed, and soon other avatars join in the cyber-orgy. Soon the bed is packed, and the avatic bodies obscure one another to the point where the piece’s name comes into play. No one can find themselves, but there they are. And, the gesture of the Body Without Organs on screen belie that the avatar is no one and yet everyone, the production of a null body implies the birth of all possible bodies in the virtual.

Another artist who explores the multiplicity of production in virtual space is that of Vaneesa Blaylock, whose name closely mimics that of performance installation artist Vaneessa Beecroft. Her motto is that she is an individual, and so is she, suggesting a self-reflexive stance about her multiplicity. Much like Beecroft’s installations of nude bodies in gallery spaces, Blaylock stages arrays of nude avatars in space under some sort of framing mechanism, Various pieces[10] explore general topics of identity and

cloning, the average parameters of avatars in Second Life, “the girl next door”, and replication of form as production of desire. In each installation, Blaylock arranges the avatars as manifest desiring machines in the unfettered frame of the virtual, inferring that her production is but a sample of infinite permutations and endless emanation. The nude avatar, as signifier of basic sexual desire is here emptied and used as a proxy, a placeholder for our own projections of desire, but since they have been machinized and dehumanized, they stand for an infinite space of nullified machinic desire, and infinite fecund potential, potential being essential for affect. Vaneesa’s installations also engage the doppelganging the body in configurations like Beecroft’s, which takes us to the idea of Mirroring.

Sites of Engagement: Mirror

Macarthur Foundation Director of Connie Yowell said at the 2007 Second Life Community Conference that the first move into the virtual is recreation of the real, called orienteering. Performance artists like Scott Kildall, and again, Eva and Franco Mattes have done “remediations”, or restaging of classic performance art pieces. In Kildall’s *Paradise Ahead* series of recreations[10] include Chris Burden’s Shoot, in which he allowed himself to be shot in the arm in the gallery, or Yoko Ono’s *Cut Piece*, in which she allowed her dress to be cut away a piece at a time. But these are not merely recreations, but empathic mirrors of the gallery, as Ramachandran might argue that we will still feel as Kildall’s avatar fires the virtual rifle, there is a still a flinch when the other avatar is hit. This is not mere signification, if neurological mirroring applies to proxies of the body, then our feeling for the virtual phantom limb of the avatar is real.

The eponymously named AM Radio recreates pathos in the recreation of a trompe l’oeil of David’s Death of Marat[11]. The original, which depicts the radical French journalist Jean Paul Marat dead in his bath after being murdered by Charlotte Corday is recreated sans the body of Marat, upon which the visitor clicks upon the bath, and their avatar fills that position. Therefore the projection through the avatar is further extended into the David painting, specifically into the position of Marat. Here the interactor becomes the subject of, as Baudelaire mentioned, David’s “drama... vivid in its pitiful horror”. This scene’s abjection and the user’s requirement is not isolated; its requirement to participate affectively projects the self into that horror and peace concisely.

Site of Engagement: Affect/Desire/Mirror

Although we have examined sites of engagement that have dealt with the unfolding of Massumian affect into the profusion of virtual desire to the projective identification of the mirror, there are many virtual works that address any and or all of these modes of engagement. Micha Cardenas and Elle Mehrand’s *Technesexual*[12] performance engage all three loci of this discussion. *Technesexual* involves the two engaging in erotic acts in a physical space while equipped with biometric sensors. The output from these sensors is fed into Second Life through an interface using the programming language Pure Data, which is reflected in actions by their avatars in Second Life, which are projected in the performance space. As Cardenas and Mehrand play on stage, they engage the immediacy of the body and the affective lag of translation into Second Life, virtualizing their acts. Their unleashing of the libido into the machinic body creates a manifestation of desire-production in the virtual through gesture and translation of the physical into the virtual and the transmission of that experience to the online participants. And lastly, their doubled bodies, both in world and in the performance spaces powerfully create the projective connection between the two, and the connection of virtual space. Perhaps the introduction of live bodies into the milieu either negates or amplifies the argument for performance in the virtual, but from this author’s perspective, *Technesexual* appears to consummate (metaphorically and literally), affect, desire, and projective identification, and is the pinnacle of the elements of our conversation.

Denouement

In this essay, I have sought to construct an argument for the understanding of affective engagement in the genre of virtual performance through the thought of Massumi, Deleuze & Guattari and Ramachandran as played out through the work of many artists. This is not to say that there are not other artists who also fit this discussion, like Joseph DeLappe's Gandhi project[13] and Stephanie Rothenberg's work in virtual labor[14] and Elif Ayiter, Selavy Oh, and Max Moswitzer's collaborations in virtual textuality with Roy Ascott[15]. The choice of works in this essay are merely a brief archipelago designed to create an epistemic arc to explore the visceral connection to the virtual. There are far more examples to me touched on, and this presentation is designed as the opening note of an ongoing conversation regarding virtual performance.

Conclusion:

By all rights, we should not care about virtual performance as performance art is intrinsically tied to the body as last bastion of creative authenticity. Upon severance of the flesh from the performative gesture, it would make sense that our affective relation for the virtual body should cease. But our phenomenology of virtual performance through affect, desire, and projection suggests otherwise; virtual action creates real responses. In this text, I have sought to explore the role of affect, desire and mirroring-identification with the avatar as evident site of engagement. Although the case for virtual performance's connection to the flesh through our desires, projections, and empathies, it is easy to hold these forms circumspect. Is virtual performance new enough that it constitutes a nostalgia for the flesh, and echoes of the body as phantom limb, or merely grown up poppet play? One could argue that this genre is a fetish for performative dollplay, but regardless, virtual performance contains a combination of echoes of the real and real affective response. This is seen from phenomenology to prepersonal cognition to neurology. Our affect for the avatar exists, and it appears to be acculturated and hardwired into our beings. But as genres such as MMO's and virtual environments like Second Life continue to mature, it will be curious as to whether virtual performance will be a momentary affectation or an emergent genre that merely reflects the virtual as a primary mode of human existence.

ENVELLA: MAKING SPACE PERSONAL

Henry Lin

The paper describes enVella, a kinetic dress that moves when triggered by the detection of the wearer's fear or anxiety. The aim of this project was to investigate the detection of fear with biosensors, and to see whether an enveloping physical transformation can provide a sense of comfort to the wearer.

enVella open and close comparison, 2010, Mark Coleman, Emily Ip, Henry Lin, Alice Ling, Laurence Man, photographic media, Copyright 2010 Henry Lin.

INTRODUCTION

enVella is a kinetic dress which moves when triggered by the detection of the wearer's fear or anxiety. The upper portion of the dress is encircled with fans, which open and envelop the wearer if her body temperature and heart rate are both rising. The aim of this project was to investigate the detection of fear with biosensors, and to see whether an enveloping physical transformation can provide a sense of comfort to the wearer. The paper will begin with the inspiration behind enVella, discuss its design, and conclude with the technical aspects of the project.

INSPIRATION

enVella draws inspiration from the natural world specifically with regards to animals' reactions to fear and the idea of engendering feelings of safety in human beings. An experience everyone has in common is that of being in a mother's womb. In a warm, enveloped space, one feels safe, warm and protected as if one was inside the mother's womb. [3] Despite not offering any real protection, we instinctively huddle under a blanket when frightened.

enVella's motion was inspired by the frill-necked lizard which is capable of erecting a normally-concealed frill from around its neck. This physical transformation makes the lizard appear larger than it is, and so a less appealing prey. [4] By merging this reptilian defense mechanism and the soothing of envelopment, the hope was that this combination would produce a comforting psychological reaction in the wearer during anxious moments.

DESIGN

In an attempt to recreate the sensation of being enveloped inside the mother's womb and implementing the frilled-neck lizard's self-defense behaviour of increasing in size towards wearable technology, this adventurous application explores the concept of embodiment where the dress and wearer engages in a symbiotic relationship. In order for enVella to achieve its full potential, the dress must be worn for it to react accordingly with the wearer's emotional state. Without a pulse, the dress cannot achieve its full potential and without the dress, the wearer will not be able to experience the safety, comfort and protection provided by enVella.

enVella is designed on a white cotton dress attached with four servo-controlled fans. Each fan is constructed of satin fabric folded in half multiple times, and held in place by heavy duty double-sided fusible interfacing. Wooden supports were added onto the ends of each fan to provide motor and anchor support. At the base of each fan, a servo attachment was glued. The fans are triggered by a combination of the two sensor inputs: a heart rate monitor and a temperature sensor. If the wearer's current heart rate and temperature is greater than a predefined average heart rate and body temperature, the fans will open – beginning at the chest then around the neck in a sequential manner (Fig 1). With the fans in their opened form, heart rate and temperature data continue to be relayed from the sensors to the microcontroller. If both heart rate and temperature return to normal after 20 seconds, the fans will close.

The core element of enVella was inspired by animals with distinctive self defense reactions such as the frilled-neck lizard. Through user studies, few design forms were determined as most effective at enveloping the wearer and embodying the idea of comfort and warmth. The four fans were strategically placed and programmed to optimize the enveloping experience. When a state of anxiety or fear is detected by the microcontroller, the fans will open in smooth succession. Because enVella is a dress designed to comfort the wearer, the decision to have the fans open was to create a sense of division between the wearer and the frightening, threatening entity. This invisible wall creates a psychological barrier between the two and thus alleviating some of the resultant fear. A gradual enclosure of the space around the wearer's visual field, rather than a sudden one, adds to the comforting quality of the motion. Whereas if the fans were to open rapidly, it would have an opposite effect on our intention of comforting the wearer.

TECHNICAL

Among the technical challenges present in enVella, detecting and identifying fear was the most difficult to justify through biosensors. One challenge was to find a suitable solution to distinguish fear from other strong emotions like anxiety and anger. Fear is generally differentiated from anxiety by the perception of a specific external threat. However, for our purposes, it was not possible to distinguish one from the other as anxiety and fear have almost identical physiological symptoms. Typical physiological responses to fear and anxiety elevated heart rate, increased sweating, and increased blood pressure. Both the input of heart rate and body temperature were chosen for the purpose of this project, as an indication to measure state of fear. Various heart rate monitor circuits have been developed with Arduino using different methods but the majority of implementations use the Polar RMCM01 Heart Rate module. The Polar Heart Rate Monitor Interface (HRMI) was selected given the added difficulty of working with the bare module. The multiple interfaces available in this new module make it very stable, flexible and easy to work with.

CONCLUSION

enVella project designers witness the success of the dress and how it achieves envelopment through the natural motion of fans. User feedbacks have been positive, with the majority stating they found the enveloping effect comforting. A few participants raised possible issues with the feasibility of a cloth dress offering sufficient protection, and concerns over providing comfort without actual protection. Participants also mentioned possible discomfort and unease that may arise from users who are claustrophobic. Through academic research, the team on designs inspired by nature and explored various forms before finalizing on fans to create temporary personal space. enVella is not only a dress but is also a concept to assess the research question of creating personal space in a state of fear.

CREATIVE ZEN LEARNING SPACE AND COMMUNITY

JIUN-SHIAN LIN, CHI-HUNG TSAI, SU-CHU HSU, CHIA-WEN CHEN & YU-HSIUNG HUANG

We describe a creative Zen learning space built on interactive technology, digital art, and installation art, including three parts “zen_Sit,” “zen_Move,” and “zen_Circle.” It allows any place, any time, ubiquitous Zen – with mindfulness and meditation exercises for concentration, sitting meditation, and walking meditation. It supports the beginning of a digitally-enhanced Zen community.

PREVIOUS WORK

As mentioned above, interactive multimedia technology has been used widely in a variety of artistic, educational, entertainment, and industrial applications. (Space limitations prevent us from giving a full survey.) Particularly important for developing our work have been the technologies of chat rooms, smart phones, and wireless sensor networks.

- Chat rooms: Our creative interactive meditation space uses chat rooms as a simple solution to scalability and mobility issues in zen_Move. Chat rooms are fairly widespread across the Internet and serve a broad range of entertainment and information dispersal applications. Some exemplary application fields are defense; [1] entertainment; [2] and educational study assistance. [3] Below, we show how we used chat room technology to create a communication mechanism across a sequence of computers in the zen_Move meditation environment.
- Smart phone remote control: Our creative interactive meditation space uses smart phones as both remote control devices and to present interfaces supporting “meditation anytime and anywhere” in zen_Move. Control applications using cellular telephones have become widespread, through ad hoc Bluetooth networking, [4] and as remote controls for a variety of appliances. [5]
- Wireless sensor networks: Wireless sensor networks (WSNs) have been widely deployed in a variety of applications including national defense, health care, environmental monitoring, industrial control, etc., [6,7] but only rarely have found use in fine arts. A major exception is Intelligent Interactive Museum [8] which used ZigBee wireless sensor networks, interactive technology, and content management systems to create a museum environment which dynamically adjusted content according to participants’ gender and age. We used WSN technology in zen_Circle and zen_Sit.

Two notable applications of multimedia technology to support meditation are:

- The 2003 installation *ZENetic* Computer created by Japanese researchers Naoko Tosa and Seigow Matsuokam. *ZENetic* Computer transformed traditional meditation content into multimedia to teach meditation practices and guide participants to feel and learn meditation through computer systems. [9]
- *AltarNation* created by US artists Michelle Hlubinka and Jennifer Beaudin in the wake of the 9/11 terrorist attacks. The community created a multimedia prayer room in each member’s home and networked them together. Members could share thoughts and emotions with other remote members and console each other by lighting memorial candles, praying, etc. [10]

In contrast to the above systems, our environments teach mindfulness exercises via interactive meditation environments with a focus on walking meditation; with the ultimate goal of helping participants approach the ideal of treating every moment as a meditative moment.

ZEN_MOVE

zen_Move is an interactive installation environment installed along a corridor at DDBC that allows participants to use ten touch-screen computers to engage in a mindfulness exercise. As Fig. 1 shows, zen_Move is public installation deployed in a linear design with visual effect. As participants move from screen to screen to follow the exercise, they are encouraged to pause and practice mindfulness exercises.

SYSTEM AND INTERACTION SCENARIO

zen_Move uses a long wooden box embedded with ten touch screen computers, wireless network cards and a cover permitting ventilation and access for maintenance. Using a chat room as a tool to support scalability and mobility, we have built a smart-phone version of the application that can be exercised in any location, but further, it remotely triggers the installation.

Participants attempt to move a “Zen ball” (the red dot) along the basic line showed in Fig. 2. The Zen ball is surrounded by a traditional calligraphic Zen symbol representing emptiness – a circle which is the touch sensing area. The participant interacts with the Zen ball using a finger. This involves a careful exercise in which the participant must guide the Zen ball with a finger along a base line at a uniform rate without deviating from the line. After extensive experimentation, we set a time limit for movement on a single screen at 25 seconds. We calculate a focus index (using a function determined by statistical analysis and experimentation) from the horizontal movement along the baseline and any vertical offset from the baseline. The focus index shows how smoothly and accurately the participants manipulate the Zen ball. Depending on the focus index the participant can move the Zen ball (red dot), the dot will “jump” to one or more screens.

- The basic mode involves dragging the Zen ball (red dot) along the base line within 25 seconds. The focus index is calculated and the ball is advanced to another screen based on that focus index. The exercises ends when the participant reaches the tenth screen; when this happens, a traditional low Buddhist chime sound is generated, acting as a reminder to the participant and to all in the area about mindfulness. Because posture, smooth movement, and careful attention are required to succeed in the basic mode of zen_Move, participants find that it heightens mindfulness.
- The mobile mode extends the basic mode so that a participant can practice the mindfulness exercise anywhere using a smart phone. The smart phone acts as a remote control displaying a single screen of the full installation at DDBC (which reacts in real-time) to the exercises being driven by the remote user. As observers see the Zen ball moving without any participant at the installation, they can infer that someone is performing the mindfulness exercise remotely. Fig. 3 shows a participant using the mobile mode.

ZEN_CIRCLE

zen_Circle is an interactive installation environment that uses wireless sensor networks to help guide participants as they engage in various types of walking meditation exercises on a large outdoor mandala fashioned in the shape of two embedded spirals. Fig. 4 shows this zen_Circle; the installation environment plays natural sounds and brahma music to give feedback to participants as they engage in walking

meditation. zen_Circle encourages participants to take time to walk and to integrate meditative practices actively in their everyday movements. zen_Circle is public art deployed in a circle shape design with audio feedback to guide participants.

zen_Circle permits several types of meditation known as walking meditation, and uses wireless sensor network technology to support interactive feedback. The zen_Circle interactive installation environment encourages participants to take time to walk and think (or meditate) in face of a busy life. We believe that this practice will encourage people to adjust the pace of their life, to relax in movement, and experience the benefits of this form of dynamic Zen.

WALKING MEDITATION

To understand zen_Circle, it is helpful to have a little background on walking meditation. While sitting meditation is perhaps the most respected form of Zen meditation, ordinary circumstances often make it difficult; and walking meditation is an alternative. The theory behind this type of meditation is that movement can help stimulate insights and a meditative state.

Two types of walking meditation are supported by zen_Circle. One type is *jingxing*. This type of meditation uses slow walking with specific posture suggestions.

A second type of walking meditation is *paoxiang* – this is a composite form of meditation that includes *jingxing*. Paoxiang, which literally means “walking incense,” is a group exercise – several monks, nuns, or lay people will walk in carefully coordinated sequence. Each participant must pay close attention to his or her movements at all times to avoid running into the person ahead, or creating a barrier for the person behind. Walking is divided into different phases – a slow walking phase (*jingxing*), a fast walking phase, and pausing phase. In classical technique, a meditation master guides the group by shouting out the different phases; in zen_Circle, signaling is given using sounds played on wireless sensor nodes attached to speakers.

SYSTEM AND INTERACTION SCENARIO

zen_Circle uses a double spiral laid out in the fashion of a large mandala (a traditional meditation tool associated with several forms of Buddhism and other Eastern religions) with five sensor nodes as shown in Fig. 4. In Buddhist thought, a mandala shows the cosmology of time and space. The zen_Circle interactive installation environment supports two modes. A simple switch in the control node shifts between basic *jingxing* and advanced *paoxiang* modes in the control node.

- *Jingxing* is the basic mode and supports a single participant. As the client sensor nodes detect that a participant is passing, they play sounds. The first sensor plays bird song, corresponding to the Buddhist “air” element. The second sensor plays the rustling sound of dry leaves, corresponding to the Buddhist “earth” element. The fourth sensor plays insect sounds, corresponding to the Buddhist “fire” element. The fifth sensor plays the sound of rushing water, corresponding to the Buddhist “water” element. The third sensor node has a special role, corresponding to the Buddhist “emptiness” element. The participant is directed to pause and meditate when he or she reaches the center. If the participant’s meditation lasts longer than ten seconds, all the nodes receive a signal from the control node, and all the nodes play synchronized brahma music for as long as the participant remains at the center of the installation.

Paoxiang is an advanced mode for participants who have extensive walking meditation experience. This mode is designed for multiple participants, who walk in synchronized fashion, focusing their mindfulness on their movements. To achieve synchronized movement (and avoid collisions) careful attention is required. In this mode, the first, second, fourth, and fifth nodes each play natural sounds for ten seconds when they are activated – if they are reactivated while the sound is playing they continue playing and reset their clocks to zero as they count to ten seconds. The characteristic *paoxiang* movements (rapid walking, *jingxing* slow walking, and pausing) are controlled by the third node, which generates the different control sounds randomly for random durations.

Paoxiang meditation in general, and particularly *paoxiang* in zen_Circle, teaches a form of unity of thought, since the actions of each participant reflect on the ability of the group to successfully complete the meditation exercise.

ZEN_SIT

zen_Sit is an interactive installation environment built in inside a room that includes extensive wireless sensor technology to monitor posture of participants through pressure sensors embedded in the meditation cushions used by the participants in sitting meditation. Fig. 5 shows zen_Sit. Information recorded by zen_Sit is displayed in a ceiling display that shows meditators with stable, even posture using a large circular rippling wave. The Zen master leading a sitting meditation session can thus immediately diagnose any meditators who lack good posture. All the status data are stored in sitting meditation database. Alternatively, the information can later be used to analyze various states in long meditation sessions.

SYSTEM AND INTERACTION SCENARIO

We use several pressure sensors embedded in the meditation cushion. We also integrated low-power wireless technology (Zigbee) to transmit pressure values from the cushion to the coordinator (a personal computer), forming a wireless sensor network. The coordinator processes input data from Zen meditation cushion and performs real-time statistical analysis on it to calculate a mindfulness index. The mindfulness index is visualized as a ripple flash animation projected on the ceiling. A more active ripple indicates a meditator for whom the pressure sensors indicate a deeper or more effective state of meditation. This allows the Zen master to easily monitor the status of the individual meditator participants. We also develop a database for zen_Sit to record each participant's Zen meditation level showed in Fig. 6. Through the interface of the Zen database, both teacher and participant can check the participant's practice history and meditation levels.

ZEN COMMUNITY

In addition to these interactive installation environments, we are currently building several others. There are more and more people immersed in our creative Zen learning space. The system gradually and naturally forms a meditation community. We have used our systems to collect a wide variety of data through our existing installations. Researchers at DDBC are interested in the possibility of collecting and using data to investigate physiological and behavioral aspects of meditation practices. While previous studies have been dealt with sitting meditation practices, less data is available for dynamic meditation, such as walking meditation. Since our data is collected by sensors in a natural fashion, in the course of

the ordinary operation of our interactive installation environments, it could be especially useful for study.

Zen is not a mystical religious activity but an efficient method of improving human physical and mental health. People can do Zen exercises easily in their daily life. Be inspired by the idea of carbon footprint from environmentalism, we propose the concept of “Zen footprint”: an index which describes the amount of Zen exercise to maintain peaceful minds. People who have a higher Zen footprint index are likely to have more peaceful minds. In *zen_Move* we will add up the total number of steps to calculate the Zen footprint. Similarly, in *jinxing* mode in *zen_Circle* we add up the total number of minutes that participants pause and think in the central node; in *paoxiang* mode, we collect the total number of the circles of the participants walking in the mode; in *zen_Sit*, we collect the total number of minutes that participants sitting with meditation practice.

In the future, we will integrate the smart phone system, the interactive installations and Google Map to build a Zen map to show the footprint in different places. Zen maps will offer real-time feedback that adds a geographic dimension to web e-learning systems.

CONCLUSION

This paper makes a number of novel contributions:

- It describes our creative interactive meditation space which is also an intelligent, invisible, informative and interactive space.
- It uses technology to motivate participants to engage in “ubiquitous Zen” where people can engage in walking meditation at any time in a wide variety of circumstances.
- It presents the conceptual design of these interactive installation environments, together with a discussion of how interactive multimedia can (somewhat paradoxically) engage participants in meditative and mindfulness practices.
- It includes a discussion of the actual building of these interactive installation environments. These environments are not merely conceptual designs or prototypes, but real, working systems that are actively used every day.
- It includes a discussion of the real-world engineering issues faced in supporting mobility and scalability in these interactive installation environments.

In contrast to many interactive multimedia systems, we have found that the environments comprising our creative interactive meditation space actually decrease distraction and help their participants relax and make achievements in mindfulness and relaxation. The installations also act to help suggest to participants that Zen practice is available at any time, any place. The *zen_Move* interactive installation environment is always available for one to pause and engage in a mindfulness exercise even through the smart phone interface. The *zen_Circle* interactive installation environment acts as a reminder that meditation can be integrated with one’s movements – even as part of one’s daily walks. The *zen_Sit* environment provides real-time feedback for sitting meditation allowing a Zen master to more effectively guide the meditator participants. We also hope to realize the concept of Ubiquitous Zen in a variety of cultural contexts and to support mind-brain cultivation.

EMBODIED SCHEMAS FOR CROSS-MODAL MAPPING IN THE DESIGN OF GESTURAL CONTROLLERS

Mark Linnane, Linda Doyle & Dermot Furlong

A conceptual framework for the design of intuitive gestural controllers for timbre manipulation from an Embodied Cognition perspective is proposed. This framework incorporates corporeal mimesis, affective/kinaesthetic dynamics, image schematic and conceptual metaphoric organization in order to speculate on possibilities in the design of mapping schemes between interface and synthesis algorithm.

Introduction

In contrast to traditional musical instruments, digital interfaces introduce an “arbitrary” component by encoding physical gesture as an electronic signal. This arbitrary component interrupts the natural, ‘felt’ sense of the interaction between performer and instrument and necessitates the introduction of control metaphors and mapping schemes that are not necessarily readily intelligible for non-technical users.

This paper focuses on the design of interfaces for the control of synthesized timbre. Several mapping strategies for control of synthesis have been proposed. However, it has been noted that empirical investigation of the “natural tendencies for multimodal mapping” is required in order to elaborate a generalizable set of cross-modal mappings. [1] We propose that the design of transparent, intuitive interfaces for timbre manipulation can be grounded in empirical analysis and subsequent artistic practice-based research focussed on cross-modal correlations between the user's embodied experience and a timbral perceptual domain. Gestural control is suggested as an appropriate paradigm in this context because it offers the possibility of affording intuitive control of sound via an intermediate ‘embodied’ mapping scheme based on ‘embodied’ characterizations of timbre and gesture.

Embodied Cognition offers a promising conceptual basis for this research. We suggest that structures common to cognition, multimodal perception and physical gesture can be identified. These correlations may then form the basis of a generalizable set of cross-modal mappings to be incorporated in the design of a gestural controller for timbral manipulation. This paper is a speculative outline of some possibilities for the application of embodied cognition in the design of gestural controllers for timbre manipulation.

Embodied Cognition

BACKGROUND

Embodied Cognition is an emerging research strand in a number of different disciplines that posits embodiment as profoundly constitutive of cognition. In general, Embodied Cognition analyses support the view of cognitive processes as creative, figurative acts structured by the teleological interactions of embodied agents with their environments and cultures rather than as largely passive processes of repre-

sentation and calculation. [2] A central claim of Embodied Cognition is that cognition and action are inextricably linked in lived experience. [3] Significantly, studies suggest that the specific structures of an organisms perceptual apparatus contribute to a structuring of all cognitive processes, not just those specifically recruited in perception.

Embodied Cognition analyses reveal a number of common primal structures and processes in cognition. These are learned via the common human experience of having a physical body and interacting in physical and cultural environments. Affective/kinaesthetic dynamics, Sensorimotor Mimesis, Image Schemata and Conceptual Blending have been identified for empirical analysis in this study. Essentially, the research question here is, for example, are Image Schemata activated by judgments of timbral quality and by gesture production and recognition? Can such schema be reliably demonstrated empirically? If so, what correlations exist, if any, between schema activated by timbre and those activated by gesture?

IMAGE SCHEMATA

Image schemata are basic features in cognitive processing acquired in early childhood development. They are based on basic dynamic embodied patterns and they give structure to more abstract conceptual processes. They are non-propositional, pre-conceptual structures that have a role in organising mental representations into coherent, meaningful units. They have a basic logic and are implicated in the formation of new concepts. Significantly for this study, they are focussed on perceptual interactions, and bodily and linguistic experience in social and historical contexts and they are inherently meaningful because of this embodied grounding. They are neurally encoded. [4]

The following are three simple examples of Image Schemata. The Link Schema is a simple physical or metaphorical structure whereby one object is linked to, and constrained by, another according to a basic symmetrical logic. Examples are the concept of a causal “connection”, or the physical act of connecting a laptop to its power source. The Container Schema has an Interior-Boundary-Exterior structure. It is based on the bodily experience of being a container and of being contained by something. The basic logic is that of the mutual exclusivity of interior and exterior and the necessity of being in one state or the other. The Source-Path-Goal Schema is based on bodily experiences such as throwing a ball. Other examples of Image Schemata as suggested by Johnson [5] are part-whole, centre-periphery, link, cycle, interaction, contact, pushing, balance, near-far, front-back and above-below.

An analysis of concepts of physical relation in the sentence, ‘The book is on the desk’ [3] illustrates the general form in which Image Schemata are implicated in the construction of meaning in linguistic expressions. Meaning here emerges by virtue of the fact that the Image Schemata activated by the linguistic expression are derived from a composite of neurally encoded embodied experiences such as being above, being in contact with, supporting, and so on. These experiences activate specific schemata which give meaning to the word ‘on’ in this expression. The experience of being ‘above’ yields an orientational schema; ‘contact’ yields a topological schema; and ‘support’, a force-dynamic schema. An important aspect of this process is that meaning does not arise through some kind of correlation between concept and objective ‘fact’, or by correlation of symbol and referent, but through a composite of activated schemata.

It is significant that several of these schemata have a structural identity with gestures or gestural components (e.g. source-path-goal schema, centre-periphery, above-below, pushing etc.). Johnson also presents analysis of image schemata across visual, kinesthetic and auditory modalities. [5] Image Schemata,

therefore, may offer a means of organizing gestural analysis in terms of the embodied structures of perception in other modalities.

CONCEPTUAL BLENDING

Lakoff and Johnson [6] argue that there are no literal definitions, only trans-domain mappings via metaphor. New concepts or categories are formed via the conceptual blending or mapping of a set of schemata from one domain to a target domain. For example, conceptual blending based on the Source-Path-Goal Schema yields complex causal patterns, such as that of ice changing state as it melts. Metaphorical conceptualization is, therefore, significantly constitutive of all thought. It is systematic, fundamental to language and thought and embodied. Such conceptual blends are implicated in cross-modal correlations such as judgments of timbre as being, for example, rounded, harsh, warm, heavy etc. It is important to note that gesture is fully characterizable within the framework of conceptual metaphoric mappings across modalities. [7]

SENSORIMOTOR MIMESIS

Sensorimotor Mimesis is any of several means by which humans imitate, consciously or unconsciously, covertly or overtly, an environmental or social stimulus. It is a crucial process in the psychological development of infants. It is often co-activated with other behaviors such as speaking, listening to music and working out logical problems. Mimesis is particularly significant because it appears to be implicated in cognitive tasks such as understanding and in affective responses to stimuli. In particular, vocal mimesis seems to be an important part of the music listening experience. People have the tendency to move in sympathy with music and, it appears, that this behavior is fundamentally constitutive of our understanding of, and affective response to music.

AFFECTIVE/KINAESTHETIC DYNAMICS

There is a formal congruency between motion and emotion. The felt quality of emotion is grounded in demonstrable dynamic patterns of physical expression. This is a reciprocal dynamic, emotions are shaped by motor attitudes, just as physical movement expresses emotion. Empirical studies by Bull [8] demonstrate the inability of subjects to experience particular emotions while adopting postural attitudes considered to be antithetical. Emotional expression is a kinetic phenomenon that has spatiality, temporality, intensity, and manner of execution. Phenomenological bracketing has been used to elucidate the dynamic structure underlying these forms. *Tensional* quality is mediated by the felt effort of postural attitude. *Linear* quality is directional contour of movement. *Amplitudinal* quality is the amount of extensiveness or constrictiveness of a posture. *Projectional* quality is the manner in which energy is released.

Sensorimotor Mimesis, considered along with Affective/Kinaesthetic Dynamics give us a theoretical framework within which analyse corporeal responses to stimuli. Mimetic responses to music are, seemingly, of a piece with our affective, aesthetic response. Affective/Kinaesthetic dynamics offer a structure whereby affective response can be assessed.

Hypothesis: Embodied Schemas for Gestural Manipulation of Timbre

In light of the above, we suggest that responses to timbre stimuli may be characterized as mediated by corporeal mimetic engagement according to affective/kinaesthetic dynamic structures. Timbres ‘feel’ a certain way due to this corporeal engagement. We further suggest that judgments of difference or similarity between timbres is mediated by an Image Schematic/Metaphoric structuring of differing corporeal attitudes. We suggest that such mapping processes mediate meaningful ‘navigation’ of timbre space via physical gesture. This view is supported by the observation that natural linguistic descriptions of timbre tend to emphasize embodied, cross-modal mappings through the use of multi-modal, embodied descriptors.

We suggest that empirical analysis may show that identical Image Schemata are activated by motor, visual and auditory stimulation. Substantial trends in cross-modal association have already been demonstrated. [9] We speculate that common cognitive structures may be shown to account for these correlations and to account for the tendency to describe sound in terms of weight, force, speed, intensity, emotion, spatial position and orientation, containedness, gravity, density, amplitude, colour, order, chaos etc. Essentially, we maintain that identical Image Schemata structure perception across modalities, thus allowing for perceptions of close correlation between certain gestures or shapes for example and certain timbres.

Such correlations would present a grounded basis for mapping schemes in gestural interfaces for sound synthesis. We propose that an empirical study of gesture performance and timbre perception that attempts to find the basis for cross-modal mappings between each is the first step in the design of these mappings for synthesis interfaces.

Design Approach

We propose empirical analysis and subsequent artistic practice-based research in order to elucidate cross-modal patterns. Study 1 will take the form of a preliminary subjective study designed to assess Image Schema activation in listeners in response to audio presentations of synthesized timbres and also, to assess the methodology with a view to later tests. The intent here is to assess the viability of a methodology which assumes that the perception of timbre difference is structured according to Image Schematic principles. Some of the following schema will form the test set; Path, Source-Path-Goal, Center-Periphery, Compulsion, Attraction, Link, Scale, Equilibrium, Full-Empty, Near-Far, Mass-Count, Iteration, Above/Below, Vertical Orientation, Length (extended trajectory), Rough-smooth/Bumpy-smooth.

Subjects will be presented with a set of synthesized timbres. These will be designed to include examples of pitched tones, percussive tones, instrument models and novel timbres. Each timbre example will be presented in pairs, once in an unmodified fashion then with one modification. Timbres will be modified in terms of some of the well-established factors known to be involved in timbre e.g. spectral envelope, harmonicity, spectral centroid, attack and decay envelopes.

A number of methods for assessing Image Schema activation are currently being considered. Subjects may be asked to supply linguistic descriptions of the presentations. The descriptions will be constrained to a limited set of options or to a defined metric and chosen in an onscreen interface. Subjects may also be asked to select the most appropriate graphical representation of an Image Schematic structure that describes the relationship between pairs of presented timbres. Synthesis will be implemented in

Max/MSP as will the user interface and response data collection system. Data will be subjected to statistical analysis in order to identify trends, if any, in subject response.

Study 2 will incorporate gesture capture via inertial sensors and a pair of sensor-enabled gloves. These sensors will enable the tracking of the relative position of the arms and the amount of contraction/expansion in the arms. Subjects will be asked to adopt whatever gesture or gestures they feel are appropriate responses to timbre stimuli as presented in the pilot study. Subjects will also be asked to perform gestures in response to linguistic and pictorial presentations of image schema as detailed above. This test will yield some measure of the corporeal mimetic response to timbre presentations in that it will provide some data on the Linear, Amplitudinal and Projectional qualities of the affective/kinaesthetic response. It will also establish whether it is plausible to assess schema activation in gesture production.

Study 3 will be a test of prototype mappings. If Tests 1 and 2 yield clear data, then there may be correlations between kinaesthetic and schematic activations in the case of both timbre and gesture that can form the basis of the design of systems in a phase of artistic practice-based tests focussing on art installation and music performance contexts.

Conclusion

Embodied Cognition is an area of cognitive science that focusses on perception, cognition and action as profoundly shaped by the human experience of having a body and living in a physical environment and in a culture. It suggests an alternative approach that complements current initiatives in the design of interactive technologies and gestural controllers. Embodied Cognition offers a novel way to analyse the complex interactions between user and technology in terms of the fundamental categories of embodied existence. These categories are involved in organizing perceptual phenomena into coherent, meaningful units and are implicated in the formation of new concepts. In turn, the design of meaningful controllers depends upon empirical knowledge of the fundamental categories whereby human beings interact with and understand their environment. In using these structures as a conceptual basis, it may be possible to identify correlations between gesture and phenomena, such as timbre, in other modalities. Such correlations are the necessary building blocks of a grounded cross-modal mapping schema on which to base the design of controllers that allow for meaningful gestural interaction with sound.

SECURE INSECURITY - PATTERNS OF TERROR

Robert B. Lisek

Is there a common structure of modern wars, which remains constant in the various wars? What is the relationship between terrorism, modern war and globalization? What is the order of war and terrorist attacks? There are common and predictable patterns to the way in which people are making a war, which go beyond the specific time and place.

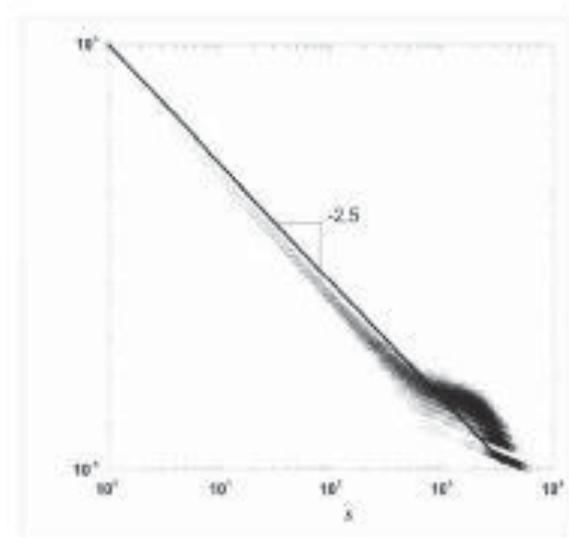

Fig 1. diagram of war, alpha=2,5"

$$P(x) = Cx^{-\alpha}$$

Diagram illustrating the pattern of war with annotations:

- number killed (points to x)
- slope of line (points to $-\alpha$)
- Probability of event (points to $P(x)$)
- constant (points to C)

Fig 2. pattern of war

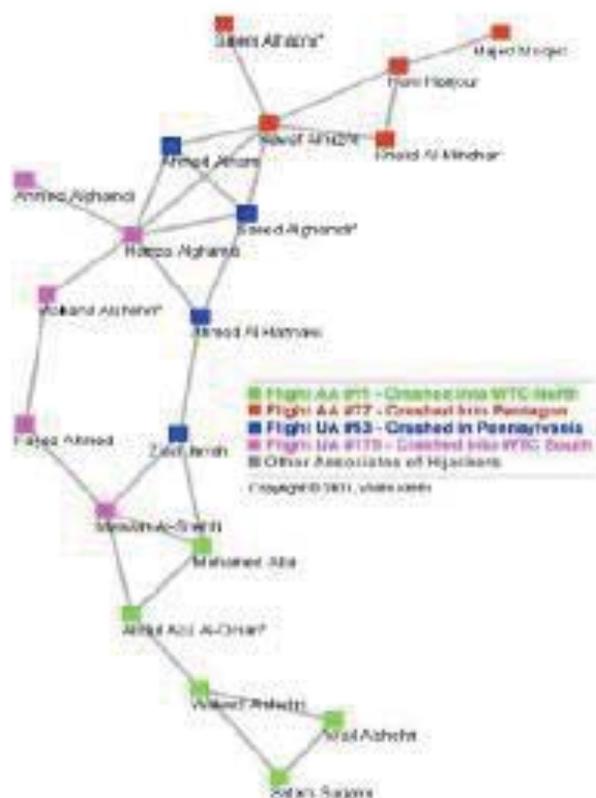

Fig 3. 9/11 terrorists network

There are common and predictable patterns to the way in which people are making a war, which go beyond the specific time and place. We find patterns in a variety of modern conflicts. These patterns are very similar to a distribution of victims of terrorist attacks. These patterns repeat itself constantly beyond differences in geography, ethnicity, religion and ideology.

What is a perfect terrorist cell? i.e. such cell whose structure is most difficult to destroy and disintegrate? How important is the security policy in the formation and development of modern terrorism?

Classically, it is assumed that terrorism is something from the outside, but a deeper study shows that it's something that the system does to itself. Contemporary terrorism is closely related to and generated by the security policy. From our point of view, the right approach is firstly to understand the nature of this global regulation. There's no terrorism coming from the outside. It's something that the system does to itself. Terror acts are seen as mutations and temporary deregulations of the system.

What is the relationship between security and the state? Security is a fundamental principle of the state and a main criterion of political legitimization. Security vs. discipline and law as instruments of governance. On one side, we have hard power structure based on discipline, differentiation and blockade, isolating power and closing the territories and on the second side: security policy associated with globalization, intervening and controlling processes, the security associated with liberalism because security may

only work in the context of transfer of persons and goods. The division proposed by Foucault and Agamben on the hard law and the dynamic activities of the security policy is an artificial assumption. These two areas are closely related, complementary and provide a medium for each other, e.g. processes related to the commodification of human life forcing changes in security policy or law acts, can be quickly changed by power elite. The increasing dynamism and complexity of social space and violent forms of bio-capital make this binary figure of thinking inadequate.

1. CHAOS OF INFORMATION AND OPEN INTELLIGENCE

We live in an accelerated transfer of data and chaos of information. In the media we see the news from Iraq, Afghanistan, Sierra Leone, or terrorist attacks but the conflicts appear to be very difficult to understand.

On the other hand we see how organizations like NSA suck millions of data about citizens from FB, twitter, etc. [open intelligence] by using the company Visible Technologies. Why not do the same? Apply similar methods and build your own software to analyze huge amounts of data for better understanding reality, war, conflicts and terrorism. Of course, you will not get such data from the Pentagon. So you need to find another way to obtain the data. These data are in streams of news that you eat. The whole noise around us actually has information. There are also open network database collecting data about terrorism. You can also use crawlers to obtain data from the Internet: publications of investigation journalists, bloggers, etc. If you can catch enough of these streams of information you can begin to understand terrorism and war.

2. THE SELECTION OF SOURCES. DATA SOURCES FOR TERRORIST EVENTS

The important thing is the selection and filtering of data. The first thing you should do is to collect data. Checking hundreds of different sources of information - from reports of NGO's to newspapers and cable news. Then, these raw data must be filtered. Next you extract key bits of information to build a database. This database contains times of attacks, location, size and type of weapon used.

It's all in the streams of information that we consume every day; you just must know how to select it. You can also use crawlers to obtain the data, see my project on Crash 2.0 concerning plane crash in Smolensk, where the Polish president was killed.

3. PATTERNS OF TERROR

When you have created the database you can search for patterns. What do we see for example when we look at the size distribution of attacks? What does it tell us? This can be done to get the following diagram for the sample data. On the horizontal axis, there is a number of people killed in the attack or the size of the attack and on the vertical axis you have a number of the attacks. This distribution was made for the war in Iraq. [4] It is a precise mathematical way of the distribution of attacks in this conflict and what happened here is quite surprising. The slope of the line is centred on the same values of Alpha, which is 2.5. Why is a conflict, such as the one in Iraq an invariant? Why is there an order in the war? Is it any special in Iraq? But when you look at a few more conflicts (Colombia, Afghanistan, Senegal) you can see the same pattern. These wars are different, with different religious groups, various political and various socio-economic problems but the underlying basic patterns are the same. (Figure01)

The similar pattern appeared, when I've made research for the terrorist attacks. The slope of the line is centred on the same values of Alpha, which is 2.5. We can also generate an equation that could predict likelihood of attacks. The probability of an attack killing X people is equal to a constant times the size of the attack, raised to the power minus Alpha where Alpha is the slope of the line on the diagram. (Figure 02)

Why these different conflicts and a series of terrorist attacks have the same patterns? One explanation is that the pattern describes general human behaviour: that insurgents are changing over time and adapt to the situation. If you do not behave in a certain way in the fight against much stronger opponents you will lose. Therefore, any insurgent force you choose, every conflict, which is in progress, it will look like on this diagram.

Alpha is a structure. It has a stable condition in 2.5. This is the image of war, when it is continued.

4. ABSOLUTE TERRORIST CELL

What is the absolute terrorist cell? What is the structure of indestructible terrorist cells? How to represent cells and how to study them?

Gordon Woo, a Catastrophe Consultant for the company Risk Management Solutions, has suggested modelling terrorist cells as graphs or networks - as collections of points or nodes connected by lines. [7] The nodes represent individual terrorists, and a line is drawn between two nodes if the two individuals have a direct communications link. In Krebs 2002, one finds graphs of the alleged September 11 hijackers. Of course a graph can represent any sort of social network, not just terrorists; for instance, your network of friends etc. [Figure03]. The task of law enforcement is to remove nodes from a graph representing a terrorist cell by capturing or killing members of that cell so that its organizational structure is disrupted. Woo suggests modelling this idea mathematically by asking the following question: How many nodes must you remove from the graph before it becomes disconnected (that is, before it separates into two or more pieces)?

However, modelling the terrorist cells as graphs ignores an important aspect of their structure, namely their hierarchy, and the fact that they are composed of leaders (decision makers, authors of attack plans, etc.) and of followers (couriers, soldiers, etc.). The structure is needed. A partially ordered set, or poset, is such a structure, and lattice theory is the branch of mathematics that deals with such structures. Below, we will delve into posets in greater detail, but first we give a brief overview. Our approach is based on the order theory. [6] A terrorist cell is a group of people, weapons, explosives, machines, or even information, which organizes itself to act as a single unit. The new model is that terrorist plans and decisions are formulated by the nodes at the top of the organization chart or poset (the leaders or maximal nodes); these plans and directives are transmitted down via the edges to the nodes at the bottom (the foot soldiers or minimal nodes), who presumably execute those plans.

Focusing on cutsets is trivial. [2] We do not merely want to break up terrorist networks into disconnected (non-communicating) parts. We also want to cut the leaders off from the followers. If we do that, then we can reasonably claim to have neutralized the network. A cutset is a collection of nodes that intersect every maximal chain. [Figure 05]

However, this approach does not take into account the fact that terrorist cells are continually transformed. So we need something more than posets, we need morphisms that serve as tools for transformation of posets. In other words, the problem is how to insert a dynamics into this static software world. You need to use morphisms. We can understand the dynamics of terrorist cells by using order preserving mappings, fixed points and retracts.

5. POLITICAL, SOCIAL AND PHILOSOPHICAL ASPECTS

What are the social causes and context of the emergence of terrorism?

The primary is feedback between the policy of security and terror. Security is a fundamental principle of state and main criterion of political legitimization. Security vs. discipline and law, as the instruments of governance. On one side we have hard power structure based on discipline, differentiation and blockade, isolating power and closing the territories and on the second side: security policy associated with globalization, intervening and controlling processes, the security associated with liberalism, because security may only work in the context of transfer of persons and goods. [1] The division proposed by Foucault and Agamben on the hard law and the dynamic activities of the security policy is an artificial assumption. These two areas are closely related, complementary and provide a medium for each other, e.g. processes related to the commodification of human life forcing changes in security policy or law acts, can be quickly changed by power elite. The increasing dynamism and complexity of social space and violent forms of bio-capital make this binary figure of thinking inadequate.

Disinformation and secrecy. The difference between the open and the secret implies a hierarchy, the first rule of power. On this difference, the structures called the state are being built. Limiting access to information leads to the emergence of different social classes. Security state is an engine of violence. Acts of terror and disaster are the lifeblood of political actions. That is why they are provoked and stimulated by the power elite. Security requires constant reference to the state of emergency. The quest for security leads to a global worldwide war. You have to change this way of thinking: reject the concept of security as a fundamental principle of state and test new models and constellations of power. The task of politics is to understand the conditions that lead to terror and destruction, rather than control these phenomena, as already occurred. Eternal swing between two extremes: security without freedom and freedom without security. The classic conflict between the ideals of security and freedom: two values that are necessary for a dignified and tolerable human condition, but extremely difficult to reconcile, takes on new forms.

Bio-exchange. The idea of "life" is considered to be included in the domain of technology, both for economic profits and for security reasons. Bio-economy. Biotechnologic artefacts, such as the database of the genome or the bio-chip are a special case of the configuration of knowledge production and bio-economy. These artefacts are a symptom of the commodification of life. The terrorist act is a knot in which a large number of social processes intersect. Meta-capital. Everything is partially interchangeable, as everything is connected. The relationship between the Capital and the Code becomes unsolvable. Is every code a capital? Is all the capital a code? Life becomes a currency of the genetic code. The code provided for trade, works as a social marker, as a new form of capital.

Another important cause of terrorism is an acceleration of flows and globalization. We live in societies where complexity and rate of flow of information, goods and people are constantly increasing by the

use of automation. It generates new social problems. Just as the increasing of metabolic functions of society such as the production and distribution have led to economic globalization, automation of information processing leads to the globalization of human cognitive abilities and decision-making mechanisms.

This results in a growing separation between the power (i.e.: the ability of doing things) and politics (i.e.: the possibility to decide which cases to settle). A few decades ago, they lasted seemingly inseparable connection, living in a state-nations construct. Now they live in the separate spaces: power in the space flows, politics in the space of places. Currently, the existing political institutions, invented in the course of two centuries of modern nations and states, are not relevant just as the tools of collective action for solving global problems like terrorism. Political action is not keeping up with the already globalized finance, industry, exploitation of natural resources, trade, migration of people and information, terrorism, trade of weapon and drugs.

The flow of people and building of ghettos. Not all individuals and groups have agreed to become a part of such a global system. Some individuals, nations or groups of countries do not want to be "integrated" in the transnational social superorganism.

The problem is mass migrations of people banished from homeland, people of "unnecessary" destitute. Ethnic, linguistic or religious diasporas in closed ghettos and crowded in close proximity. Selected districts in large cities serve as dustbins for the problems created by global powers.

Another problem is that this kind of technological progress increases the gap between the rich and the poor, and especially between those who have access to information and those who do not. The result is the emergence of a "subclass" of people excluded from the benefits of the flow. Today, the average income per capital richest country, Qatar, is 428 times greater than in the poorest country, Zimbabwe. [3] The richest fifth of the world appropriates 74% of the planet's annual income, while the poorest fifth has to settle for 2%. The first victim of growing division is democracy, where getting things for survival will become the main objective of the struggles and wars between different classes and groups.

TOWARD COMBINATORIAL COMPUTER SCIENCE

Robert B. Lisek

The primary goal of this article is to focus on the dynamics and processes of creation and transformation of organisms, structures and social organizations. A development of communication networks has caused research on systems that can function as 'neural system' for social organism. However, these earlier models remain on the level of metaphor. Our approach is more formal and uses mathematical tools.

The screenshot displays the vocento NEST web application. The top navigation bar includes 'My NEST' (Create, Upload, My Mail) and 'My Calendar' (Forum, Invite, Preferences). The main content area is divided into three sections:

- Left Panel:** A network graph showing nodes and connections. Nodes include 'Aubrey', 'Ben Alexander', 'Cassio Pennachin', 'AGRI', 'AGI conference', 'Immortality Institute', 'Aubrey David deGray', 'Bruce Klein', 'Xgalery', 'Mashe Looka', and 'Fundamental Research Art'. A search bar at the top left contains 'Aubrey' and 'Bob'.
- Center Panel:** A 'Rank Nodes' table with a 'Weight' dropdown menu. The table lists nodes with their ranks and labels:

Rank	Label
8	Ben Alexander
8	AGRI
4	Novemto LCD
4	Cassio Pennachin
3	Aubrey David d.
3	Immortality Instit.
3	Xgalery

NEST- ARCO Art Fair

1. Acceleration and 'global mind'

Connectivity, bandwidth and the size of resources grow. The increasing flow of information will create a true neural system of society in the future. Anarchy in the Internet proves its potential. The first step is to create a new Internet that learns new associations between data or concepts. Until now, a creation of links is done by hands, by authors of the documents, who determine what other documents are relevant to their text. This process is very inefficient. Search engines are still very archaic and could only partially alleviate this problem. We need 'thinking' Internet, which reinforces connections between documents

that are often used together and weakened between rarely used documents. 'Thinking' in means of using a dynamic network of connections for solving problems or responding to questions.

Based on AGI research and Internet extensions, progress will accelerate when a higher than human intelligence emerges. Large fast computer networks connected with human users can "wake up" as superhuman intelligent entities. We can create superhuman artificial intelligences in the next thirty years. Shortly after that, the era of human will end.

2. Portable knowledge development environment

If we want to create a real "neural system" of modern societies and transform the present society into the global mind, we need a good framework - portable knowledge development environment. We are looking for fundamental insight concerning human mind and its relation to the world, not only on a metaphorical level, but also as a strict formal framework. The main features of the framework:

Creativity: rapid construction, comparison and transformation of different structures with local rules and global behaviour

Flexibility: ability to support multiple tasks and representations

Soundness: Rooted in a solid mathematical basis. We use labelled, weighted, partially ordered sets (reflexive, transitive and antisymmetric) - propose them as base for a canonical framework for representation of knowledge and semantic information.

Self-reference: the structure must be able to relate to itself.

Inference and Data Mining: inferring new information from earlier data. Hyperset transformation and data mining methods (e.g. sequence analysis, network analysis, latent semantic analysis, and other statistical tools) to uncover hidden patterns and structural relations.

Diagram GUI: empirical tests as the way to find the appropriate mechanisms, guide this process by visual insight and graph manipulation.

The Development Framework would enable to build new structures, compare them in detail and then observe them in action. My general intention is to build systems, which have local rules, and then to observe their global behaviour. The environment would enable comparison of how changes in local systems will affect their global behaviour. I'm interested in gaining further insight into how to clarify the notion of transition from the local to the global, and how various elements come together and apart in the evolutionary dance.

As a result, we are interested in creating a software, which will be able to handle a great many different problems quicker and more effectively than man. Here, I'm presenting a conceptual framework for the development of a ,class' of intelligent systems. I emphasise on a ,class', rather than a single system. A system is intelligent not because of what it can do, but because of what it can learn to do. An intelligent system adapts itself to its environment and works with incomplete knowledge and resources. More precisely, the system has a set time and is always ready for new tasks, processing them in real time and learning from its own experience.

3. Retracts

We study systems in relation to their abstract properties, such as structure and organization. In our approach, it is essential to use the theory of ordered sets and fixed points of morphisms. In [1] we present state of knowledge in this field and the results based on new results related to retracts. We draw attention to the methods of representation, manipulation and measurement of partially ordered sets (reflexive, transitive, antisymmetric relations). Retracts and fixed points are central for the recursion and computability. Fixed points are important because they accurately characterize solutions of recursive definitions. It is convenient to describe the function using recursion, especially in programming languages. The problem is whether the functions are well defined. The idea is a method of successive approximations. The process of approximation provides fixed points, which are solutions of recursive equations.

Framework should be based on hyperposets - weighted labelled partially ordered sets. They allow the use of n -ary ordered relations represented as hyperedges – such edges that connect n nodes simultaneously. Hyperposets allow the building of hierarchies, ontologies and semantic networks. Posets are a subclass hyperposets. In hyperposets you can connect components in many different ways. Self-reference is possible, you can write an equation $f = f(f)$ with mathematical consistency.

A function $f : P \rightarrow P$ is order-preserving if, for all $p, q \in P$, $p \leq q$ implies $f(p) \leq f(q)$. A subset $Q \subseteq P$ is a retract if there exists an order-preserving map $f : P \rightarrow Q$ such that $f(q) = q$ for all $q \in Q$; the map f is a retraction. An element $p \in P$ is a fixed point of a function $f : P \rightarrow P$ if $p = f(p)$. The poset P has the fixed point property if every order-preserving map on P has a fixed point. A poset has the fixed point property if and only if every retract does .

4. Creation and transformation of organisms, structures and social groups.

4.1 We need formulas that explain how organisms mutate and propagate. Not only as in cellular automata or in genetic programming, but general and basic equations and new formalisms that allow self-reference, which is crucial for describing conscious systems. This means systems, that are able to "think themselves", to understand its limitations, create its own rules and modify their goals and methods. We also need simple equations to measure transformation and spreading. The key thing is to understand the evolution, the way in which new organisms are created and transformed. New structures are created by mutations and functions. For example, point mutations: remove an element (node) or insert a new element (or group of elements).

The most simple way of defining metrics in structure space is the number of point mutations required to transition from one organism to another, from one social organization to another. This is the general idea, but sometimes we need a more subtle way to define the distance of mutations, as $-\log_2$ probability that one organism is created from another by single mutation or retraction.

4.2 Self-production.

We refer to older tradition - cybernetics and systems theory. Although some old cybernetic models are based on central, hierarchical structure, new methods emphasize self-organization, autonomy, decentralization and interaction of many factors. Several models have been developed that can be used both for organisms and social systems: Miller (1978) - living systems theory, Maturana and Varela (1980, 1992) - theory of autopoiesis, Powers (1973, 1989) - perceptual control theory and Turchin (1977) - metasystem transition theory. In this approach, both social and biological organisms can be seen as special cases of more general category - "life" or "autopoietic system". Autopoietic (greek word for "self-production") system consists of a network of processes that recursively produce their own components and separate itself from environment. For example: living cells can be characterized as a complex network of chemical processes, which constantly mutate and produce molecules necessary for the functioning of cells. Reproduction is often seen as a function for defining "life". However copying without autopoiesis, which can be described more accurately as the replication, does not mean life: some crystals and viruses can replicate without life. We can talk about autopoiesis of societies where physical components of society can be described as its human members and their achievements (buildings, cars, roads, computers, books, etc.). Each of these components is produced by a combination of other elements from system.

4.3 The problem of the border. In the original definition of autopoiesis a fact is added, that the autopoietic system should produce its own borders or spatial or topological separation of system from the environment. In contrast to biological organisms, there is no clear boundary in social systems. For example, the state can produce most of its basic elements internally but it also needs to import some components (people, artefacts) and expertise from outside. This means that borders in social system are fuzzy.

4.4 Dynamics and spreading. Morphisms Processor

The most important is the transformation of structures. Morphisms are transformations of ordered sets. A topological structure of the network (weight of links and priority distribution) is changed through the use of morphism. We define a new concept: the energy of morphism. The energy of the morphism of an order set is a scale-invariant of morphism: function from morphism to rational numbers. The energy of set O is the infimum of energy of the set of all the morphisms of the order set of type O . The type and canonical form of an order set is based on a number of irreducible elements. Intuitively, the connection between the complexity of the morphism and its energy is simple: the more complicated morphism, the higher the energy.

These kinds of studies have many applications in creation of Artificial General Intelligence and finding solutions for problems associated with the emergence of complex, combinatorial objects and large data sets.

5. Automatic Programming

5.1 Automatic programming is a strong field from the very beginnings of the AI. PSI project at Stanford [2], which constructed a LISP, seems to be an important point of classical automatic programming. The automatic programming is "AI complete" in the sense that it requires general knowledge to understand what program/user wants to achieve (without determining details in a programming language). Artificial General Intelligence (AGI) is connected with 'unlimited' ability to learn. Framework must be experimental, cognitive architecture, which learns by modifying and extending itself, including developing an ability to learn (better learning). Let's assume that learning is treated as programming: learning is designing a new algorithm. Learning as an ability to write programs. Learning as a general knowledge of the world is

to build a model that is able to predict the consequences of events or activities. In this perspective, general program learner is a program that writes programs. It is a program that has to invent both the algorithms and representations. Such programs can easily operate on each other and produce other programs, much in the way that molecules can react and produce other molecules. For human programmers, the programs become more complex, it makes sense to develop new languages in order. This regularity also holds for AI systems. Unlimited learning system will be a system that invents new programming languages.

5.3 Architecture and machines based on partially ordered sets

LISP introduced abstract syntax tree (AST) as a base type of data and automatic memory management method. It was also probably the first functional programming language. PLANER, PROLOG and a variety of systems have introduced automated theorem proving, now widely used in most modern languages. The objects oriented semantics of many modern languages, derives from the architecture of systems from the 70s'. Currently, we need to create a new class of languages in which a base type of data will be partially ordered set. Ordered sets are richer structures than chains and trees used in all languages and computing machines that we know. At the same time posets are structures that we can strictly control. Therefore, building a new architecture and computers based on posets would be an important step towards the implementation of AGI and global mind idea.

AVATAR MANIFESTO REDUX

Gregory Little

In this presentation, “*Avatar Manifesto Redux*”, I will bring specific trajectories of the 1999 essay “*An Avatar Manifesto*” to bear on some examples of the current state of avatar research and construction.

“The truth was that he was entirely dissatisfied with the image of his own face, yet the river, continuously changing under the continuously changing light, and promising so much to Narcissus, nurtured an inexhaustible hope in him, and hopes: the hope that he would be satisfied, and beautiful enough, as an image, a face and a being, to be able to be loved by a truly beautiful being.

But the river itself was the most beautiful of all the beings he had ever beheld.” [1]

_Delmore Schwartz, Last and Lost Poems

In 1989, after taking a test drive in “Reality Built for Two”, a virtual reality simulator built by Jaron Lanier and VPL Research, I began to speculate upon how we might appear to one another in Multi-user Virtual Environments (MUEs). The potential for choosing non-consensual, mutable, or hybrid self-representations led me to create a series of images called 'identity constructions', to design prototypes of identity creation interfaces, and to write speculative theory about the ramifications of this process. The decade hosted the emergence of the World Wide Web and Virtual Reality Modeling Language (VRML). Online spaces like *AlphaWorld™*, *WorldChat™*, and *WorldsAway™* combined MUDs with 3d virtual worlds. The popularity of Neil Stephenson's novel *Snow Crash* brought the term avatar into public acceptance, and a plethora of cinematic efforts beginning with Disney's *Tron* (1982) including *Lawnmower Man*, *Brainstorm*, *Until the End of the World* and the television mini-series *Wild Palms* warned us of the dangers of our inevitable virtual futures. These fictions lost their momentum as the web increasingly became a space for the exchange of goods and services, for surveillance and mapping of consumption. As our enthusiasm and patience for MUEs and real-time 3D peaked mid decade, it became clear to me that the most significant property of the avatar was the freeing of personal identity from mapable relationships to consistency and social consensus. I wrote that the use of the avatar in on-line shared environments had the potential to become a revolutionary polymorphic trope as the human driver could choose to be unhampered by issues of class, race, gender, beauty, or age in how they represented themselves in MUEs. The avatar could become a potential site of resistance, a trickster figure, a viral glitch in the flow of online commerce.

In 1999 I published “*An Avatar Manifesto*”, an essay that posited a historical and theoretical definition of the avatar, contextualized the avatar among other types of representation, and articulated a set of poetic strategies for building avatars intended to resist the inevitable construction of virtual space as a new utopian shopping mall. The essay referenced Donna Haraway's “*Cyborg Manifesto*” of 1986 and used Artaud's trope, 'The Body w/o Organs' as a point of reference for the construction and articulation of representations of the self within digital, virtual space. In the current essay, “*Avatar Manifesto Redux*” I will revisit the definition of the avatar, and bring specific trajectories of the the avatar to bear on current state of avatar research and construction. I find at least four recurring variants on the avatar to be of interest: the profile, the portrait, the tool, and the double.

WHAT IS AN AVATAR?

Avatars are online, virtual constructions that both represent and act as a tool for a user in shared virtual spaces. As is widely understood, the origins of the term lie in Hindu philosophy: AVATARA-Sanskrit.; ava-'down', tarati-'he goes, passes beyond' literally, 'a descent', a conception described in the *Bhagavad gita*, 4th Teaching, 1-8 where Krishna confides: "when goodness grows weak, when evil increases, I make myself a body," [2] or, an alternative translation: "Whenever righteousness wanes and unrighteousness increases I send myself forth." The use of the term avatar to represent the self or user in the context of shared on-line Internet environments first occurs in the early 1980's with the development of LucasFilms's *Habitat* project and later came to popular consciousness with the success of the novel *Snow Crash*, where avatars are the digital representations of the inhabitants of the 'MetaVerse'. The past two decades have been marked by our pre-occupation with 'sending ourselves forth' into parallel worlds of signification.

THE PROFILE:

Today the most prevalent on-line representation of the self is the user profile, as found on social networking sites like: *LinkedIn*, *Friendster*, *MySpace*, *Twitter*, *Google Profile*, *Badoo*, *Bebo*, *Jaiku*, and *Facebook™*. User profiles are often information dense and provide tremendous involvement on the users part for tweaking and refining.

As Christine Rosen states in "Virtual Friendship and the New Narcissism," users of social networking sites are committed to self-exposure. The impulse to collect as many 'friends' as possible on a social networking page is as much an expression of the need for status as it is the need for friendship.

"The creation and conspicuous consumption of intimate details and images of one's own and others' lives is the main activity in the online social networking world." [3]

This constant self-monitoring and profile tweaking can be understood as classic Narcissism playing out on a massive social scale. Sherry Turkle has posited in "Always-on/Always-on-you" that our current, personally/personality-presentation technologies, especially social networks and smart phones, take self-monitoring to a new level. "We try to keep up with our lives as they are presented to us by a new disciplining technology, our new "relational artifacts." [4] As most of us spend a great deal of time constructing, monitoring, updating, and editing our various profiles, it seems that the purpose of the profile is, following Turkle's logic, to literally make the self into a relational artifact; to expose the self in all its monotonous uniqueness, of conventional individuality, of distinctive sameness, and to make the self available for monitoring by others. Earlier examples of this level of self-exposure include Jennifer Ringle's lifecast "JenniCam" (1996-2003), and Eva and Franco Mattes "Life Sharing" (2000) where the artists turn their personal computers into open source servers. Profile browsing is another form of monitoring and "data mining", a one-way action and voluntary voyeurism as we passively scan another's personal archive without their lived presence or knowledge. *Facebook™* is largely not face to face, our profiles are not temporal or spatially co-present with the profile of the other.

Indeed, our profiles are the organizing principle of these sites. Our profiles are mined not only by other users by the sites themselves, forming what Edward Castronova has called the "coding authority." [5] The coding authority uses the data from this mining to construct psycho-geographic 'spaces.' In the process the sites shift from organization via metaphors of place, to organization of and navigation

through anthropomorphized data spaces structured around personality attributes: for example, likes, interests, preferences, histories, comments, friends, occupations, or avocations. Such geographies are frequently rooted in constructions that are non-consensual and often deracinated. This data-mining by the coding authority in endogenic, and non-ludic spaces like *Facebook™* contributes to a redefinition of the function of community, of portrait, and avatar. Each becomes a relational artifact, a tool for self-monitoring, a personal panopticon. As we gaze into our screens, shaping our protean selves; the river gazes back and records our every gesture.

THE TOOL:

Edward Castronova, in his “Theory of the Avatar” posits that we, or more precisely, our minds 'drive' our avatar representations in a variety of spaces, both real and virtual.

“When visiting a virtual world, one treats the avatar in that world like a vehicle of the self, a car that your mind is driving.” [6]

Castronova posits that the avatar is essentially a body that represents a mind; that the body can be real or virtual...in other words, we always occupy an avatar, whether in real life on earth, or *Second Life™*, whether a flesh and blood body or a body of pixels and light. For Castronova the driver of the avatar is the mind, the earthly body is not the seat of the mind, of sensation, breath, of life itself; but merely an avatar we can choose not to inhabit, a tool in our toolbox. Castronova writes that we make our choice of tool dependent upon what we want to accomplish in a particular world, and that we make this choice according to three vectors: x is the fixed non-physical characteristics of the agent, v is the changeable avatar attributes, and z is the changeable world attributes. Our choice is dependent upon economy and utility, on which tool or representation will work best in the chosen world according to the perimeters of the vectors xvz as defined above. The ramifications of this definition are useful and insightful, but I must disagree with his definition of the avatar. Such an idealist view of the nature of mind is useful to Castronova's theory. We can all imagine Matrix-like futures where all sensation is virtualized; the corporeal body hangs in a closet, and the brain is in a jar. This view is not tenable. Rather, I support a materialist view of the relationship between mind and body which holds that the mind is a largely physical entity and that mental states are largely derivative of physical ones. Regardless of whether we are in SL or RL the corporeal body is required to sense and process either world. We use our sense organs whether located or co-located. Despite of our level of immersion in a virtual world we are constantly “poked” by the physical expressions of the real world, of biological processes and of needs of our bodies. Although the “driver” and “vehicle” relationship is a useful description, which draws from the prefix 'cyber' (as in cybernetics), meaning 'to steer', the avatar is not the automobile. The avatar is a highly unique form because it involves an ontological pairing, a contradictory hybridity. The avatar is both the driver and the driven, the lived representation composed both of flesh and light, an 'I' that makes a body. The avatar is a 'viractual' object; the contradiction between the virtual and the real is merged at the avatar's core. Castronova weaves an argument that the proper choice of the avatar can, and I agree, have utility and initiate positive change in our lived experience. I must simply add to vector x (the fixed non-physical characteristics of the agent) that the fixed physical characteristics of the agent mold the equation. The translation of live body and lived experience into a simple rasterized image is too lossy a translation to be useful. Liveness, the temporal co-presence of the lived body transmitting data and the simultaneous expression of that data as virtual representation (where duration is the same for the real and the virtual) is a definitive property of the avatar. The avatar joins the a computed representation with the presence of a lived body transmitting data, right now.

PORTRAIT:

The 38,100,000 hits returned when googling 'avatar portrait' is testimony to the ubiquity of the association of avatars with portraits (and the popularity of Cameron's *Avatar*). The internet is filled with avatar portrait generators, galleries of avatar portraits, services to create custom avatar portraits, artists willing to paint canvases of your avatar, even those claiming the ability to represent the aura of your avatar. As I wrote in 1999:

“the population of avatars could come to include the history of portraiture in painting, photography, and sculpture, as a projection or passing through of once living individuals into the virtual, timeless space of representation, metaphor, and mimesis.” [7]

In “Life and Its Double,” [8] (2007) the art critic and curator Domenico Quaranta, while discussing the work of Eva and Franco Mattes, writes of the status of the avatar as a portrait, and seeks to define avatar portraits as a new genre within the canon of Art History. Indeed it is a very appealing construct as I also believe that the avatar is a new, definitively unique genre of portraiture. However I cannot fully endorse Quaranta's construction of its significance or meaning as outlined in his essay “Life and its Double.” A distinction must be made between the portrait of an avatar, which is not in and of itself an avatar; and the avatar defined as a portrait. Quaranta outlines multiple arguments for the avatar as a new genre of portraiture while discussing portraits of avatars. Avatar as portrait is in my estimation a far more interesting candidate for a new genre in Art History than portraits of avatars. As I shall argue, avatars expand and redefine our notions of image, representation, liveness, self, and identity.

The collapsing of the definitions of avatar and portrait is useful to characterize the avatar in extant art historical classifications, but the insistence that the Mattes portraits of the avatars exhibited in-world in “Ars Virtua” are of the “same substance as their subjects” [9] is in my view incorrect. As argued above, the avatar is more than “in-world” pixels or image, the avatar is both “in” and “out of world”, it is driven in real-time by a corporeal person in a real, single location. Philip Rosedale, the creator of *Second Life™*, places emphasis on embodiment when he defines avatar as “the representation of your chosen embodied appearance to other people in a virtual world.” [10]

To use Castronova's description, the Mattes' portraits of avatars are no longer being driven, they are now parked or abandoned avatars. Although like avatars they are representations of agents or users, they must not be confused with avatars, they are now portraits in the traditional sense, and like all such representations disconnected in time and space from their referents, the real-world human acting in real-time from a specific single location.

Each of the ideas about avatars that I address above deny, compromise, or underplay the existence of the real-time user as a condition of the avatar. As noted above, Joseph Nechvatal writes that the paradoxical condition of a viractual object fuses the computed representation and the uncomputed corporeal, therefore to define the avatar as a viractual object “tends to contradict some central techno cliches of our time.” [11] It is the condition of duality in the avatar, the parenting of the representation of the self to a real-life user in real-time that defines the avatar's unique ontology and distinguishes it from other forms of representation.

The avatar has proven to be a far more unique construct than I realized when I wrote “A Manifesto for Avatars” twelve years ago. Unlike most forms in telematic culture, e.g. the profile, the avatar does not

lack a Benjaminian 'aura' The driven avatar is not lacking in “its presence in time and space, its unique existence in a place where it happens to be,” that is to say, it has what Benjamin called “authenticity,” or, an “aura.” Because the nature of an avatar is viractual; its methodology is essentially performative, involving the real-time transmission, through image, text, and gesture, of the simultaneous lived experience of its driver/user/agent. Any attempt to archive an avatar must include not only a library of visual representations, but a dataset of gestures, sounds, texts, and algorithms as well as information about the corporeal uncomputed body. Data-mining by the coding authority could provide this archive, and it should be open-source. When one encounters another avatar in a MUVE space like *Second Life™*, we must do so with a full knowledge that, like a psychological double, we are being presented with an uncanny condition that is both familiar and unknown, both revealing and hidden. There is a lived but hidden presence behind the avatar's back, ontologically and spatially separate but temporally and intentionally bound. This corporeal force, like the beloved river for Narcissus, is the origin of signification. Like the psychological or literary double the origin of the expressive power of the avatar lies in paradox and in fusing of opposites, in the condition Freud called the 'uncanny.' For Freud the uncanny was a province of aesthetics.

I find at least four recurring variants on the avatar to be of interest: the profile, the portrait, the tool, and the double.

WHAT IS AN AVATAR?

Avatars are online, virtual constructions that both represent and act as a tool for a user in shared virtual spaces. As is widely understood, the origins of the term lie in Hindu philosophy: AVATARA-Sanskrit.; ava-'down', tarati-'he goes, passes beyond' literally, 'a descent', a conception described in the *Bhagavad gita*, 4th Teaching, 1-8 where Krishna confides: "when goodness grows weak, when evil increases, I make myself a body," [2] or, an alternative translation: "Whenever righteousness wanes and unrighteousness increases I send myself forth." The use of the term avatar to represent the self or user in the context of shared on-line Internet environments first occurs in the early 1980's with the development of LucasFilms's *Habitat* project and later came to popular consciousness with the success of the novel *Snow*

Crash, where avatars are the digital representations of the inhabitants of the 'MetaVerse'. The past two decades have been marked by our pre-occupation with 'sending ourselves forth' into parallel worlds of signification.

THE PROFILE:

Today the most prevalent on-line representation of the self is the user profile, as found on social networking sites like: *LinkedIn*, *Friendster*, *MySpace*, *Twitter*, *Google Profile*, *Badoo*, *Bebo*, *Jaiku*, and *Facebook™*. User profiles are often information dense and provide tremendous involvement on the users part for tweaking and refining.

As Christine Rosen states in "Virtual Friendship and the New Narcissism," users of social networking sites are committed to self-exposure. The impulse to collect as many 'friends' as possible on a social networking page is as much an expression of the need for status as it is the need for friendship.

"The creation and conspicuous consumption of intimate details and images of one's own and others' lives is the main activity in the online social networking world." [3]

This constant self-monitoring and profile tweaking can be understood as classic Narcissism playing out on a massive social scale. Sherry Turkle has posited in "Always-on/Always-on-you" that our current, personally/personality-presentation technologies, especially social networks and smart phones, take self-monitoring to a new level. "We try to keep up with our lives as they are presented to us by a new disciplining technology, our new "relational artifacts." [4] As most of us spend a great deal of time constructing, monitoring, updating, and editing our various profiles, it seems that the purpose of the profile is, following Turkle's logic, to literally make the self into a relational artifact; to expose the self in all its monotonous uniqueness, of conventional individuality, of distinctive sameness, and to make the self available for monitoring by others. Earlier examples of this level of self-exposure include Jennifer Ringley's lifecast "JenniCam" (1996-2003), and Eva and Franco Mattes "Life Sharing" (2000) where the artists turn their personal computers into open source servers. Profile browsing is another form of monitoring and "data mining", a one-way action and voluntary voyeurism as we passively scan another's personal archive without their lived presence or knowledge. *Facebook™* is largely not face to face, our profiles are not temporal or spatially co-present with the profile of the other.

Indeed, our profiles are the organizing principle of these sites. Our profiles are mined not only by other users by the sites themselves, forming what Edward Castronova has called the "coding authority." [5] The coding authority uses the data from this mining to construct psycho-geographic 'spaces.' In the process the sites shift from organization via metaphors of place, to organization of and navigation through anthropomorphized data spaces structured around personality attributes: for example, likes, interests, preferences, histories, comments, friends, occupations, or avocations. Such geographies are frequently rooted in constructions that are non-consensual and often deracinated. This data-mining by the coding authority in endogenic, and non-ludic spaces like *Facebook™* contributes to a redefinition of the function of community, of portrait, and avatar. Each becomes a relational artifact, a tool for self-monitoring, a personal panopticon. As we gaze into our screens, shaping our protean selves; the river gazes back and records our every gesture.

THE TOOL:

Edward Castronova, in his “Theory of the Avatar” posits that we, or more precisely, our minds 'drive' our avatar representations in a variety of spaces, both real and virtual.

“When visiting a virtual world, one treats the avatar in that world like a vehicle of the self, a car that your mind is driving.” [6]

Castronova posits that the avatar is essentially a body that represents a mind; that the body can be real or virtual...in other words, we always occupy an avatar, whether in real life on earth, or *Second Life™*, whether a flesh and blood body or a body of pixels and light. For Castronova the driver of the avatar is the mind, the earthly body is not the seat of the mind, of sensation, breath, of life itself; but merely an avatar we can choose not to inhabit, a tool in our toolbox. Castronova writes that we make our choice of tool dependent upon what we want to accomplish in a particular world, and that we make this choice according to three vectors: x is the fixed non-physical characteristics of the agent, v is the changeable avatar attributes, and z is the changeable world attributes. Our choice is dependent upon economy and utility, on which tool or representation will work best in the chosen world according to the perimeters of the vectors xvz as defined above. The ramifications of this definition are useful and insightful, but I must disagree with his definition of the avatar. Such an idealist view of the nature of mind is useful to Castronova's theory. We can all imagine Matrix-like futures where all sensation is virtualized; the corporeal body hangs in a closet, and the brain is in a jar. This view is not tenable. Rather, I support a materialist view of the relationship between mind and body which holds that the mind is a largely physical entity and that mental states are largely derivative of physical ones. Regardless of whether we are in SL or RL the corporeal body is required to sense and process either world. We use our sense organs whether located or co-located. Despite of our level of immersion in a virtual world we are constantly “poked” by the physical expressions of the real world, of biological processes and of needs of our bodies. Although the “driver” and “vehicle” relationship is a useful description, which draws from the prefix 'cyber' (as in cybernetics), meaning 'to steer', the avatar is not the automobile. The avatar is a highly unique form because it involves an ontological pairing, a contradictory hybridity. The avatar is both the driver and the driven, the lived representation composed both of flesh and light, an 'I' that makes a body. The avatar is a 'viractual' object; the contradiction between the virtual and the real is merged at the avatar's core. Castronova weaves an argument that the proper choice of the avatar can, and I agree, have utility and initiate positive change in our lived experience. I must simply add to vector x (the fixed non-physical characteristics of the agent) that the fixed physical characteristics of the agent mold the equation. The translation of live body and lived experience into a simple rasterized image is too lossy a translation to be useful. Liveness, the temporal co-presence of the lived body transmitting data and the simultaneous expression of that data as virtual representation (where duration is the same for the real and the virtual) is a definitive property of the avatar. The avatar joins the a computed representation with the presence of a lived body transmitting data, right now.

PORTRAIT:

The 38,100,000 hits returned when googling 'avatar portrait' is testimony to the ubiquity of the association of avatars with portraits (and the popularity of Cameron's *Avatar*). The internet is filled with avatar portrait generators, galleries of avatar portraits, services to create custom avatar portraits, artists willing to paint canvases of your avatar, even those claiming the ability to represent the aura of your avatar. As I wrote in 1999:

“the population of avatars could come to include the history of portraiture in painting, photography, and sculpture, as a projection or passing through of once living individuals into the virtual, timeless space of representation, metaphor, and mimesis.” [7]

In “Life and Its Double,” [8] (2007) the art critic and curator Domenico Quaranta, while discussing the work of Eva and Franco Mattes, writes of the status of the avatar as a portrait, and seeks to define avatar portraits as a new genre within the canon of Art History. Indeed it is a very appealing construct as I also believe that the avatar is a new, definitively unique genre of portraiture. However I cannot fully endorse Quaranta's construction of its significance or meaning as outlined in his essay “Life and its Double.” A distinction must be made between the portrait of an avatar, which is not in and of itself an avatar; and the avatar defined as a portrait. Quaranta outlines multiple arguments for the avatar as a new genre of portraiture while discussing portraits of avatars. Avatar as portrait is in my estimation a far more interesting candidate for a new genre in Art History than portraits of avatars. As I shall argue, avatars expand and redefine our notions of image, representation, liveness, self, and identity.

The collapsing of the definitions of avatar and portrait is useful to characterize the avatar in extant art historical classifications, but the insistence that the Mattes portraits of the avatars exhibited in-world in “Ars Virtua” are of the “same substance as their subjects” [9] is in my view incorrect. As argued above, the avatar is more than “in-world” pixels or image, the avatar is both “in” and “out of world”, it is driven in real-time by a corporeal person in a real, single location. Philip Rosedale, the creator of *Second Life™*, places emphasis on embodiment when he defines avatar as “the representation of your chosen embodied appearance to other people in a virtual world.” [10]

To use Castronova's description, the Mattes' portraits of avatars are no longer being driven, they are now parked or abandoned avatars. Although like avatars they are representations of agents or users, they must not be confused with avatars, they are now portraits in the traditional sense, and like all such representations disconnected in time and space from their referents, the real-world human acting in real-time from a specific single location.

Each of the ideas about avatars that I address above deny, compromise, or underplay the existence of the real-time user as a condition of the avatar. As noted above, Joseph Nechvatal writes that the paradoxical condition of a viractual object fuses the computed representation and the uncomputed corporeal, therefore to define the avatar as a viractual object “tends to contradict some central techno cliches of our time.” [11] It is the condition of duality in the avatar, the parenting of the representation of the self to a real-life user in real-time that defines the avatar's unique ontology and distinguishes it from other forms of representation.

The avatar has proven to be a far more unique construct than I realized when I wrote “A Manifesto for Avatars” twelve years ago. Unlike most forms in telematic culture, e.g. the profile, the avatar does not lack a Benjaminian 'aura' The driven avatar is not lacking in “its presence in time and space, its unique existence in a place where it happens to be,” that is to say, it has what Benjamin called “authenticity,” or, an “aura.” Because the nature of an avatar is viractual; its methodology is essentially performative, involving the real-time transmission, through image, text, and gesture, of the simultaneous lived experience of its driver/user/agent. Any attempt to archive an avatar must include not only a library of visual representations, but a dataset of gestures, sounds, texts, and algorithms as well as information about the corporeal uncomputed body. Data-mining by the coding authority could provide this archive, and it should be open-source. When one encounters another avatar in a MUVE space like *Second Life™*, we

must do so with a full knowledge that, like a psychological double, we are being presented with an uncanny condition that is both familiar and unknown, both revealing and hidden. There is a lived but hidden presence behind the avatar's back, ontologically and spatially separate but temporally and intentionally bound. This corporeal force, like the beloved river for Narcissus, is the origin of signification. Like the psychological or literary double the origin of the expressive power of the avatar lies in paradox and in fusing of opposites, in the condition Freud called the 'uncanny.' For Freud the uncanny was a province of aesthetics.

HACKERSPACES: FROM ELECTRICAL TO CULTURAL RESISTANCE

Ricardo Lobo

Hackerspaces are community-driven spaces where people gather to socialize, experiment, learn and develop projects with technology. Over the past four years, these spaces have seen a remarkable growth in number and visibility. In this paper, we examine how the practice of hackerspaces can be understood as a form of cultural resistance by analyzing some views and attitudes towards the economy, education, society and politics.

Introduction

The purpose of this paper is to contribute to the study of this global movement of spaces and communities around the globe where people create and experiment with technology, known as hackerspaces. It is a phenomenon that in recent years has shown a considerable expansion. Despite that fact, hackerspaces are still largely underresearched.

Our research interest grew out of the field work we've been doing in Audiência Zero. Audiência Zero is a Portuguese cultural organization responsible for a network of spaces of creation and experimentation with technology that in recent years has re-defined itself largely under the influence of the hackerspace model. Our ultimate interest is to investigate the actual and potential impacts of the hackerspace movement in the social, political, economic and cultural spheres.

Mitch Altman, founder of NoiseBridge, once said, in passing, that the future of everything is on the hackerspace. A highly colored statement of course, but the idea that the hackerspace is an innovative and dynamic concept with much to offer to society at large is something that we believe deserves attention.

Hackerspaces are local communities who share a global culture, and are a direct descendant of the hacker culture. Hackers manifest their culture through very specific practices and values. This hackerspace culture is in many ways, as we shall see, contrary to the cultural discourse of dominant political, social and economic structures.

Nevertheless, hackerspaces are not closed organizations, they are in permanent contact with society, always interested in showing what they do and explain why they do it. This form of relationship with the outside world, makes hackerspaces values and practices publicly known. This, in turn, might influence the way other people see, think and behave. This form of cultural resistance is what we are going to address in this paper.

What is a Hackerspace?

Hackers are the first to point out that there aren't two hackerspaces alike (Schneeweisz 2009). The main reason for this has to do with the fact that hackerspaces are the direct product of the communities that

created them. Regular discussions about the definition of hackerspace have occurred in the community, but there isn't an agreed, compact definition of hackerspace so far (Moilanen 2010).

Nonetheless, we will provide a tentative definition of hackerspace, that we believe will suffice for the purpose of this paper. We will then elaborate a little on the definition in order to adequately explain the main elements.

For us a hackerspace is an open, community-driven space with shared resources, where people with common interests, learn, experiment and develop projects, through an organizational model based on peer-learning, collaboration and knowledge sharing.

A hackerspace needs a physical space for members to meet and work. Here is where the resources are located, where the activities take place. Usually these spaces are rented. The rent and all the operational costs are paid by members fees. Ideally members will have 24/7 access to the space which means that each member has to have a key.

Around the space a community settles and grows. The community is responsible for financing and managing the space and the resources, usually through elected bodies. This community is, in many cases, open, by which we mean: receptive to new members, organize activities in which non-members can participate and build ties with outside people and organizations.

The people who create the community around a hackerspace have common interests, that's why they gather, cooperate and maintain a hackerspace. The interests of these hackers can be quite varied, but fairly typical is the interest in technology, science and art.

Those interests determine the resources available in hackerspaces, but other factors are important too, like money and available space. Examples of shared resources that are commonly found in hackerspaces are: Internet access, electronic equipment, workshop tools and prototyping machines (3D printer, CNC).

The community exists because its members share resources and common interests which usually materialize in experiments and projects, this means hackerspaces are spaces of experimentation and development, not just socialization.

In the community there is a rooted practice of information sharing and collaboration. Members with different levels of knowledge and different backgrounds are available and willing to share what they know with others. This is one of the biggest selling points of hackerspaces, a community of people from various fields, with very good skills and available to help whenever necessary.

So these elements are very relevant to the definition of a hackerspace: space, community, common interests, resources, collaboration, creating, experimenting and sharing. Some of these elements relate to physical resources; other to the activities that occur there; and finally, to the values and practices embodied. This multidimensional reality is one of the reasons that make defining a hackerspace a difficult task. A hackerspace is not just a space for hackers, a hackerspace is the combination of all those elements.

Hackerspaces and Hacker Culture

It is not uncommon to begin the history of hackerspaces in Germany in 1981 with the founding of Chaos Computer Club by Wau Holland or to try to find ancestors in the U.S. by referencing projects like the New Hack City, the L0pht and others (Schneeweisz 2009). Nonetheless, the first examples of hackerspaces as we now know them, were founded in the mid 90's in Germany, and these were the c-base in Berlin and C4 in Cologne.

These spaces, according to Nick Farr (2009), took a decisive step, they opened up to society, and started an open relationship that proved "...Hackers could be perfectly open about their work, organize officially, gain recognition from the government and respect from the public by living and applying the Hacker ethic in their efforts."

The novelty of spaces like C-base, C4 and the spaces they inspired, is their relationship with society at large and the public visibility and dissemination of hacker culture, which is, ultimately, the importance of the hackerspace (Farr 2009).

Hacker culture dates back to the fifties and sixties and over the decades has been evolving through different generations. Steven Levy (2010) in his book *Hackers: Heroes of the Computer Revolution* gives a detailed account of the birth of the hacker culture and its history. Levy is most famous for his formulation of the hacker ethic, a particularly important piece of hacker culture.

This hacker ethic among other aspects was based on freedom, access and circulation of information and knowledge, distrust of authority, promotion of decentralization and the belief that computers can create a better world (Levy 2010).

The recent history of hackerspaces has a pivotal development around 2007. In this year, dozens of American hackers made a visit to some German and Austrian hackerspaces, with the purpose of importing the hackerspace model to the U.S. This expedition resulted, ultimately, in the founding of some famous hackerspaces, including NoiseBridge (San Francisco), HacDC (Washington), NYC Resistor (New York) and to what Nick Farr (2009) calls the third wave of hackerspaces.

After that, the number of hackerspaces grew quickly and consistently considering the numbers available on hackerspaces.org, which is the most complete information source there is about the phenomenon. In the beginning of 2007 there were something like 30 to 40 hackerspaces, today, as of this writing, July 2011, there are 480 active hackerspaces all over the world, with special incidence in Europe and the USA (Hackerspaces.org 2011).

Cultural Resistance

The most common conception of resistance in social theory is the emancipatory opposition to domination (Hoy 2005, 2). The word by itself can mean exactly the opposite too, it can mean, the resistance of domination to emancipatory efforts. In this sense resistance is just an opposition of a force to another (Hoy 2005, 2).

In the context of this paper we are using resistance in the first sense, the most common one, in the sense of opposition to domination. Furthermore, the resistance we address here is what can be called

cultural resistance and has been described by Stephen Duncombe (2002, 5) as “culture that is used, consciously or unconsciously, effectively or not, to resist and/or change the dominant political, economic and/or social structure.”

The issues we are about to describe and discuss, are examples of the way hackerspaces and, the hacker culture they represent, resist the dominant political, economic and social structure. Despite the fact of claiming political agnosticism (Schneeweisz 2009), hackerspaces influence the cultural discourse, by creating living spaces with a shared culture that is at odds with the dominant models. This act can be seen as a political act.

Cultural resistance, as Ducombe (2002, 6) remembers, can be thought of as political resistance, since cultural resistance is mainly a rewriting of a cultural discourse, “a shared set of symbols and meanings, that we all abide by”, which some argue is essentially what politics is.

In this section we will present some examples of shared values and common practices in the hacker-space movement. With this we'll try to show what exactly is this hackerspace culture and in what way it resists the dominant structures.

COMMUNITY

As discussed previously, community is inherent in the concept of hackerspace. For us, as well as other authors (Moilanen 2010), hackerspaces act as a third space, a space that people go to as a place between home (first place) and work (second place). These third places serve to satisfy essential needs of socialization that are felt strongly and increasingly in contemporary societies (Oldenburg 1999).

This aspect of hackerspaces is one of the possible explanations for the success and expansion of the concept worldwide. Hackerspaces are like sanctuaries in a society that is losing the community reference. The importance of community is widely recognized in reports made by members of hackerspaces. Mitch Altman, for example, said, quoted by Dylan Tweney (2009), “in our society there's a real dearth of community (...) [at hackerspaces], people get a little taste of that community and they just want more.”

GIFT ECONOMY

Underlying the concept of hackerspace we also have the concept of sharing. Sharing space, sharing tools, but most important knowledge, information and time. If we analyze the behavior of members in hackerspaces we see that there is a culture of sharing that underpins all the activity and goes beyond the members themselves, opening up to visitors and the outside world.

In hackerspaces skilled members share with the newcomers their knowledge so that they can pass the knowledge onto others, and so forth. This is done without any warranty or agreement that the person that helps will in the future be helped in return. This, however, does not paralyze the free exchange in hackerspaces. This economy works because there is confidence that others will do the right thing when the time comes.

Hackerspaces are an example of a gift economy, an economy where several goods and services, namely information, knowledge and time are transferred without an explicit specification about future rewards. This contrasts with both market and barter economies.

This gift giving practice goes beyond the immediate community, is how they relate to the world. Due to this, hackerspaces are especially found off open source and creative commons. What is not surprising since they are all gift economies and derive from the same culture.

MAKER SOCIETY

We live in a consumer society where the need to buy new things is all around us. Companies carefully plan ways to encourage consumers to buy new products, even when the old ones are still fully functional, in what became known as planned obsolescence. Consumption patterns are increasingly part of the way people perceive themselves (Featherstone 2007).

But not so much in hackerspaces. Karin Kosina (2009) of Metalab, one of the most well-know European hackerspaces, says that Hackerspaces are saying to the world “Stop being a consumer! Start to be a creator!”

D.I.Y. (do-it-yourself) culture is deeply rooted in hackerspaces. Why buy something when you can make it? But many times the motivation to make something is not financial. As Karin Kosina (2009) states “there is an incredible joy in building something with your own hands, of saying, 'I made this', and unfortunately most people in our society today have forgotten it, have never had it, and we want to give this back to the world”. To make something instead of buying it gives the creator a sense of accomplishment, increased confidence and power.

At the same time open source digital fabrication projects, such as the RepRap or the Makerbot (born in NYC Resistor, and extremely popular in hackerspaces), which allow people to print real plastic objects based on designs they can make on a computer, changes the relationship between production and consumption.

To re-use old hardware is common in hackerspaces too. Hackerspaces receive and seek computers, controllers, synthesizers, electronic equipment, among other things, which individuals, businesses and universities no longer use. When the equipment is still functional, it can be used for their initial function, when they are impossible to fix, they are dismantled and become a source of raw material for new projects.

To re-use and re-purpose is crucial to have a working knowledge, it's necessary to understand how something really works. This need to know, this insatiable curiosity is crucial in defining what a hacker is, as Bre Pettis, founder of NYC Resistor, puts it, “...we break things to understand how they work, share whatever we've learned and make stuff with whatever we can find.” (Schneeweisz 2009).

It's necessary to keep in mind that hackers work primarily with technology, and that technology is one of the more important motors behind human development. About this, Jens Ohlig, famous for the Design Patterns for Hackerspaces, says "is a very radical thing to take technology and use it in a way that is utterly non-economic (...) take the thing that may shape our future out of the economic sphere and control it" (Schneeweisz 2009).

This perspective of re-use, of production for self consumption, of being aware of the importance of controlling the technologies that shape our future does not fit well with the capitalist system, and companies would like to keep people in the state of eternal and passive consumption. Their profits depend on it. That's why they create restrictions, such as seals, to prevent products from being opened, studied and improved. And hackers just hate that.

EDUCATION

This is a field where hackerspaces are especially seen as innovative and as potential contributors to the discussion of future improvements. With the traditional model of education under attack, for not being able to teach what's necessary to succeed in the modern world, hackerspaces with their informal structure seem at least a good complement.

There are several ways people learn in hackerspaces, like workshops, lectures and presentations, but also by collaborating with each other and researching.

Hackerspaces present a learning model that is based on peer-learning and in project-based learning. Members of hackerspaces learn from each other in a horizontal format, where today one teaches and tomorrow one learns.

Also in hackerspaces people learn by doing, usually in a context of a project they want to do. This approach has a specific advantage because one does not only learn something, but learns how to learn.

To be in a place where knowledge is valued, where knowledge is applied, where people feel good about learning, sharing, collaborating, researching and making things is the most decisive factor in creating the right atmosphere for personal development.

With these examples, and more could be presented, what we tried to do was to show the contribution made by hackerspaces to the cultural discourse. These are just some of the issues and we can see that they apply to many fields.

There is a way of seeing the modern world that resists the dominant models. Many people are unaware of these alternative ways of thinking and doing. In hackerspaces there is a critical view of the economy, society, education, among other things.

We can say that, essentially, there is a understanding of what is to be human in the contemporary world. The hackers themselves are aware of this, Karin Kosina (2009) puts it this way "Hackerspaces are physical places for people to get together and tinker with technology, to learn new skills, to share their knowledge, to explore new ways of living together as a society. This is what being human is ultimately all about, creating knowledge and sharing knowledge."

This is what we consider to be an attempt to rewrite the cultural discourse through practice, through a living example.

Conclusion

Hacker culture is alive and well in hackerspaces. We know that many aspects of this culture are not new. The novelty, here, is that hackerspaces are expanding the influence of this culture through open and public spaces that are not cut from mainstream culture. And they keep growing all around us.

We have seen that the values and practices of hackerspaces show that their members have, in a more or less conscious way, critical insights into the functioning of society, economy and education. This vision is not expressed through participation in political parties or movements but rather by creating spaces where this vision can be realized.

These spaces are not closed structures, hidden, constructed to perpetuate the purity of their values. They are, on the contrary, open structures in contact and constant dialogue with society. This makes the values and practices of hackerspaces known and available to society, showing that there are still alternatives to the dominant cultural discourse.

This is the way that hackerspaces resist. The extent to which this form of cultural resistance is more effective than political activism is something that can be put into question. The way we may judge their effect is through engaging topics like the future of education, intellectual property rights, consumer society, new forms of political participation. These are questions in which the experience of hackerspaces can be used to shed a different light on the subject. But for that to happen further research on hackerspaces has to be done.

The third skin – a medium or a mess(age)?

Eckehart Loidolt

Starting with samples derived from the history of architecture illustrating the key topics of buildings as 'the third skin' of mankind the presentation then jumps into main several questions for building envelopes such as protection, function, energy and meaning, facing several different contexts of today.

Opening a second stream of arguments, the statement dives into the wide field of 'architecture parlante' elaborating on sense or non-sense of narrative elements in architecture by balancing out their pros and cons. Ever since buildings have been experienced by passers-by through their façades which are physically defining public space, their genuine expression has been an important issue, though it has not always been treated carefully enough.

After bare Modernism and exuberant Postmodernism new tools and materials were entering the domain of building expression. Leaving aside the glittering world of commercial advertisement as well as the 'night-beauties' illuminated by artificial light when electricity entered the cities in the last century new forms of building-related, adoptive media communication get illustrated.

Looking at the exciting allures of present media-façades the inevitable question of content is introduced and exploited. Are we able yet to talk about new and reliable models of social interaction defining a media space or do we only face a variety of electronic attractions blurring the meaning of public space?

Pointing out durability and beauty as key issues for the longevity and life-span of building solutions the glittering media appearance in architecture is reflected upon critically. In this context the wide range of moveable functional parts in building envelopes researched on and gathered into the 'Move'-book at Prof. Michael Schumacher's department at the Leibniz University in Hannover (D) is illustrated as genuine means of today's architecture.

AESTHETIC AGENTS: EXPERIMENTS IN SWARM PAINTING

Justin Love, Philippe Pasquier, Brian Wyvill, Steve Gibson & George Tzanetakis

We introduce a swarm-based multi-agent system that produces expressive imagery through the use of multiple digital images. At birth, agents in our system are assigned a digital image that represents their *aesthetic ideal*. When groups of agents with different aesthetic ideals occupy the same canvas, a new image emerges through the convergence of their conflicting aesthetic goals.

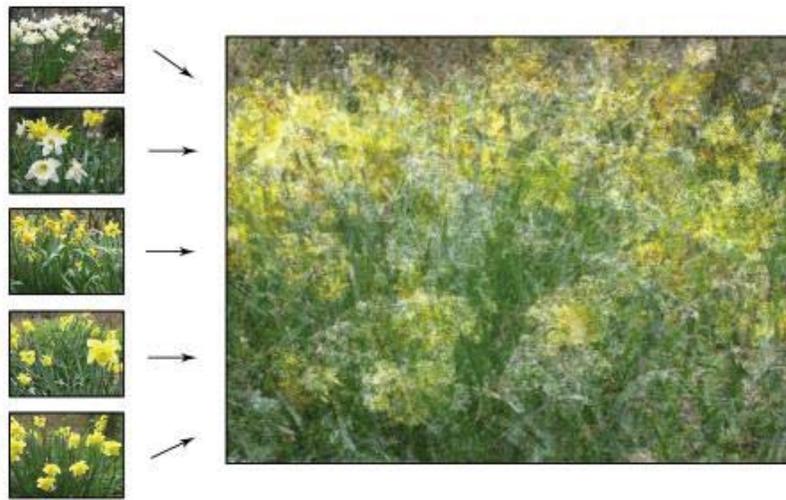

Fig. 1. 'Aesthetic ideals' (left images) for five different groups of Aesthetic Agents and the output (right image) their interaction produces.

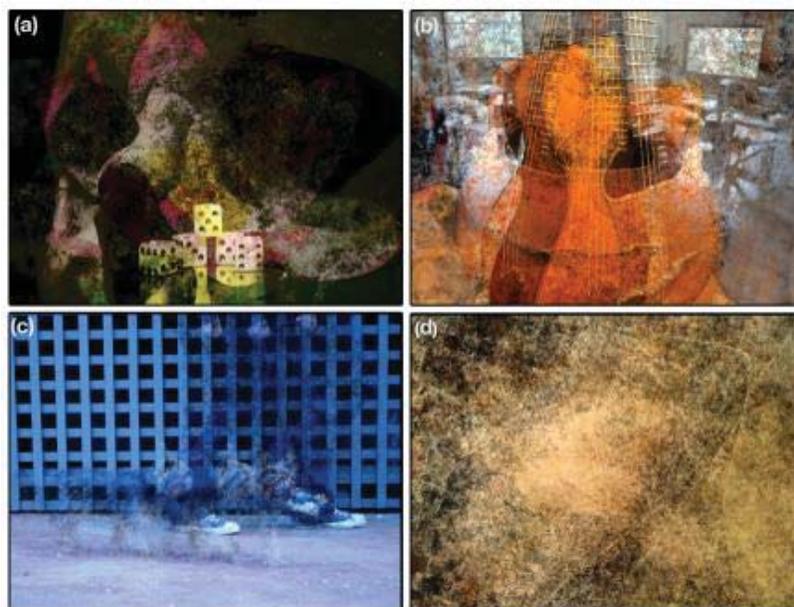

Fig. 2. Examples of (a) Montage, (b) Cubist, (c) Futurist, and (d) Abstract Expressionist inspired swarm paintings.

Background

Our system uses autonomous agents to model swarm intelligence for the purpose of non-photorealistic rendering – a category of research we will refer to as Swarm Painting.

NON-PHOTOREALISTIC RENDERING (NPR)

Where traditional computer graphics has focused on photorealism, NPR looks to artistic styles such as painting, drawing, animated cartoons, and technical illustration as inspiration. In addition to its expressive qualities, NPR can offer more effective means of communication than photorealism by adopting techniques long used by artists e.g. emphasizing important details and omitting extraneous ones. [1]

AUTONOMOUS AGENTS

An agent can be defined as “anything that can be viewed as perceiving its environment through sensors and acting upon that environment through effectors.” [2] An autonomous agent is an agent that can operate independently and is capable of controlling its actions and internal state. Agents can be grouped into two general categories: cognitive agents and reactive agents.

Cognitive agents have an explicit symbolic understanding of their environment and can be seen as an extension of symbolic AI techniques. An example of a cognitive or intentional model is BDI-architecture. In a BDI-based model the beliefs, desires, and intentions of an agent forms the basis of their reasoning process. [3]

Reactive agents are specified by their behaviour i.e. how they react to perceived stimuli in their environment. In a reactive agent model, rules map perceived input to effectual output that is generally executed immediately. Purely reactive agents have no internal history or long term plans, but choose their next action solely upon the current perceived situation.

Each model has its advantages: cognitive models provide more powerful and general methods for problem solving; reactive models are faster and capable of producing complex emergent behaviour from simple sets of rules. [4]

SWARM INTELLIGENCE

Individually, social insects such as ants and termites appear to behave in a simple, almost random fashion. However, when a colony’s collective behaviour is examined complex and seemingly intelligent global behaviours emerge. Initially, it was assumed that the insects were either communicating in an undiscovered fashion or that each individual had some kind of internal representation of a global plan. However, research in the biological sciences has determined that the behaviour is in fact the result of individuals working autonomously with only local information. [5]

One way that collective intelligence can emerge is through stigmergic interaction. Stigmergic interaction refers to spontaneous, indirect coordination between individuals that occurs when the effect of an individual on the environment can influence the actions of others. [6] An example of this is the pheromone

trail that an ant creates on the way back to the nest after it has found food. The pheromone trail attracts other ants who reinforce the trail with their own pheromones. Pheromones fade over time so once a food source is exhausted the trail to it disappears. This seemingly simple heuristic is so effective that it has been utilized to solve a number of combinatorial optimization (CO) problems, including the well know traveling salesman problem.

Swarm-based algorithms have a number of properties that make them successful at solving certain types of problems. They are versatile – the same algorithm can be applied with minimal changes to solve similar problems, robust – they keep functioning when parts are locally damaged, and population-based – positive feedback leads to autocatalytic or ‘snowball’ effects. [7]

SWARM PAINTING

Swarm Painting refers to swarm-based multi-agent systems in which a group of software- or hardware-based ‘painter agents’ move and deposit paint or change pixel colour values on a real or digital canvas. Swarm painting can be divided into two main categories: colour-based swarm painting and image-based swarm painting.

Colour-based

To date the majority of Swarm Painting systems have adopted a colour-based painting approach. In a colour-based approach, agents paint a blank digital canvas with pre-determined or randomly chosen colours. The majority of colour-based swarm painting researchers utilize an ‘ant and pheromone’ model. In this model, a colony of virtual ants move and deposit paint on a canvas based on the distribution of virtual pheromones.

Image-based

Another approach to swarm painting is to use an existing digital image as a reference for painting. The use of image files for NPR is a subfield within NPR called non-photorealistic rendering from photographs (NPRP).

The concept of using a digital image as a habitat for a colony of virtual ants was first published by Ramos at the 2nd International Workshop on Ant Algorithms (ANTS 2000). [8] In Ramos’ model, the grey level intensity of pixels in a digital image creates a pheromone map that virtual ants are attracted to. Ants deposit paint as they move and the trails they leave form a sketch-like image that contains salient features of the original image. Ramos’ primary interest was in image processing and not the creation of artistic works. In fact, the majority of research utilizing digital images as a habitat for swarm-based multi-agent systems has been concerned with non-artistic image processing tasks such as image segmentation, feature extraction, and pattern recognition.

Aesthetic Agents

Our system expands on previous research by using multiple images in conjunction with a swarm-based MAS for NPRP. Although our system references digital images for colour information it does not treat them as a habitat or environment. Instead, agents in our system are assigned a digital image that represents their aesthetic ideal. Accordingly, we refer to them as Aesthetic Agents.

On the surface, the behaviour of Aesthetic Agents does not seem to be stigmergic since the aesthetic ideal that agents are assigned can be seen as a global goal. However, the existence of multiple competing global plans produces images that are not the goal of any individual agent. Therefore, images produced by our system are the emergent result of local interactions since agents are not aware of each others goals or the image that will result from their interactions.

Aesthetic Agents are born in a toroidal digital canvas i.e. a 32-bit ARGB (Alpha Red Green Blue) bitmap image. Agents occupy a single pixel within the digital canvas and are invisible i.e. only their effect on the digital canvas is seen. When an agent is born it is assigned a 32-bit ARGB bitmap image that represents its aesthetic ideal. Aesthetic Agents are both reactive and autonomous. They are capable of ‘sensing’ the colour value of the pixel they occupy and those immediately surrounding them (Moore’s Neighbourhood) and can modify the value of the pixel they occupy.

Agents modify pixels through the interpolation of the RGB components in the pixel they occupy in the digital canvas $c(x, y)$ with the pixel at the same location in the agent’s aesthetic ideal $i(x, y)$. The amount of interpolation is based on a preset interpolation variable between the value 0.0 and 1.0 where 0.0 is equal to the first number, 0.1 is very near the first number, 0.5 is half-way between, etc. For example, if the interpolation variable is 0.1 (10%), the RGB colour value at $c(x, y)$ is (0, 0, 0) and the RGB value at $i(x, y)$ is (100, 50, 200) then the pixel at $c(x, y)$ will be changed to (10, 5, 20) by the agent.

To initialize our system we create n agents, where n is the number of input images, and assign each agent one of the images as its aesthetic ideal. Only one agent for each aesthetic ideal is required since the offspring of agents are assigned the same aesthetic ideal as their parent. In our experiments we spawned our initial agents either in the centre of the digital canvas, $c(\text{width}/2, \text{height}/2)$, or at random locations $c(\text{random}(\text{width}), \text{random}(\text{height}))$. For each iteration of the system, agents perform the following actions: Sense Colour & Move, Express Aesthetic Ideal (Modify Pixel) and Reproduce.

Experiments in Swarm Painting

We used our system to explore a number of concepts and techniques from a number of Modern Art Movements.

MONTAGE

Since our system uses multiple images the most obvious visual technique to explore was montage. Montage (French for ‘putting together’) is a composition made up of multiple images. The technique played an important role in many Modern Art movements including Bauhaus, Dada, Constructivism, Surrealism, and Pop Art. To create a montage we simply take n images and assign each one to a different group of Aesthetic Agents. *Figure 2(a)* shows a montage made of an image of a skull, a lotus flower, and dice.

IMPRESSIONISM

Impressionism was a late 19th century art movement based on the work of a group of mostly Paris-based artists including Monet, Pissarro, Manet, Sisley, and Renoir. Some of the characteristics of Impressionist paintings include small, visible brush strokes, an emphasis on light and colour over line, a focus

on the overall visual effect instead of details, and a relaxed boundary between the subject and background. To explore these techniques we set different pictures of the same subject matter as the aesthetic ideals to different groups of Aesthetic Agents. Our intention was to try to combine similar elements of the same subject matter into an abstracted form. *Figure 1* shows an example in which five groups of agents are given five different images of daffodils.

CUBISM

Cubism was an art movement in the early 20th century pioneered by Picasso and Braque. In Cubist artworks subjects are deconstructed and re-assembled in an abstracted form that often depict the subject from a multitude of viewpoints. To explore this technique we took photographs of the same subject from different angles and assigned the different perspectives as aesthetic ideals to different groups of Aesthetic Agents. *Figure 2(b)* shows the result of this technique and the increasingly abstract effect created as more angles and images are added.

FUTURISM

Futurism was an artistic and social movement founded in Italy in the early 20th century by Filippo Tommaso Marinetti. The Futurists admired speed, technology, youth and violence, the car, the airplane and the industrial city – all that represented the technological triumph of humanity over nature. To the Futurists we lived in a world of constant motion, an idea that manifested in their painting manifesto:

On account of the persistency of an image upon the retina, moving objects constantly multiply themselves; their form changes like rapid vibrations, in their mad career. Thus a running horse has not four legs, but twenty, and their movements are triangular.

To explore this Futurist concept we took successive images of a subject in motion and set the images as the aesthetic ideals for different groups of Aesthetic Agents. See *Figure 2(c)* for an example of this technique.

ABSTRACT EXPRESSIONISM

Abstract Expressionism was a post-World War II art movement that is characterized by spontaneity, emotional intensity, and an anti-figurative abstract aesthetic. It was the first American movement to achieve global influence and was largely responsible for shifting the centre of the Western art world from Paris to New York City. Some notable painters of this style include: Jackson Pollock, Willem de Kooning, Mark Tobey, Mark Rothko, and Barnett Newman. Since we had discovered that increasing the number of competing aesthetic ideals in our system leads to increased abstraction we simply needed to use more images to create completely abstracted imagery. We found in general that around ten images is sufficient to remove all of the figurative details from a set of input images. *Figure 2(d)* shows an abstracted image made by assigning ten different images of a reclining nude figure to ten different groups of aesthetic agents.

The above examples demonstrate the importance of image selection to achieve a particular effect with

our system. Although, some of the effects (e.g. Abstract Expressionism) can create interesting results from random image input, others like Montage require more mindful selection to achieve good results e.g. have figurative elements remain intact and still readable.

Conclusions and Future Work

In this paper we expanded upon previous research that utilized swarm-based multi-agent systems for NPRP through our use of multiple images. We successfully implemented a system that is easy to implement, versatile, and capable of producing novel, high quality artistic renderings. In doing so we demonstrated the power of biologically inspired models and metaphors to create new forms of artist expression. Furthermore, the simple implementation and effective results produced by our system makes a compelling argument for more research using swarm-based multi-agent systems for non-photorealistic rendering.

We created our system using a swarm-based MAS, but we are certain that similar results could be produced using another programming methodology. Which begs the question, why use a swarm-based MAS methodology? To answer this we will adopt McCarthy's justification of intentional systems that "although a certain approach may not be required – it can be useful when it helps us to understand and think about systems where a mechanistic explanation is difficult or impossible". As computer systems become increasingly complex we will need more powerful abstractions and metaphors to explain their operation. This is particularly true in the case of modelling emergent phenomenon.

The dynamic nature of our swarm painting system makes it easily extensible to interactive applications. At the time of this writing we are working on a series of interactive installations in which agents are born and populations dynamically change based on input from real-world physical sensors.

In the future we would like to endow our agents with more more biologically inspired attributes and behaviours. More complex movement, feeding, and reproduction strategies will be investigated. In addition, we can extend our current model of an 'aesthetic ideal' to go beyond the colour values of pixels in a target image. Future agent's aesthetic ideal could be based on other visual elements such as contrast, brightness, and saturation or an agent could have a geometric bias towards creating certain shapes. To explore our system we used a number of Modern Art movements as inspiration for our experiments. Future work will explore the innate and unique qualities of our system. Finally, we would like to create Aesthetic Agents that inhabit a 3D world. Groups of agents could be given different 3D models as their aesthetic ideal to create emergent sculptures. Other Aesthetic Agents could add living textures to the 3D forms.

UBICOMPUTACIONAL ART: URBAN ENVIRONMENT AND EMERGENT NARRATIVES

TIAGO LUCENA

This paper explores the art in Post Desktop Era and we propose the term Ubicomputational Art with a new field in Cyberarts for study of junction between Art + ubiquitous computing. The ability of urban environments to add information is also exploited in the art in some collaborative practices. We intend showing some mob applications created like an artwork that allow the user tell stories about place in a new open narrative porpoise.

// UBIQUITOUS LIFE CREATING ONE UBICOMPUTACIONAL ART.

Mobile computing, pervasive and ubiquitous computing are the phases that computing platforms are suffering and will change the how we perceive, share and create information.

The ability of urban environments to add information is exploited in the art in some collaborative practices how construction of maps, mobilization (flash mobs) and interventions in virtual metropolis. We started our journey between this relations: city/mobile technologies by participating in some Collaborative Cartographies, flash mobs and wireless or mobile games or location-based games. All these categories use the technical infrastructure of computer and social networks at the intersection of space virtual and physical. In this field of research, we include our interesting to emergent narratives topics remapping the space of the city by adding new layers of data/information.

This research growing up a new collaborative space of LART _ Art and Technoscience Laboratory (coordinate by Dra. Diana Domingues) in intersection between Art and Software Engineering, Automative, Eletronic, Energy at Universidade de Brasília/ Gama campus. A new space opened at Gama Campus where engineers works together artists in a transdisciplinary methodology pointed by Ivan Domingues, philosopher (2005).

The research about cities environments and arts started in the topic of Arts plus ubiquitous computing systems. We propose the term of Ubicomputacional Art, with a new Field in cyberarts for study of junction between Art + ubiquitous computing. The term of "ubiquitous computing" was proposed by scientist Mark Weiser, in 1991, to designate a profound change in computing platforms. These changes inaugurate other models of computing, where computers are effectively integrated into the environments in all daily practices beyond the uses and behaviors desktop metaphors machines. Weiser used the word ubiquitous, (which means something that is or can be in everywhere, omnipresent) to describe a kind of "computing without computers" (WEISER, 1995). "In his telling, desktop machines per se would largely disappear, as the tiny, cheap microprocessors that powered them faded into the built environment. But computation would flourish, becoming intimately intertwined with the stuff of everyday life" (GREENFIELD, 2006, p. 11).

The UbiComp dawning as a phenomenon in informatics researches e undoubtedly will bring changes in how we deal with things day by day. The data contained in virtualized and Cloud Computing, the mobility of wireless devices and interconnections between things through a structure many networks are

other important features such research and have been observed by us in studies concerning the Mobile Art and the Locative Media Arts (Lucena, 2009). We continue this research, raising the possibility that the matter now in the Art Ubicomp is not only the "mobility" (as it exists in events before the creation of cell phone and its appropriation in art), or wireless connection equipment (laptop, mobile, palm tops) as we suggested before, but the "invisibility" of them. For Weiser "Even the most powerful notebook computer, with access to a worldwide information network, still focuses attention on a single box. By analogy with writing, carrying a super laptop is like owning just one very important book". (1991, p.20). Thus, we approached the Ubiquitous Computing to understand a new art form that rearranges the forms of connection, access to information and the concepts of portability and mobility.

We believe that with these new computing platforms (which includes transparent interfaces, mobile and portable devices, sentient objects and tangible bits) inaugurates a new phase of art. The term Ubicomp is not just the sum of art with ubiquitous systems but also a new mode that is born and a new paradigm for thinking about the relation of art, science and technology.

//ARTS + COMPUTERS

The uses of computational platforms in arts is contemporary with the emergence of electronic computers in the 1950s. The Brazilian artist, Waldemar Cordeiro, was one of the pioneers in this kind of art. The computational art works with computational algorithms, which are commands given by the developers to machines that perform the calculations. These productions sought to exploit the potential in the creation of worlds and synthetic images, the possibility of interaction (at different levels of man-machine), the contacts and dialogues established through human-machine interfaces.

The creative process of creation in Computational Art found himself constantly linked with the arrival of graphic interfaces, which somehow facilitated the work of the artist. The tolls of the computer has opened new kinds of art works and share this works for people using networks. The digitization of data, display screens and the ability to interact with them have added significant changes in the artistic process. We are in diverse experiences, accompanied by persons connected away from us, due in large part, interfaces and technological mediations that put us in the same (cyber)space. In this perspective we followed many telepresence, remote actions and at distance art practices. Indeed with the arising of telematic infrastructure the artists trying to connect the so long places as possible. Now, the artists is looking to the space of connection opened by mobile phones, notebooks and other portables devices to see something and tell about places near where they are.

With the artistic practices that use the ubiquitous computing, it has been clarified so that the means of production change significantly the results of the stylistic art. We propose a look at these events and artistic products, emphasizing the elements that differ from the Computer Art or Code Art. Anyway we have to propose new theories to explain this production in contemporary art. Then follow the directions of Manovich (2001), that to understand the logic behind the new media came of Computer Science.

For us, this new platforms for interaction between man-man and man-machines, has opened new practices of creation in art using the potential of collaborative works in virtual networks.

// BEYOND THE MOBILITY

The use of cell phones in every daily practices is reconfigure our daily experience, putting us in constant contact with friends, family and work's topics. The fact that we can be

connected with everyone, anywhere and hours (not to mention the places where the systems telecommunications cover), makes it possible for us different ways of organizing everyday life. The relations characterized by the ubiquitous network grows in spheres of family, social relationships, work, social services, entertainment, based on selective network (Castells, Qiu; Ardevol and SEY, 2007, p. 126).

The cell phone is today the best example to illustrate how computers came to desk to habit our pockets. This movement is important to create the good conditions for ubiquitous computing in a pervasive world. We believe that mobile phones will act as the remote-control of the others objects placed in our homes, in a dialogue between machines. With the m2m communication, Humans will also interact, conscientally or inconscientally, with a data space around us, machines will transfer information. "Cyber-space is in everywhere" said William Gibson (2007).

Apparently invisible, computers are "populating" the homes, offices, streets in smart environments, pockets and in many other portable technologies. Reserved in rooms in 50s, computers today keep the relation: many computers for one person. Now the computer and the room are the same thing.

In dealing with the computer in the Post-desktop Era will not do so only through the manipulation of data through the screens of monitors. The mouse and keyboard still stand between man and machine. In Ubicomp, computing will become so intuitive and transparent that its interface will deal with data without having the awareness of such action. The computer "disappear" and goes to the "peripheries".

Weiser points out that the disappearance is a fundamental consequence not only of technology but also of human psychology. When we look at a street, the author quotes, information just evil deeds "without consciously performing the act of reading." This feature has been called various names (compiling, tacit dimension, visual invariants, horizon and ready-to-hand) by computer scientists, psychologists and philosophers. We prefer to use the term of John Seely Brown of PARC that calls such as the quality of being in the "periphery".

Works in art, that work in these lines of investigation illustrated by Rheingold (2002) could be also include as expoents of Ubicomputacional Art, :

1. Information in places;
2. Smart Room: ambient that feel the presence of the person and answer for it;
3. Digital Cities: urban places are able to add digital information in places to help people to walk, to access information about places, services, new practices of e-government, m-government;
4. Sentient Objects: add information and communication ability in physical objects;
5. Tangible Bits: manipulating virtual world by physical objects and
6. Wearable Computing.

The ability of urban environments to add information is exploited in the art in some collaborative practices how construction of maps, mobilization (flash mobs) and interventions in virtual metropolis. Collaborative Cartographies, flash mobs and wireless or mobile games or location-based games use the technical infrastructure of computer and social networks at the intersection of space virtual and physical. In

this field of research, we include our interesting to emergent narratives topics and the concept of the Urban Mixed Realities worked by Rod McCall (2008) and his group.

The readings on the relationship, between physical and virtual space, is also important the concept of Cybrid (Hybrid + cyberspace), proposed by architect Peter Anders (1999). We follow Diana Domingues (2008, p. 6) when she says that the "qualities the environment using a mix of computers and interfaces that take action in co-existing in space and material digital space, in physical space and data space. "For us, the focus of the research of artists and scientists in the ubiquitous world is in the mix of technologies to places. These include so many devices cell phones, palm, notebook computers) and vehicles (SMS, GPS, MMS, e-mail) "that are no longer limited to rooms and offices with fixed equipment, put the computer the periphery by the possibility of locate and to be located. Are the mobile and locative technologies that alter sense of place, time, space "(p. 5).

As background to our work we can localize some location-based games and wireless mobile games. The proposal to link to content in places began deposed our interest in investigating other examples in history of the arts. It read in this relationship between art and the city the work of international Situationists and various other interventions / performances that call poetically attention to the places.

// THE MOB APPLICATION: TAKING THE URBAN SPACE AS A SHARED SPACE FOR PEOPLE TELL STORIES

The user-generated content is configured as a trend in the use of digital communications technologies and information. There are several sites, computational tools and platforms that allow users to create, share and comment on content created by other users.

The participation reaches high levels with the incorporation of mobile phones the computer network. Armed with mobile devices, which can be compared to laptops, people have the sense of presence and enhanced participation by means of tools that allow you to upload any content to the cyberspace from anywhere. The mass self communication (Castells, 2006) are the concept related to production decentralized, and no generalized "mediators."

No less interesting was followed by the incorporation of art and media that also allow the viewer's participation in the process of artistic enjoyment. Something that had already been appointed from a participatory art movement, with various demonstrations that used sensors, cameras and objects to the viewer to touch, feel the art-experience. The interactive art, opened especially after the use of computational resources from the 60's, puts the viewer and the work as a spectator to participate in building the image, the creation of audio effects in a variety of experiences and conditions: multimedia installations, webart, gameart among others. With the rise of cellular proposes a kind of Art in Mobile Media, which has received other names as Mobile Art and Art in locative media. More precisely in the use of mobile devices, many of these demonstrations did not invite the viewer to only trigger pre-recorded images and sounds, but to send images and sounds created by themselves providing geolocated data, being "followed" and "follow" other users in finding information.

Relations characterized by the ubiquitous network are given in the spheres of family, social relationships, work, social services, entertainment, based on selective network (Castells, Qiu; Ardevol and SEY, 2007, p. 126). In art, think about the marriage between participation of users sharing experiences and experiences with the constant connection and mobile afforded by telematic networks. Thus, the aim of

this report is to present the process of creating a mobile application called AQI!. The Project Emergents Narratives in Urban Mixed Life: Creating computing platform (mobile app + site) to create / count stories about cities was born of questions and seeks to participation and interaction of users in generating subjective content for mobile interfaces and tools that facilitate sharing information. It has as its central objective the construction of a platform, composed of mobile application AQI! plus site, for individuals to create, share and visualize stories. A geolocated story where the user lives. The project is open to the creative use of stories and lets users fiction are also created. They are user-generated content in ownership of tools that can be exploited in building social communities and networks. The stories are visible encouraging participation and collaboration with another user. The content published may be text, image or video.

The mobile application AQI!, developed as part of this project was built on the Android platform in the Java language and uses the Google Maps Android API, which displays the same geolocated data displayed on the website. The design is user-centered, to create a comfortable interface for any operator (Saffer, 2010). The data are retrieved in XML and HTML server using HTTP. The application also lets you send data directly to the server. By surfing on the Web, other users can participate using the website created to access and creation of content. The website was developed in PHP and JavaScript, using Apache webserver and PostgreSQL as the database manager. In addition to providing the public information about the project, enables the visualization of geolocated data by Google Maps API and provides an interface to these data for use in mobile app.

This creation of "worlds counted" and stories that encompass the context and the use of mobile phones to tell stories, tries to generate narratives by people in diverse locations, furniture, has as reference "Free the Monsters of Manchester." The project consists of a "campaign political action" by the monsters who lived in the area covered by the City of Manchester long ago, in the industrial revolution but are now "Trapped beneath the tall buildings made of bricks and stones and cement." Manchester residents are invited to take part in the campaign, choosing a place in Manchester, wondering what kind of monster would ever have lived there, and putting the monster in place using the system Anywhereblogs. Users are reminded that: "Monsters are released as soon as you conjure" (Wilson and Hales, 2008). Once a monster is imagined and written about He was found by the people, then it exists and is as real as any part of Manchester. The monsters released are tagged on Google Maps.

In the spatial movements of mobile phones across the cities realizes that the connectivity of the device itself replaces the stereotype of the Internet connected to the PC front, sedentary at home. Some examples in mobile art the displacement of virtual character is only performed with an equivalent shift in space physical performed by the user / player. So these games do not even require only physical movement of the players they are also tools to meet people, make eye contact with others and the appropriation of examples urban fabric as a board.

The same principle is proposed in the AQI! the creative use of GPS, which allows the application accurately identifies the approximate location where it is found. Thus, when designing narratives in the urban environment, to enable urban environments to make available information. The use of virtual maps and geo-located platforms (GPS) allow become "discoverable" the viewer and creator of the narrative. In addition, another important precedent was with the workshop given in the city of Passo Fundo - RS, called Narrative cybrids, mobility technologies and urban life mixed coordinated by Diana Domingues. Where workshop instructors were allowed to think and create stories that emerged in the exchange of SMS, MMS walks in the streets and in meetings with local residents and city in the

State. An interesting quality of the AQi! is given the possibility that people can, and create stories, report the problems of their city, dissemination on the world wide web and collaborating with others in the construction stories. AQi is one mobile application for Android based devices versions 1.6 or higher. Models equipped with GPS and compass. Connected to Internet through the network 3G or wireless plans. It is intended for any user interested in share some event of his life in a particular location or create a story about a particular place, showing new possibilities to the relation between urban spaces and opened narratives. Users can create their stories through the use of the web, and from the phone itself. Stories are shared and open to collaboration with other users. In addition, anyone can comment, quote and build together with others in a process collaborative writing stories.

Integrating arts experiences and biomedic engineering at Brasilia University, acting in LART we proposed the collaborative project called CidadePathia (something like Pathos of the City). This conceptual project will be a intelligent system in u-health (ubiquitous health) that select some biological data from citizens from Brasilia. The system select some data from users using biomedical sensors and mobile phones, this information will be upload to one map that allow people, urbanists and health professionals to see where and when some diseases appear. Of course, combining some of these biomedical data we can know if the citizens are stress, calm or having heartbreaks. For now, is just one project that follow the ideas from AQi! In this kind of integration between intimate or documental stories with urban space.

Fig 3. Dance position with dance notation (Benesh)

Humans have a unique ability to build formal languages. We use them to both communicate among us, but also to communicate with the machines we assemble. Computer programming languages and natural languages are both formal languages. Nonetheless they stay at the antipodes: one is close to our anthropological way of communicating and the other is close to how the inner machine logic works. But, they both instantly establish an understandable abstract environment to describe processes. Their point of contact is centered in the way we're able to write programming language code closer to our natural language (English is the universally adopted one) transversally modifying the way we formulate what we'd like the machine to do, and so generating a significant output. This formulation is a hybrid territory where pure language, explicit dynamic structures and simple to complex formulas collide. Loops, cycles that run depending on value-driven decisions are outputting computed meanings. Words and numbers, meaningfully sequenced are directing the formation of a text, a drawing, a picture, a sound, a movie, or a combination of all the above, with the programmer acting as an open scriptwriter and the user acting as a temporary director and spectator at the same time. These two actors (the programmer and the user) have an invisible and time-delayed relationship that is defined through the programming code, and the same code embodies the many adapted and twisted senses mutating the natural language. This is the territory where historically "software art" steps in. Playing with language and its power to generate impressive output thanks to its ability to use a readable formal language, that is potentially generating infinite sense (as the natural language does).

1. SOFTWARE ART, USING FORMAL LANGUAGES AS ART

Software art ancestors have been retrieved in the seventies, among the artists ascribed to the conceptual and performance art movements. And that now sounds quite plain to see, as they were art movements dealing with language at their core. Particularly "Draw a straight line and follow it" is one of the celebrated conceptual artworks by the composer La Monte Young. It's a small masterpiece as it can be seen as a music score, a piece of visual art, a poetic text, a performance. [1] "This piece can be called a seminal piece of software art because its instruction is formal" Florian Cramer and Ulrike Gabriel claimed in their seminal "Software Art" essay in 2001. [2] Technically it can be defined as a loop, more

precisely an infinite loop that generates a proper half-line, with a fixed origin and a straight direction with no end. It's a concept expressed in natural language, but it perfectly describes the structure of a typical computer programming loop (do something infinitely or until something else happens). Its endlessness has an intrinsic dynamic that is a peculiar software characteristic: dynamically designing a process and enabling the dynamics precisely generated by the software itself. The code becomes then a script infinitely variable as the natural language is. And code becomes a pure linguistic performance, in this perspective. In recent years artist Mary-Anne Breeze has epitomized this approach. She created the "mezangelle", a language composed with hybrid words (conceptually close to the portmanteau words invented by Lewis Carroll). [3] Moreover in mezangelle the words are not only condensed but they also recombine language, stacking multiple layers of meanings into single phrases. This is accomplished hybridizing formal code and informal speech into a condensed textual space (like, for example in "[vec]Tor[n]Space_[di]Stancing"). She cut forms, conventions, phonetic spelling, abbreviations and slang used in the internet culture at large and grafts them onto regular words in a still readable way. These alterations don't follow fixed syntactic or grammar rules but more a very coherent "style" that is instantly recognizable. The poetry and the discourse she composes are an ever changing morphological synthesis of different formal languages into a variable one that embodies the tremendous potential and dynamism of them combined in a different way every time she writes a new text. That's why the initial dilemma of how to categorize art made with software (involving telematic networks or not) has been generally solved sorting it as "performance," that meant to preserve its essential dynamism. In fact considering software as a performance means to acknowledge its linguistic properties, including having a beginning, (at least potentially) an end, and a process that goes on between the two. Moreover it means also to definitively recognize the strategic role of the instructional code and its literary gesture, involving scripting entities and events that form the process. The result is always formal, being it natural language, code or a hybrid one, but it's nevertheless written in a universal and unambiguous language.

2. DANCING CODE

Software can be then defined, with no doubts, as a dynamic process. It can describe an infinite type of processes in a formal language making the computer calculating the output, basing on some input. Now let's consider the dance practice as a process. Especially popular type of dance is often quite formalized through a recognizable code that anybody can follow. There are a few notation systems for describing dance, but none of them are acknowledged as a major standard, and universally acknowledged. The best known are the Labanotation and the Benesh Notation [4] and they use abstract symbols to specify the position of body parts, their direction and the speed of movements. Every notation system has developed its own array of symbols and syntax to generate a shared formal language to express the "set of postural and motion rules to define how the execution of the movement is to be applied." [5] The finite sequences of these symbols are describing an animated sequence of a body performing a choreography with its own embedded narrative. Here the space, where the body is moving, has to be precisely described and the used codes are rendering the space's different peculiarities in a symbolic way. Nevertheless the whole sequence of a notated choreography is a code that functions in a very similar way a software program does. It needs the body as the input and it generates an output of a whole animation of movements in space. Dance is then animating the body through a code and it expresses the smoothness of transition between the start and the end of an event, with all the dynamics in between. Seen through an anthropological perspective, the "code" of dancing practices (feet and body positions, and the sequence of movements) has been historically spread through an oral tradition that in the 20th century has eventually become viral. The description of entities and their movements has been assumed to be learnt by heart (almost in its literal sense), to be then stored and transmitted

eventually with variations. It has been a social process with dynamics similar to what FLOSS (free/libre/open source software) programming is nowadays: acquiring a code, using it, eventually modifying it and vastly sharing it. So it'd not be any accident if computer programming, FLOSS, dancing and social aspects would collide in some ways.

3. PROGRAMMING ANIMATION IS A WRITING (MOVING) PROCESS

So can we consider "computer animation" (the process of programming the movement of different objects on the screen) a form of choreography? Probably yes. Programming animation on a screen is definitely similar to notating or coding a dance choreography. Nonetheless in computer animation the human body is abstracted into any kind of programmable forms, and the space is a virtual three-dimensional one, visualized in the two-dimensional screen. Computer animation can be then considered as an "abstracted dance", since the principles of movement in space remain the same, generally including the physical law we obey to in physical reality. But it retains some specific characteristics of "dance", for example being based on harmonic movements that are expressed through a timeline and strategically positioned in the virtual space, with a peculiar narrative. Beyond that, programming computer animation is an activity that implies some computer programming skills, or being able to describe processes in a computer language code. If historically it has been made in programming code that was very close to the machine logic, one of its major popular shifts has been accomplished in the nineties with the Adobe Shockwave [6] platform. Making animations in Shockwave (with the historical characteristic of being viewable for the first time within any web page through a standard plug-in) involved learning the script proprietary programming language called Lingo. [7] Despite that, a substantial wave of animations was produced in the first wave of the web, and for cd-rom supports as well. In the years two thousands the awareness of the FLOSS (free/libre/open source software) community produced new types of platforms, including openFrameworks, [8] founded by Zachary Lieberman, [9] that were able to move this coding practice to another level of social interaction. Lieberman noted that he spent his childhood in a printshop. That made him aware that a printing machine, indeed a powerful machine to produce content on a medium, is not something that can be easily owned by a single person, because is too expensive and definitively too heavy. It has to be eventually shared, capitalizing, both socially and economically, on the small community that can be formed around it. He learned as a kid that sharing content producing platforms and skills was the key to improve knowledge and produce beautiful products.

Lieberman engagement with computers and code led him to program animations, and teaching how to do that, in a peculiar way. He considers it a social process, more than a mere technical or educational one. That is evident in his personal research developed working with magicians, in order to help them integrate digital technologies in their public performances. Magic has different distinctive characteristics. It involves deception, because it involves distracting our attention and senses from what is being manipulated. There are also strict rules as, for example, that visual tricks are usually never unveiled, except among the practitioners. But magic involves fascination, and especially being in the mood to let ourselves be fascinated. Still magic is also something experienced in public, and it's an emotional experience. Once shared, it can be a terrific medium of communication for its perceptual involvement, and somehow it's already exploited in communication to wake up the spectator's attention. But again it is a language skill. And it means to share a common language. Once the people involved are comfortable with a language and a grammar they can communicate, collaborate, share and build systems together. Somehow that almost literally means to bring life to code. If anthropologically building machines that seem to be "live" means to us to construct something with its own moving autonomy, for our senses building a system that contains autonomous entities that follow their "code"

to act, is one of the closest situations where to consider that system as a "live" one. Generating this kind of artificial life is close to our instinct that pushes us to build sophisticated machines that resemble our behaviors. Programming code becomes then the esperanto for building autonomous systems that can rely on the beauty and "magic" of animated objects, unifying a small community around its efforts of creation and simulation of "systems."

4. PROGRAMMING LANGUAGES CAN BE SOCIAL INTERFACES

Language is our most used social interface, but under the proper condition, a programming language can be a social interface too. In the case of openFrameworks, the code, developed under proper FLOSS conditions, becomes social for various reasons. First it relies on an active community that supports it and guarantees its technical update and management. Moreover, when dealing with animation, it deals with an activity that can be "socially" processed as dance historically has been done. Finally quoting Lieberman "we're moving away from objects, we're building systems." The dynamic environments built in open platforms like openFrameworks are shared and constitute micro-worlds that include the internal relationship, as small virtual communities. The process of building them can reflect the social communities outside these environments and reflect them both in the functioning models applied and in building and sharing them through the developing community. There are interesting social consequences for these practices. One is how language (any hybrid one can make by computer code and natural language) can build dynamic social systems and compelling animations beyond enabling a simple communication. And another one, even more important, is the crucial awareness that a temporary or fixed community can build a system, sharing it and using it, or improving it at will. Designing systems collaboratively can then change the communication we usually use. Staying free under these conditions we can become a multitude of test beds on how we can change ourselves and our cultural neighborhood.

THE FLUCTUATING BORDER BETWEEN ARCHITECTURE AND THE BODY IN SHIVER

Colleen Ludwig

Shiver is an immersive, interactive environment that uses physiological and psychological aspects of skin as visual metaphors and sensory mechanisms. The edge between body and space forms an ever-present, fluctuating borderland. My research on skin biology and the phenomenology of space results in a work that engages the body surface, activates the senses, and brings the body into direct relationship with its environment.

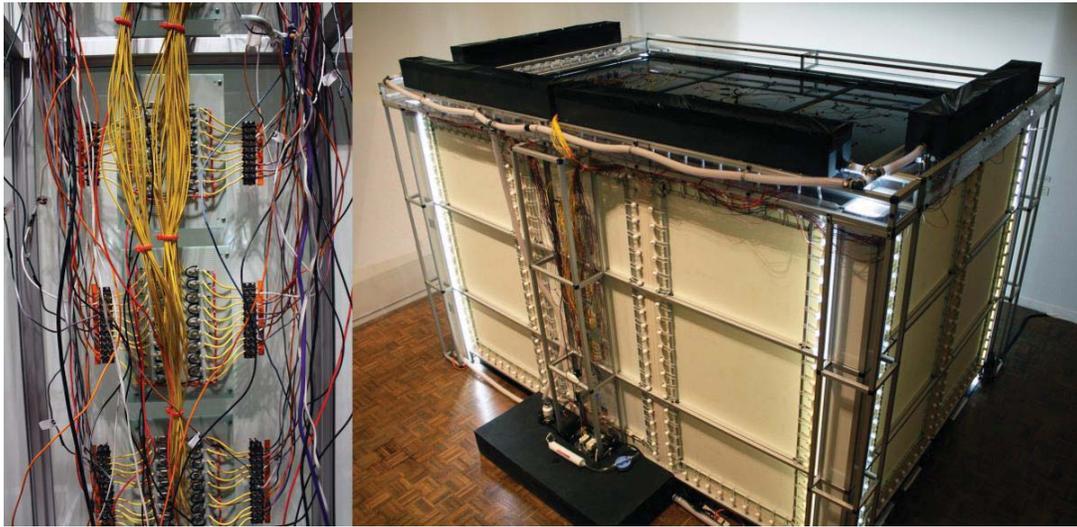

Fig 1. Shiver, exterior and detail, 2011, Colleen Ludwig, aluminum framework, fabric, plumbing, electronics and programming, 10' x 14' by 12.5'. Photographs by Colleen Ludwig.

Fig 2. Shiver, interior and detail, 2011, Colleen Ludwig, aluminum framework, fabric, plumbing, electronics and programming, 10' x 14' by 12.5'.

Shiver is an immersive, interactive environment, that integrates programming, electronics and a recirculating water system into a pre-fabricated, architectural framework with specially treated fabric walls. The resulting room is filled with cascading water flows, which develop organic patterns and conjure an impression of compassionate space. *Shiver* is a meditative place for mindful sensing of the body as it integrates itself into the surrounding environment. I created this artwork to poetically articulate the fluctuating border between architecture and the body. It is the first room in a series called *Elemental Bodies*. Each of these rooms set conditions which ask participants to experience their skin as a mediating border between viscera and atmosphere. [1]

Upon entering the artwork, visitors activate trickling flows of water. A sensor matrix in the ceiling tracks people as they explore the room. That data is used by microprocessor software to move the vertical water flows along the walls in response to a visitor's position. Individual streams naturally form curvy rivulets that cling to, and creep along, minor topographies in the water-resistant fabric walls. The patterns are similar to what is seen on wet human skin. Due to surface tension and capillary action, the flows bulge and contract slightly, giving them a shivering effect.

Groups of contiguous water streams form *nodes*, which grow from a central stream to widths of 3, 5, or 7 streams. Nodes get bigger as you approach a wall and smaller as you withdraw, creating the illusion of water emerging from, and receding into, the wall membrane. Multiple kinetic responses of the water flows in *Shiver* encourage participants to walk slowly and change vantage points, in order to cause the room to react in different ways. Although the exterior is heavily equipped with mechanical contraptions, the water formations enliven the interior space and bring primary focus to the organic. The effect can be both soothing and unnerving, as the beautiful, watery forms invade a space we expect to be dry and neutral. The invitation to touch the flows is implied, but not stated. This adds tension, as each viewer must weigh the desire to touch the water with possible unintended consequences, including wetness, surprises, altering the water paths or breaking the piece.

The physiological and psychological aspects of *skin* are used in *Shiver* as both visual metaphors and sensory mechanisms. Visitors are encouraged to examine their agency in constructing boundaries between themselves and their immediate environment. The space between a visitor's body and the room's skin is excited by the swelling, shrinking and shifting water flows. These changes shift people's perceptions of the scale, moisture and heaviness of the installation space. The title of the piece, *Shiver*, refers to skin response to light touch, air movement or close proximity to another living being. As visitors walk around the room, the rivulets are programmed to move symbiotically along the walls. A non-verbal conversation emerges, and the room itself appears to be highly empathetic. My desire is for viewers to return that perceived empathy through their movement in the space. This haptic feedback loop creates a sense of physical intimacy, within a space that functions as if it is a sentient organism.

In the *Elemental Bodies* series, my premise is that the edge between body and space forms a fluctuating borderland that is always present. The viscera of the physical body is encased by skin, but the senses extend the border of the corporeal self. This boundary varies in accord with physiological, psychological and environmental changes. Skin shields our interior workings and makes them mysterious, but also acts as a profound mediator between our inner and outer world. *Shiver* is meant to heighten awareness of such negotiation.

My perspective on skin has been reinforced by studying its biological and structural functions. These are described and analyzed in non-clinical language in *The Body's Edge: Our Cultural Obsession with Skin*,

written by pathologist Marc Lappé. [2] He compares our common perceptions to biological reality: “Until recently,” he says:

“we have tended to think of the skin as...a watertight covering that enfolds ourselves and our organs and keeps them separate from the world out there. We visualize the skin in purely Euclidian terms, as a two-dimensional sheet that envelops us in a kind of perpetual Saran Wrap. ...In actuality...the skin is a highly convoluted, vulnerable, three-dimensional landscape. [It] has valleys, ridges, and folds, much as does the earth’s surface. And, like the earth, it is shot through with pores, holes and channels that greatly increase its surface area and make it anything but a smooth, two-dimensional surface.” [3]

Lappé continues:

“The skin is actually designed to permit a constant flow of insensible [unmeasurable] water percolating upward from its deeper layers. ...This water resistance but not waterproofness of the skin is due to the coexistence of two different pathways. ...These pathways take the form of molecular sieves that interpenetrate the skin much as wormholes pass through ancient wood. ...These channels are positioned underneath the skin like the honeycomb of a beehive. This structure provides tiny interstices where...slightly salty water constantly percolates upward to the skin surface through the underlying dermis, much as a plant receives replenishment from its roots.” [4]

In the collection of clinical essays, *Biophysical Properties of the Skin*, author J.R. Kanagy opens his chapter on water absorption with a declaration: “The relation between water and skin is one of the most important phenomena of life on this earth.” [5] He explains that most body water is bound in gels of connective tissue and cell bodies. “Water is, in a sense, skeletal in that the physical properties of...tendon, ligament, bone and the tough connective-tissue structures...are altered very appreciably by both increases and decreases in this content of bound water.” [6] In an essay on electrical properties of skin from the same book, Dr. Robert Edelberg writes: “In addition to its role in thermoregulation and water-balance, the skin is also a tactile sensory organ, and its mechanical characteristics greatly influence the nature of the neural pattern which occurs where it makes contact with an object.” [7]

While *Shiver* doesn’t schematically represent skin, its architectural presence and water interactivity invite comparison to these biological descriptions. Lappé, Kanagy and Edelberg’s observations reveal a framework for skin that is architectural in nature and intrinsically linked to water. In *Shiver*, the structural and sensing systems are two physically integrated layers located outside and inside the wall membrane. In concert, they offer an experience of *ourselves-in-space* and construct a loose representation of sensing. The beautiful, refreshing presence of water in *Shiver* reflects Lappé’s assertion that: “Our sense of psychic well-being is inextricably linked with our skin.” [8]

Edelberg’s statement regarding touch evokes the use of our hands, but our primary touching experience is through the skin as a whole, by far the largest organ in our body. Skin pushes against the exterior world, touching air or clothing at every single point on our surface. Our skin’s contact with space is critical to forming our experience of space. Skin enables us to gauge the size and ambiance of the environment. It reveals details of our location through temperature, humidity, electrical charge and air movement. Skin sensing is a major component of the intuition mechanism, and helps us predict interactions with other living beings through subtle perception of factors such as heat, tension, fear, conductivity and health. Together with the eye, skin allows us to comprehend our surroundings without directly using our hands to touch them. In addition, skin’s high degree of permeability causes us to be in constant interchange with our domain, contributing to metabolism, immunology, temperature regulation, absorption

and health. Skin is multi-purpose, resilient and interweaves us with our immediate environment. We meld with space. Our boundary is not an edge. It is an atmosphere.

My ideas about the role of space in human experience are further defined by architect and theorist Juhani Pallasmaa in his 1996 book, *Eyes of the Skin: Architecture and the Senses*. [9] Pallasmaa outlines an architectural history that is dominated by “ocular-centrism” and calls for design that is “multi-sensory” and “puts the body at the centre.” He places touch at the core of that mission. “Touch is the sensory mode that integrates our experience of the world with that of ourselves. “[M]y body remembers who I am and where I am located in the world.” [10] Citing noted anthropologist Ashley Montagu’s book, *Touching, The Human Significance of Skin* [11], Pallasmaa notes:

“All the senses, including vision, are extensions of the tactile sense; the senses are specialisations of skin tissue, and all sensory experiences are modes of touching and thus related to tactility. Our contact with the world takes place at the boundary line of the self through specialized parts of our enveloping membrane.”

He poetically compares sight and touch: “The eye is the organ of distance and separation, whereas touch is the sense of nearness, intimacy and affection. The eye surveys, controls and investigates, whereas touch approaches and caresses.” For Pallasmaa, “Architecture is the art of reconciliation between ourselves and the world, and this mediation takes place through the senses.” [12]

Shiver is meant to open the senses to the expanse of the room. As we move through physical space, our awareness wanders as we attune ourselves with touch, sound and sight. Electrical conductivity and heat radiate off the skin like an aura. Involuntarily, we exercise an innate ability to modulate our senses in order to become more responsive or more isolated from our immediate environment. We may self-protectively shut down our awareness – subconsciously, but with purpose - in order to avoid unpleasant sensations. Physiological and psychological pain are sometimes more feared than actually felt, and may provide us with a great deal of self-information, if we are willing to pay attention. Adding to our confusion about the value and need for sensation are recent commercial technologies, which encourage us to distrust our senses and rely on personal, electronic devices for presumed accuracy about the natural world. The mobile app preempts our skin’s natural ability to know that the weather is changing. We fill gaps of time by scrolling through our smart phones, fascinated by their responsiveness to touch while ignoring or discounting our own abilities to experience sensation through our skin.

For Pallasmaa, the room takes on sentience simply by its existence. “A work of art functions as another person, with whom one unconsciously converses. When confronting a work of art we project our emotions and feelings on to the work. A curious exchange takes place; we lend the work our emotions, whereas the work lends us its authority and aura. Eventually, we meet ourselves in the work.” [13]

For the construction of *Shiver*, it was important to me to contain the water phenomena within a room-sized space to amplify the relationship between a visitor’s skin and the wall membrane. A *room* is broadly defined in the dictionary as, “a space that can be occupied,” [14] and this applies to skin as much as to space. A room becomes the casing of your casing – containing, mirroring and doubling *all-of-you*. It has its own atmosphere, which determines what you will wear and permits or denies the effect of air movement on skin. The size and texture of a room defines your body language and the scale of your gestures. Its layout and furnishings dictate the extent of your impact by describing your range, movement, vocal magnitude and timbre. For most of us, the idea of *who-you-will-be-today* is created in rooms, as we navigate questions of social position, authority, formality and vulnerability.

Shiver was created to be a temple of compassion. It will not ignore or overlook you, but pours with sensation. One could argue that *Shiver* has the visual representation of the body flipped inside out. Images of guts, spine, nerve-endings and muscle are depicted by the circuitry, wiring, valves and exoskeleton of the room. Inside, the clean, smooth walls create an impression of the skin surface. This delineation between the convoluted outside and minimalist inside of the room is meant to separate *structure* from *experience*. Exterior technology evokes biology, but also references psychological filters such as memory, presupposition and wishful thinking – mechanisms we construct to mediate our experience of the world. The spare, monochromatic interior allows for a meditation on pure biological sensation without context, just as the water flows create their serpentine forms without obvious topography.

Although technology in *Shiver* is visible, it remains mysterious, and one's understanding of personal agency becomes slippery. The room's reactions to viewer movement can sometimes be anticipated, but at other times may frustrate or surprise. While many interactive artworks use a mirroring strategy to form the relationship between the viewer and the work, *Shiver* is somewhat less predictable. Leading, following and joining are additional tactics for engaging with this work. The level of intimacy with the room is akin to that shared with parents, lovers, close friends and self. You have to work, as with your human intimates, to comprehend the messages passing back and forth. This dyadic relationship with the visitor may eventually lead to a perception that the room is being sneaky, teasing or flirtatious. The water flows on the wall membrane express a feeling of being *turned on*, wet and shivering in anticipation. [15] The sturdy architectural presence of the room softens, and you become conscious of the physical volume of your body and the space within the room. Ultimately, you experience a perception that the room has a consciousness of its own. Comments from visitors to *Shiver* provide evidence that my intentions are realized: "It taught me a valuable lesson about slowing down and listening," "It has secrets, some it will share, some it won't" and "It is like foreplay. You try one thing and if that doesn't work, you have to try something else."

Organic elements in the four works planned for the *Elemental Bodies* series include water, air movement, heat, magnetism and tingling. Each element has a distinct way of engaging the body surface, activating the senses, bringing the body into direct relationship with its environment, and to the forefront of consciousness. The connection between our inner and outer ecosystems is made palpable. Lappé says: "In a strange way, we identify our skin with our innermost selves." [16] The works in "Elemental Bodies" restate the value of skin as a sensor that gauges conditions and acts as a harbinger for intuitive knowing.

THE MUSICAL SCORE: THE SYSTEM AND THE INTERPRETER

Thor Magnusson

This paper introduces live coding as a new path in the evolution of the musical score. Whilst being the perfect vehicle for the performance of algorithmic music, it also transforms the compositional process itself into a live event, where play and generativity become essential. Live coding is presented as a highly technologized artistic practice, often embracing graphical elements and language syntaxes foreign to standard programming languages.

It is a fact that in the evolution of instrumental music the performing musician has been condemned more and more to converting increasingly complicated scores into tones. Musicians became a sort of machine substitute, and finally there no longer remained any room for “free decision”, for interpretation in the best sense of the word.[10]

Opening the Musical Score

The musical score has always been in constant evolution. The score implements the idea of encoding music such that it can be stored, disseminated, and performed at later occasions. Initially the score served as recording device, but it quickly became a tool for thinking music at a more complex level, serving as an extension of the composer’s cognitive capacity. The idea of looking at the score as a technology that has had dramatic effects on music corroborates with the findings of scholars who study the difference between oral and literal cultures. [9] Concomitantly, any history of the musical score will demonstrate the increase of sophistication in the control composers assert over performers. Whereas in early medieval and renaissance scores large parts of the music were improvisations, the 20th century score became highly specific, where explicit and increasingly nuanced instructions were given about pitch, loudness, rhythm and articulation.

In the late 19th century, systems using loom punch cards in order to encode music for machine playback (e.g., in pianolas and other musical automata) became popular and this development of automatic music took a leap in the 20th century with the commercial use of audio recording. As a response, and in an opposing spirit to this machine representation of music, composers began exploring new systems for composition, where graphical scores and textual instructions became more prominent. Related to these developments, the score was increasingly understood as describing gestural information for the performer, rather than being descriptions of pitch organised in time. The works composed in the first half of the 20th century for prepared piano, e.g., Villa-Lobos’s *Chorus no. 8* (1925) or John Cage’s *Bacchanale* (1940), are good examples of this shift.

A further evolution took place in the 20th century’s conception of the musical score. With works such as Stockhausen’s *Plus-Minus* (1963), Pouissieur’s *Scambi* (1957), or Cardew’s *Treatise* (1963-67), we gain the notion of what Umberto Eco calls the “open work” and the “work in movement”, where the form of the composition itself “consists of unplanned or physically incomplete structural units” [5]. In these pieces performers are given a chance to improvise and interpret the score, such that the work has much wider expressive scope. In the words of Stockhausen from the same text as the initial quote:

But fit is noteworthy that the same composers who had called electronic music to life, *parallel* to this work in the years since 1956-57, published compositions which present the performing musician with a completely new responsibility. [...] in this new instrumental music the performer is granted fields for free, spontaneous decisions, to which machines are not amenable. [10]

The motive of this article is not to analyse how machines have evolved since Stockhausen wrote this text. What is of interest is how, in Eco’s definition of the open work, it is clear that the openness under discussion is not a passive interpretation of the piece, but rather an active engagement where the structural elements of the work are manipulated by the performer or the listener. The open work is therefore a system that enables the interpreter to actively engage with the score itself, reinterpret it and appropriate it to the context in which it is performed. In a way, a feedback loop has been introduced between

the performer and the score; an idea that (strongly amplified) becomes a central feature of live coding performances.

The musical score is a system of instructions: abstractions that represent musical gestures for the interpreter of the score. From this perspective it does not differ much from the instructions inscribed in software that generates music. In fact, there is no intrinsic difference in writing music in the traditional staff notation or as software code. The question is rather what kind of interpreter the music is written for and what logic is applied for non-deterministic decisions, if those are used in the piece. As a matter of fact, the computer can easily read staff notation and the human instrumentalist can perform music by reading computer code. This paper will look further at the question of the interpreter, but also how live coding systems, particularly as they emphasise the performance elements of musical coding, can be seen as musical compositions in their own right.

Interpreting Code: The Appeal of Software Art

In the last decade software art has become a prominent field where musicians, designers, programmers, and artists of various art forms explore the potential of the computer to execute their art. Traditionally, software art has focused both on the formal structure of code, following the modernist tradition, and engaged with society and politics where software serves as a cultural critique. [4] Since its inception, software art has shown that writing code can be just as gratifying artistically as painting on canvas or dancing on stage (see www.runme.org). Indeed, the ubiquity of computational algorithms in our daily life has given birth to a new research field called software studies, which engages with the role of software from a cultural theoretical perspective. [6] Software art might be a subordinate field of this research programme, but the question remains if the category of software art is merely a transitional one, due to the omnipresence of software in all types of art and the general realisation by artists that generative features can add value to their work.

Artists have become attracted to software. In the art after Fluxus – which emphasised process, audience participation, and performance as algorithmic instructions – practitioners have become intrigued by the potential of delegating some of their creative decisions to algorithmic processes, which can be based on, for example, stochastic models, environmental variables (such as weather, animal behaviour or human interaction), or artificial intelligence and artificial life. Computational creativity, the idea of writing systems that produce novel solutions to ‘problems’ such as creating art, has proven appealing. [2] In this field, various generative music systems have been created with impressive results, and in the world of painting one might consider the work of Harold Cohen, with his robotic painter Aaron, as a strong candidate (<http://crca.ucsd.edu/~hcohen/>). More recently, this idea of creative delegation to non-human processes is strongly explored in bio-art where biological systems are used as parts of the aesthetic process that create, or indeed *are*, the artwork. (see for example the work of Andy Gracie at www.hostprods.com or the activities of Symbiotica at www.symbiotica.uwa.edu.au)

Although software art is often exhibited in galleries, its natural habitat is on the internet where software can run in the user’s browser or be downloaded as standalone applications. Much software art retrieves data from online servers, strengthening the dependency on the networked grid and relating strongly to another strand of computer based artistic practice called net art. [1] The software is an artistic product, like a book or a film, to be enjoyed and interacted with by the user. It is a system of abstractions that can present any artistic media, but at the core is the artistic expression whose *material* can be any medium, multimedia or code itself, but whose *form* is necessarily encoded as software code. Often the

software is of a generative nature, rendering new versions of the piece, each time it is executed. Here the software operates as a score or a script that is interpreted by the machine. Indeed, in many programming languages, the primary system that executes the code is called the *interpreter*, resonating with how musical scores can be seen as abstract instructions performed by the human interpreter, the instrumentalist.

Live Coding as Delegation of Intention

Musical live coding, [3] [11] arguably a subordinate field of software art, is different in this sense as it requires the human to perform the work. In order to be able to write code as a performance act, the programming language has to be at a level allowing the live coder to quickly write the musical algorithms in an improvisational way. Few audience members would endure the manner in which compiled languages are written, for example. This has resulted in a practice where the live coder “composes” a system outlining beforehand the musical constraints. This, in many ways, is akin to composing music, in particular the 20th century open work scores (as analysed by Eco) that typically break out of traditional notation, for example by using graphical encodings. Creating a live coding system can therefore be seen as a compositional activity although, of course, the boundary between a composition and an instrument are never clear in computer music.

In live coding, the system can be seen as carrying out the role of the musical score, performed by the live coder. This performance is based on a strong practice of engaging with the score by writing instructions for the *language* interpreter. We therefore have a twofold layer of interpreting, one where the human interprets the piece (which here is seen as the live coding language itself) and another where the language interpreter interprets the human performance. Between the live coding system and the interpretation of the computer, a space is created in which the live coder improvises, composing in real-time through writing code, in a style of performance that requires a journey back to the baroque period if we want to find a strong parallel (an activity then called *extemporisation*).

From this perspective, one can frame the live coder as a delegator akin to the artificial life or biological systems mentioned above. If the live coding system is seen as a musical piece itself, the performing live coder becomes the interpreter of that piece, rendering variations of its generative potential.

It should be noted that live coding does not have to involve computers at all. Nick Collins has, for example, done various experiments with live coding of human performances where he has worked with choreographers, dancers and music improvisers in writing instructions that can be algorithmically executed. Collins defines live coding as an activity that necessarily includes a reflexive element, stating that the “more profound live coding must confront the running algorithm.” [3] If we accept this strong definition of live coding – and Collis does acknowledge that many live coding performances do not live up to this promise – it is clear that live coding introduces a new form in musical practice that actually requires performers to exercise their free will during performance and rewrite the score (the running algorithm) ad hoc.

Three Live Coding Systems

The live coding systems I have in mind in this article are typically custom made and unique expressions of their authors. Although one can live code with any interpreted language, such as Python or Scheme,

the typical live coding system is built *upon* such a language, creating a higher-level abstraction that effectively becomes the scope in which the performer works. The questions of affordances and constraints in creative systems become pertinent here, since the constraints of a system often yield strongly creative output. [8]

Alex McLean is currently working on a live coding system called Texture where one writes textual instructions for the interpreter, but this text is of spatial nature where location and proximity define the meaning of the words and their functions within the main synthesis or musical graph. The aesthetics of this programming language reminds us of concrete poetry, whereas the functionality resembles a mixture of Pure Data and SuperCollider, which are both audio programming languages used in live coding. The environment is impregnated with common computer music terms of oscillators and filters, and mathematical functions are presented with common symbols in addition to lines that define the relationships between the signal graph objects.

My own *ixi lang* is a highly constraint system built on top of SuperCollider. The idea here is to create a performance framework enabling me to write quick code that results in the formation in a musical piece in few seconds. The more I play with this system, the more I get the feeling that the system itself is a musical score that I play differently each time I perform it. If *ixi lang* is a piece of work in itself, a performance using it becomes like a variation of its expressive potential. I should note that, unlike Adrian Ward with his Auto Illustrator software art piece (www.signwave.com), I do not consider myself a co-author of the music made with *ixi lang*. As a musical score, the *ixi lang* exist at a meta-level above direct instructions. The software was released two years ago and it has been very inspiring to see how other people use the system. Surveys, user testing and interviews have confirmed that users of this system enjoy the inbuilt constraints and report that this can yield creative results. [7]

Nick Collins, a long time live coder, has recently created a live coding app for the iOS operating system. The application has a simple user interface, consisting of the letters in the TOPLAP (an organisation concerned with live coding - see toplap.org) name that can be dragged around the screen to program a virtual machine for sound synthesis. The patterns of these letters become the instruction set for the interpreter to generate audio, typically a quite noisy but interesting output. This app is a good example of an open work in the form of a software, presented as a live coding system where the end-user performs the piece, in a manner envisioned by Pousseur when he composed his work *Scambi*. This work also shows the potential of creating live coding systems aimed for distribution and active interpretation by the performer/listener.

It has to be noted though that live coding systems are very diverse, from high level languages to lower level systems, from graphical representation of code to textual, and using diverse types of input devices, although the computer keyboard might be the most common device. The definition in this paper of live coding systems presented as types of musical scores might be less appropriate for more general audio programming frameworks like Impromptu, ChucK or SuperCollider. The three systems discussed in this article should be seen as open work scores existing at the meta-level, thus giving the performer a wide scope for expressive freedom.

Conclusion

This article has focused on live coding systems as a development in the history of the musical score. The live coder has to practise the important skills, but the system enables the performance to be highly improvisational, in ways that relate back to medieval and baroque music, but contrary to how the late 19th and 20th century music tradition formalised the musical score and performance (with few exceptions). The paper has drawn these parallels with older music and systems of representing it, but also contextualised live coding as a practice that relates to new types of musical scores originating from the mid 20th century. Additionally, the technological framing of these types of works, strongly engaging with the history of machine music and its encodings, afford new ways of relating to the performer, the listener and the social setting in which musical pieces are presented. Live coding is therefore an offspring of two strong traditions involving the formalisation and encoding of music, often for machine realisation, on the one hand, and the open work resisting traditional forms of encoding, on the other.

Generative (or algorithmic) music is currently undergoing renaissance with novel live coding practices and explorations of algorithms as part of the digital musical instrument design. There is wider understanding of the fact that when our media become processor based, we are in an ideal position to write non-linear scores for new instruments that can contain generative algorithms as core of their sound engine. The days are gone when music has to be encoded or recorded onto linear formats. When the mp3 has been superseded by the app, prolific opportunities present themselves for writing novel music, including musical scores.

SYMPTOMATIC ARCHITECTURES. SPATIAL ASPECTS OF DIGITAL EXPERIENCE.

Angeliki Malakasioti & Spiros Papadopoulos

The research attempts to introduce a series of conceptual analogies that describe the spatial qualities of cyberspace through the mental state of its users. This happens through the introduction of some altered kinds of architectures; some architectonic scenarios that are referred as ‘symptomatic’ architectures, since they are discovered through a process of diagnosis of the mental and psychological experiences of the internet user.

Call It Space

When, in the course of a digital era, the term ‘cyberspace’ is infiltrated through continuous technological scenarios, space is no longer seen as the mere background of events. It becomes the foreground of every single human experience of ubiquitous digitality – an aspect of ‘life processing’ mechanism inherent in each computer generated/mediated environment.

Space, not in its physicality – materiality is attempted to be traversed – but in its contingent aspects of its abstract forms; call it imaginary – call it mental – call it digital – call it space born out of noetic ingredients mixed together in a synthetic recipe of personal, electronic experience; experiential referents of oneself’s head-on collisions with cyberspatial promises – or premises – born out of contemporary reality.

And then, experience is binary distilled, imagination blown up and space germinated. Spatial sprouting is taking place in the totality of personal mental functions, in the unnamable morphing of thoughts, actions and translations. All amalgamated into the digital environment as multiple shades of sole inhabitations; inhabitations of divergent personas, disordered players, inertially echoic avatars and telepresent ‘switch-on switch-off’ lives.

Symptoms Elicited

These situations, these parts-of-the-whole, as bi(y)t(e)s of information, either code generated or humanely derivative, constitute the symptoms of digital experience. Symptoms to be felt, lived and catapulted into the process of intimate space translation.

Spatial experience is a symptom – what is given to the ‘observer,’ what is manifested and constituted as an essential phenomenon. Its principles are not ones of sovereignty and termination, since its nature refers to the single, but not absolute, formation of a disorder abstract. Symptom is a piece of an incomplete pathology, an unfulfilled actualization of a solid state. It constitutes an inseparable relationship, “a primary stratum of the indissociably signifier and signified.” [1] This connection between ‘symptom and disorder,’ as the diptych ‘experience and digital space,’ indicates the signaling and translation of what exists, but not the absolute depiction. Digital experience is like a symptom, a mental phenomenon outlining a kind of space which will become uniquely personal and noetically invented.

Improvising Pathologies

Digital space evokes fragmentation and fluidity, thus, fragments constitute the compositional elements of contemporary, cyberspatial endeavor. Mental qualities become the playground field of digital experience, due to the challenging immateriality of space. Therefore, space is correspondingly constructed parallel to the composition of individual mental states – states altered, distorted, and inspiringly disrupted, as if parts of a dis-incriminated pathology.

Thus, the symptom is not the pathology itself, in the same way that “the map is not the territory.” [2] Symptom is a form of mental representation of an event, a phenomenon inherent in a unique spatial narrative. Only a set of symptoms can potentially constitute a disorder, therefore digital experience can be regarded as a natural and dynamic, mental state.

CorpoRealize

Each symptomatic indicator is a signifying spatial phenomenon. It is enticed by multiple scenarios, brought to life, and then, is manifested as a phenomenon waiting to be ‘realized.’ But every symptom is a form of space realization, which in terms of digital immateriality can become the corpus of the disembodied mind; or the notion of the absent body that is re-present-ed through this altered state of consciousness. “In every symptom, there is, so to speak, the whisper of a direction, the hint of a path;” [3] this ‘direction driven’ report composes a kind of diagnostic awareness, that discloses a mentally constructed space; a fragmented, and rather demystified, space – a symptomatic architecture.

Dis + Sociare

The digital observer must invent a new, altered diagnostic tool [4] – a handbook of the mental, symptom-like, digital phenomena. Symptoms are juxtaposed to self scenarios in digital environments, both filtered through spatiality issues and architectural derivatives.

The most complex and multifaceted view of dissociation refers to the act of separating, breaking, disuniting or decomposing; or put simply, the act of removing from association. Digital inhabitation is direct referent of identity formation or role-playing conditions. A bunch of dislocated selves are invented and acted out, transferring characteristics of, both existent and non-existent, personalities. Dissociative space is generated and thus, it is considered on the basis of experience that includes alterations, disruptions or, sometimes, mutations and breakdowns of the individual’s structures concerning memory, perception or consciousness.

This space is discontinuous and divergent – all of these qualities placed as experiential composites of what can be described as an “ocean of leaky selves.” [5] Contrary to the deviant sense of ‘leakage’ and the diffusing quality of the ‘ocean,’ contemporary identity proves a surprisingly congruous outline; all these inconsistencies of self decentralizations and role constructions can formulate the delineation of its whole image, a portrait made of a plethora of selves merged into one and sole (id)entity.

Verge on

Digital encounters include liminality; and liminal encounters include a decision of transference or an unconscious act. Personal sense of flow is sometimes affected by disruptions of perception, that verge on the limits of differentiated states. A whole new space full of inertial qualities is constructed and then, is offered for inhabitation and interaction; a space that lies between two states of consciousness or two ways of existence. Inhabiting a threshold is an essential element of digital experience; a threshold as a bipolar mechanism – one that leaves the biological body behind, while moving towards an immaterial digital environment, or one of departure, while ‘logging out’ towards the physical world. In both ends, experiential fragments are transferred and a threshold mechanism is manifested in the two directions. Inertia acts as a spatial metaphor, and outlines issues of resistant, direction-shifted and perpetually fluctuating space.

Echopraxia

Digital space does not have a shadow, but digital actions do. For every digital event there is the respective cyberspatial echo born out of the individual’s, volitional or not, act; an act, like an echoic ‘praxis,’ resembling the ideo-verbal, psychotic symptom of ‘echopraxia.’ [6] This kind of continuously constructed echoic space consists of all the cybernetic material that constitutes what is called ‘digital shadow’ or ‘footprint’ – the totality of information that is produced and stored in digital space.

Every user is estimated to produce a unique ‘history,’ namely incredible amounts of informational shadow by every single movement in cyberspace. This shadow, just like a kind of electronic dust, gathers up and follows oneself, resembling a ‘hypermnesia disordered’ state – an extended and unusual aggregation of mental elements. An unconscious sum of mental constructions which, combined with the conscious ones (dissociated spaces, de-centered and multi-personal environments, liminal spaces with inertial qualities), brings one back to the importance of the invented self scenarios as spatial mechanisms. Since space is experienced through the individual’s mental phenomena, symptomatic architecture is the erection of structures that either interpret or, conversely, provoke new self scenarios.

Tell the Tale

“One describes a tale best by telling the tale.” [7] If symptomatic architecture is considered as a dynamic diagnostic process of the multiple digital scenarios being experienced, then it can consist of a mixture of observations, evaluations and interpretations that give a hint about space – both as narrative and narrator. It is not the accuracy or solidity of a set of qualities that best describes digital space but the process of ‘telling the story’ – of representing personal experience through symptomatic architectures that tell a tale – one without a nameable ending.

MY META IS YOUR DATA

Nicolas Malevé

This paper examines different data practices, taking examples from “social” networks, activist collectives and open source communities and looks at the recent decisions taken by major forums such as the EU Council, various national parliaments and ACTA negotiators. It analyzes how these decisions threaten a wide variety of spontaneous as well as organized collaborations, social interactions, and cultural developments.

The following essay is a result of my experiences with Constant, a Belgian-based cultural association working with various media since 1997. For the past decade, we have been exploring the potential of the culture of sharing, particularly in the context of artistic, creative and cultural content. In early 2000, we became interested in the way online services provided an infrastructure for sharing and collective production. Later branded as Web 2.0, these services helped popularise Creative Commons licenses. A striking example of this attitude was articulated in the early ‘terms of use’ of Flickr, a photo sharing service created in 2004 by the startup Ludicorp. It stated: “We encourage users to contribute their creations to the public domain or consider licensing their creations under less draconian terms than have become standards in most jurisdictions [...] Ludicorp undertakes to obey all relevant copyright laws however misguided we may all judge them to be.” [1] Though this initial statement sounded promising, within a few years the rhetoric had completely changed. Big players bought up small platforms in order to expand their services and increase the value of their portfolios. Google bought Blogger and YouTube; Yahoo bought Flickr. Since 2005, the tone has changed dramatically. Now, upon accessing Flickr’s copyright policy, we find the standard Yahoo copyright terms. The once-critical perspective has long since been replaced by copyright policies focused on avoiding infringements. Rather than encouraging re-use, policies are now aimed at protection, restriction and enforcement. This shift, and its consequences, should not be underestimated. This is the basis of my reflection on contexts of interpretation and why they matter.

User Data and Contexts of Interpretation

On first sight, most services seem to have kept their identity. Browsing Blogger, YouTube and Flickr, each feels like a distinct entity. But the company owning the platform actually controls the policies, and monitors data traffic across the variety of platforms they own. Through this access to user data, the companies learn from user habits, tastes, relationships, and use this knowledge to provide marketing specialists and advertisers with precise statistics and personal profile data. In essence, the function of the Web 2.0 platforms is to transform the mess of social relationships into formalised and comprehensible behaviours. As relational data is of strategic importance for creating valuable user profiles, every single action expressing these connections must be captured. Therefore, the platforms require that you state your preferences and affinities. They constantly provide you with formats, interfaces, and icons with which to express social connections. It is not enough to drop a note or a comment, you have to ‘login to like this image,’ ‘accept a friend request,’ or confirm which people you wish to disclose your content to.

This parasitic formalism occurs at every moment of digital socialisation and creates a feeling of awkwardness: friends on Facebook may only be acquaintances, but the interface forces you to either categorise them as friends, or else refuse to engage with them at all. Or consider the peculiarity of being

asked to identify familiar people in a picture in order to log in to our account. All these awkward requests can be understood as symptoms of the fact that the context of interpretation is outside of our reach. We are asked to express our likes and dislikes in such a fashion, only because the system requires this kind of structure in order to process the information. How it actually works, we don't know; what we do know is that when we surrender to its ambiguity, the system rewards us. When somebody accepts us as a 'friend', we can access their content. Identifying a half-drunk classmate in a blurred photograph allows us to log in to our account.

But, as Andrew Goffey and Matthew Fuller explained in their lecture "From Grey Eminence to Grey Immanence: The Ambiguities of Evil Media," "Crucially, systemic ambiguity is as much about the production as it is about the deciphering of signs. Becoming able to read the shifting balance and distribution of forces in fluctuating patterns of uncertain signs is one thing. Being able to produce such signs, to turn them to your advantage, is another." [2] Web 2.0 capitalises on this systemic ambiguity.

Every single mouse click connecting A to B is thus captured, logged and processed. Since this information is crucial, it needs constant verification – it needs the user's cooperation and care. As a user of social platform and Web 2.0 services, you are put to work. Not only do you produce content and connections, you also have to control the quality of the circulating data. You rate, recommend and report. And the interface rates you back: your performances are public. One can see how many comments and 'likes' you have received, how many people have played your video. You have 500 'friends,' 5 'badges,' and 3 'followers' while you yourself 'follow' 100 people, and 'you haven't added any tip near Vigo, yet.'

For their online presence, many activist collectives, though critical of commercial media, use a combination of open-source software and social network add-ons. They are often ambivalent about what to keep under their own control, and what to delegate to online services. Many forms of delegation exist: 'follow us on Twitter,' 'like' this article, 'contact us at ...@gmail.com'. As reputation systems are extremely difficult to (re)produce without massive investments, these collectives 'outsource' such systems to social networks. The same is true for any functionalities requiring real-time management of communication with a large user base, connections with cell phones, or specialised features such as maps or videos. The online presence of such groups can be pictured as a thin layer managed by the group itself, superimposed on data from external services: connecting systems, but without any control of how the data is managed and interpreted.

During the student demonstrations that took place in England this year, the British police used a technique called kettling. Kettling, as Wikipedia defines it, is "a police tactic for the management of large crowds during demonstrations or protests. It involves the formation of large cordons of police officers who then move to contain a crowd within a limited area. Protesters are left only one choice of exit, determined by the police, or are completely prevented from leaving. In some cases protesters are reported to have been denied access to food, water and toilet facilities for a long period." [3]

A group of students and volunteers teamed up to create Sukey, an application informing protesters of the movements of the police, and directions protesters should take in order to avoid being trapped in a cordon. The information is transferred in real time via a web platform to and from mobile phones, and is provided by protesters, observers and people monitoring the news. Since many people rely on the authenticity of this information, identification of sources is crucial.

Sukey searches for messages on Facebook, Twitter, Tumblr and other social networks using the hashtag #Sukey. The results are then filtered using what one of the programmers calls “a kind of algorithmic reputation management.” The use of Sukey has proved very useful for protesters who successfully used it to escape kettling. But it has also raised many questions regarding the way it relies on external platforms to establish the reliability and trustworthiness of its sources, in a context where trust is essential. It tapped into the social networks’ power to aggregate and spread information and map out relationships, and used this power to distribute strategic information to protesters. But in doing so, it also fed the data-hungry machines of social networks with sensitive information about protesters and their circles of friends.

Using the Web 2.0 to outsource the real-time management of information and the quantification of trust, means relying on parties that have no interest in protecting user information from prying eyes, and are not committed to systematic encryption or erasing logs, but instead run systems designed to eavesdrop and record every possible element of relationality. Past experience has shown how their loyalty, more than often than not, lies with the powers that be. How long before the street corralling gives place to the digital cordon?

The example of Sukey is important on more than one level. It questions how activist applications relying on connections to social networks can preserve their autonomy and control the flow of data. It also emphasises the importance of legislation regulating how and when authorities may access information gathered by Web 2.0 platforms.

Let us now move on, from the general context of social media to the subject of the harmonisation of legal frameworks which regulate the way these media (and their corporate governance) operate within European law.

Parallel to the development of the Web 2.0, an impressive number of international agreements, directives, legislative bills and draft recommendations have landed on the desks of decision-makers in the USA and Europe (at both EU and national levels). The legal framework regulating the relationship between authorities and user data is currently undergoing a process of harmonisation. Brandishing the spectre of piracy, these agreements invariably emphasise the same point: strengthening cooperation between service providers and the authorities. The negotiators of the Anti-Counterfeiting Trade Agreement wish to promote what they euphemistically refer to as a “cooperation between service providers and right holders to address relevant infringements in the digital environment.” [4] The experts consulted by the European Commission provide a more concrete explanation of this cooperation. They consider the service providers in a favourable position to not only “contribute to prevent” but also “terminate” infringements, [5] and therefore suggest to the Commission to “involve them [the service providers] more closely.” [6] The Trans-Pacific Trade Agreement proposes that its signatories create “legal incentives” to ensure service providers’ cooperation. [7] Clearly, adjusting legal texts in order to promote cooperation between governments and service providers is a recurring theme, meaning service providers are expected to disclose user data to authorities, to assist in monitoring user behaviour, and even to pro-actively take appropriate punitive actions.

But who exactly are these ‘service providers’? The definition of the term varies from one text to another. Service providers can either be companies providing access to the Internet (also known as access providers) or companies providing services on the Internet. This rather broad definition can be explained in a historical perspective. Access providers and service providers both followed the same evolutionary path: an assortment of small startup companies, most of which were later bought up by larger ones. As

Kleiner and Wyrick strikingly formulate it in their essay “InfoEnclosure 2.0”: “The mission of Internet Investment Boom 1.0 was to destroy the independent service provider and put large, well financed, corporations back in the driving seat. The mission of Web 2.0 is to destroy the P2P aspect of the Internet. To make you, your computer, and your Internet connection dependent on connecting to a centralized service that controls your ability to communicate.” [8] By reducing the number of access providers and online services to a few big players, a powerful movement of concentration and homogenisation is taking place. The access providers determine how one can access digital communication; the online services increasingly define the framework in which content, contacts and dialogue take place. For governments, gaining access to these central reservoirs of information about their citizens’ behaviour becomes a strategic issue. And both access providers and service providers can provide the same ‘service’: making available their concentrated silos of data.

Currently, although service providers are regularly mentioned, access providers still remain the preferred candidate for this kind of cooperation, as they have complete access to data traffic. But recording, analysing and filtering data traffic costs money. Governments don’t have the money to finance such an infrastructure. And so a new scenario is beginning to take shape, with more clearly defined roles for all parties involved.

Service providers monitor and filter user traffic and cooperate intensively and pre-emptively in the struggle against copyright infringers and criminals, going above and beyond their traditional role of neutral intermediaries. This requires setting up a costly infrastructure, which can then be used by the service providers to allow different levels of access according to the nature of the content being transferred. Because the service providers have concentrated users’ attention and interaction into a small number of specific channels, the providers can strike deals with the services: users downloading mp3s from the iTunes Store enjoy full bandwidth, users downloading the same mp3s from Jamendo are allowed only downgraded access. The infrastructure built for surveillance can thus be recycled in order to develop a commercial model of bandwidth discrimination, abandoning the tradition of net neutrality.

Although some elements of this scenario are currently being tested in France, the United Kingdom and the United States, it still clashes with existing competition policies. Recently, Neelie Kroes, European Commission Vice-President for the Digital Agenda, voiced some very strong rhetoric against such traffic discrimination: “Mark my words: if measures to enhance competition are not enough to bring Internet providers to offer real consumer choice, I am ready to prohibit the blocking of lawful services or applications. It’s not OK for Skype and other such services to be throttled. That is anti-competitive. It’s not OK to rip off consumers on connection speeds.” [9] But as she herself needs the cooperation of access providers to finance broadband access (around €200 billion) for European citizens, will she be able to refuse them such a return on their investment? Since the future development of the digital economy depends on large investments, how long can we rely on competition policies to defend net neutrality?

To summarize: I have shown how the commercial scheme of Web 2.0 was built on the exploitation of user data, and how a collusion of interests between access providers and service providers could bring about a discrimination of access. The concentration of user information in Web 2.0 databases, and the monitoring of traffic by access providers, creates an enormous reservoir of data on citizens’ behaviour. Collection of user data is defined by the terms of use of web platforms, and government access to the information collected is defined by legal frameworks and international agreements which are constantly being developed and refined. The legislation currently under way, and the social networks’ terms of use, both demonstrate a similar attitude toward the gathering of user data: they disregard the users’ ability

to discuss, interpret and change this data. In these contexts, user data is not seen as an area for cooperation, and the context in which it is interpreted is deliberately kept out of the users' reach. Furthermore, the very process by which this data is stored and modified remains opaque as well as unilateral. At this point, we should consider the OpenStreetMap (OSM) project, which deals more intelligently with user data, and provides a wonderful example of how terms of use and legal decisions can be taken collectively by users; how a context of interpretation can be designed and maintained by a community.

In short, OSM is a Wikipedia for maps. Users upload geolocated information (GPS traces) to a server; they can then edit, clean up and enhance this information, before it is used to produce online maps. The site's database can be downloaded to create 'mirror' sites or geolocate services, or any other project requiring geodata. At various levels, the OSM project shows a clearly different approach compared to Web 2.0 data practices. Whereas Web 2.0 services provide users with an interface that conceals metadata and logged behaviour, OSM is proactively 'open' about its use of user data. The OSM experience starts by learning to think differently about the GPS device. Rather than merely follow its instructions, apprentice cartographers are asked to focus on how the device graphically renders their GPS trace and logs their itineraries. These logs can be uploaded to the project's database, and further processed to indicate roads, buildings, rivers, etc. Whereas recent legal developments in this area have been controversial and non-transparent, in OSM the user community establishes its own rules through discussion and consensus.

An important legal question recently arose, which provided an excellent insight into the dynamics of this user community. A few years after OSM was launched, participants realised that the license under which they were distributing the data included in the maps was not legally valid: geographical data does not fall under the scope of free licenses which protect 'original' creations such as literary works. 'Objective' information, such as geographical coordinates, falls into another legal category in many legislations. The OSM foundation, which facilitates the operation of the project, set up a process of consultation (lasting several months) with participants including legal specialists who volunteered their services. The goal was to redefine the terms of use in such a way that everyone can simply use the OSM data, but that users are required to add to the OSM database any corrections, additions or other modifications they make to the data. It was interesting to observe how participants convinced each other, in online and offline discussions, of the importance of protecting the open-source nature of the software, and preventing their common effort from being distorted while still keeping it open; and how they accepted to formalise their participation somewhat, in order to safeguard the fundamental motives behind their participation. This type of discussion demonstrates once again how anything considered as 'public' is subject to a constant process of re-negotiation.

What these examples show, is that there is no inevitable fate forcing us to accept that the context of interpretation of the data we produce using digital technologies should be kept out of our reach. The OSM project demonstrates that social dynamics and dialogue can produce comprehensive agreements on how to collectively share data, and how to take the necessary legal decisions collectively. It shows the power of open platforms and the difference we can make by being actively engaged in creating and maintaining a context of interpretation.

OSM is, although remarkable, by no means an isolated project in terms of its philosophy and development. Today we need strategies for making collective practices of data care a part of the legal dialogue. But more than ever, we need to experiment with collective forms of management, in which the administration of user data is not synonymous with policing or profiling. We can begin with simple steps, such as

running a group's blog or imagining new scenarios for exchanging data, before moving on to more complex undertakings such as installing a web server, exploring new platforms and different policies, taking part in their design, promoting them, and participating in their maintenance. The task is huge, but it can be broken down into smaller individual actions. What we will gain in freedom and knowledge, we will have to pay for with time and/or money. But if we wish to gain access to the contexts of interpretation, free is better than 'free'.

INTRAINER SOCIALITE: EMOTICON JACKET FOR SOCIAL INTERACTION

Kristin Stransky Mallinger

intraInter socialite is a wearable computing experience that investigates the loss of intonation and body language that occurs at the intersection of computers and textual communication. Emoticons, an attempt to express emotional nuances in the virtual realm, are used to subtitle interaction that occurs in the physical realm. This is achieved through force sensors that display emoticons on a jacket with a LCD screen.

Kristin Stransky Mallinger, intraInter socialite, 2011, Emoticon jacket with LCD screen, LilyPad Arduino board and force sensors (artwork and photography © 2011 Kristin Stransky Mallinger).

Emoticons construct a variable language meant to convey emotions, physical and mental states in a textual context. An emoticon consists of various punctuation and letters from the Latin alphabet to create perpendicularly oriented graphics. Although it creates a graphical language and can be universally understood, it still allows for user and virtual service interpretation. Some services — IM and email clients — convert the text to a graphic, which it is perceived to represent. These graphics are an inconsistent interpretation and vary according to the client.

Two or more users that are using messaging clients can use different clients within the same conversation and get different graphics for the same text. Users can also include additional or fewer characters than what the service recognizes, which will effect whether the client converts the text to a graphical representation or not. For example, :) would in most cases be perceived as a smile graphically, connoting a happy emotion. However, :-) may be the text recognized by the client to produce a graphic. Textual representations and their varied graphical outcomes can change the interpretation of the message and emotion. Some users may feel that :-) is a more effective smile, whereas some would argue that :) or the graphics produced are more effective.

The inconsistencies in representation of emotions can lead to some confusion. Another way in which emoticons can lead to confusion are when the emoticon is not supported by a client or is not common in a user's repertoire. When an emoticon emerges, the service is often lagging in converting its use to an agreed upon graphical interpretation. Additionally, there are many different emoticons being created to fill the user's need for emotional expression. Both users may not be proficient in a particular emoticon's connotation and this may lead to an emotional or contextual disconnect in the conversation.

Just as a person's physical cues can be misinterpreted by those interacting, emoticons and their inconsistencies can lead to misinterpretation and confusion. They can also contribute to the lexical direction and enhance a conversation. [1] Emoticons provide non-verbal indicators of emotional cues that can be lost in text-based interaction, but also reinforce physical indicators if introduced to a face-to-face social exchange. When introduced to any social situation, virtual or physical, emoticons can be used to reinforce or subvert the verbal/textual message. They can change the message intent/content in as few as two keystrokes. [2] In the virtual realm, emoticons are often a subtitle for text and are often treated as a way to interpret the tone of the message. When bodily or verbal intonation infers one message and an emoticon is introduced that infers another or when both physical and textual cues are given, which is to be used as the interpretation? Do physical indications, or textual cues that are deliberately displayed, reveal the desired intonation?

intraInter socialite is an emoticon jacket with LCD screen (Fig. 1). The focus of the jacket is to create subtitles for interpersonal human interaction. The wearer uses force sensors to create computer textual subtitles for physical interaction. My investigation into wearable computing with this project is an inquiry into the loss of intonation and body language that occurs at the intersection of computers and textual communication as is evident in today's instantaneous communication and technology-centric culture.

This project explores emotional content and expression in multiple ways. The jacket:

- acts as a non-verbal, non-corporeal intermediary to a bodily and potentially verbal social interaction to create another plane of emotional meaning.
- potentially contradicts or detracts from that which is physically and verbally expressed.
- expresses, reinforces and clarifies that which is physically and verbally expressed.
- is a physical computing experience of a virtual communicative convention.
- expresses the development of an emotional and graphical mode of expression utilizing textual punctuation.
- explores whether a barrier or channel is created for emotional content through technology and physical computing.

The piece, *intraInter socialite*, asks several questions of the interaction between the user and the jacket and the social experience while wearing the jacket. Does the expression of content through electronic means become a prosthesis and/or hindrance for inter-human interaction? If it is a prosthetic, does an emotional language intermediary offer assistance for those with autism or empathic disorders? Is meaning lost and are its prosthesis capabilities diminished when precision is taken away? Emotional content is critical for daily communications and message interpretation. [3] How does the role/character of the interactor serve as a truth-teller and how does it help the user to reinforce false emotional reactions? [4] In this case, the natural method of conveying emotion through applied pressure, leads to an imprecise emotional connection and brings the emotion being conveyed into consciousness for both parties.

In this application, the effort put into replacing the nuances of personal communication with punctuation and textual cues in the virtual realm creates a subtitle for the conversation and interaction that occurs in the physical realm. It creates a range of implied emotion from the wearer. This also introduces an imprecise control over the emoticon displayed and the perception of the emoticon in the context of the interaction. The user has the ability to change the experience of the conversation when they attempt to control the level of emoticon displayed.

The techno-centric geek and socially inept express themselves more freely and create a powerful online or electronic identity through and behind the computer screen. The electronic veil is lifted through a forced vocabulary and a forced interaction in the human world. The wearer has only the jacket to hide behind, no computer screen and no alternate identity, pictures or avatar. With only a jacket in the middle of the interaction, the focus of the conversation may dramatically shift to the screen and what is being displayed. How does this create a “veil” even though the interactors are able to see each other in real-time physical space? Experimentally, adding the language of the virtual world to a physical interaction may allow the users to focus on the jacket instead of the interaction. [5]

Emoticons are an important non-standardized aspect of communication in virtual space that help convey emotion and additional meaning. They were created to help fill an emotional content void that was not being filled by short, text-based communication. Textual punctuation has become its own graphically and internationally interpreted language through emoticons. *intraInter socialite* attempts to study the effects of adding the emoticon to physical computing and interaction. It also calls to attention the use of textual elements to create graphical emotional elements to a virtual interaction. It allows the user to subtitle and create additional emotional content for the interaction, whether true or false.

A MYRIAD OF VIBRANT PHENOMENA: THE HIDDEN WORLDS OF AUDIOVISUAL ART-SCIENCE

MARCO MANCUSO

What is today recognized as "immersive art-science" is a form of creative expression meant to rise above the notion of art as abstract representation. This historical-critical statement of this lecture is to map those audiovisual artists acting with a "discovery approach", observing and recording, working without the use of video or digital techniques but obtaining the flux of sound and images only by natural and spontaneous scientific phenomena.

In his *De Rerum Natura* (*On the Nature of Things*), Lucretius denies any sort of creation, providence and original beatitude, stating that man broke free from his condition of ever present need through the use of techniques, which are transpositions of nature. The gods do exist, although they neither created universe nor they care about men's problems. Lucretius affirms that all our knowledge about nature shows us the universe as infinite, made by complex forms and composed by atoms. It follows natural laws, regardless of man's needs, and can be explained without resorting to deities. [1]

Nature as Art

Between 1899 and 1904 the German philosopher and biologist Ernst Haeckel published a book of lithographic and autotype prints entitled *Kunstformen der Natur* (*Art Forms of Nature*), one of his best known works and a symbol of his zoological research and philosophy, centered on the observation of marine micro-organisms and various natural species and animals. [2] The complete volume, consisting of over 100 lithographs, each accompanied by a short descriptive text, obtained a great success even among the non-specialist public and among some Art Nouveau artists, committed to find new models to be used in the nascent industrial design and in architecture.

In this regard, the volume lends itself to multiple assessments: as a zoological work depicting the evolution of organisms, as a work of art, as a book of aesthetics that focuses on observation and perception as a way of knowing. Aesthetics, as the science of beauty, intent on understanding the nature in relation to art.

The tables of the book, according to a geometric arrangement of the drawings, are based upon the microscopic siliceous skeletons of radiolarians and diatoms, the umbrellas of jellyfishes, the tentacles of sea anemones and spirals shells of molluscs. These illustrations depict therefore the law that regulates natural energy phenomena: the evolution, the fact that organisms are formed and transformed over time, according to genetic relationships of descent, from a common original type. [3]

Looking at these tables, we can see how nature is not only capable of creating spontaneous art forms, but also of establishing a direct connection with certain geometric aesthetics, starting from a fundamental unit/core and reaching a more complex entity, as consequent evolutionary practice of adaptation.

Numbers & Forms in Evolution

One of the most currently fascinating mathematical theories is the Theory of Fractals: according to the definition of its recently passed away discoverer, the polish mathematician Benoit Mandelbrot (1975), who started his researches from the fractal structure found out by french mathematician Gaston Julia in 1920, fractals are geometrical figures characterized by a repetition to infinity of a same pattern on a more and more reduced scale.

Mother Nature is filled with forms very similar to fractals, which don't follow in any way any of the rules of Euclidean geometry. A coastline, the branches or the roots of a tree, a cloud, the snowflakes, the zigzag lightning bolts and the leaf venation patterns: these are only a few examples of fractal forms spontaneously creating in nature. Among these ones there is the spiral, the fractal form par excellence.

So, how do we forget the hypnotic editing of energetic spontaneous fractal branches produced by a controlled electron beam, emitted from a cathode ray tube on a photographic paper, in the poetic audiovisual work *Energie!* by German artist Thorsten Fleisch? [4] And, what about the time shifts, animations and techniques for microscopic natural observation in John Campbell masterpiece *Li: The Patterns of Nature*, showing how the natural world itself, due to reproductive, conservative and evolutionary processes, can create complex architectures and structures based on physical, chemical, electromagnetic phenomena ? [5]

The procedural, generative, hieratic and evolutionary element can be considered the root of all these arguments, related to a modern "computational ecology": almost 40 years of studies, analysis and researches, have passed between Alan Turing's revolutionary theories about morphogenesis (the capability of every living being to develop complex bodies, starting from very simple elements, using self-assembling processes without an external guide) [6], which followed those by bio-mathematician Thompson D'Arcy in his work *On the growth and form* (1917), and more recent studies (1980-1985) on genetic algorithms (a particular kind of evolutionary algorithms utilizing mutation, selection and other recombination techniques in order to guarantee a certain number of possible evolutive solutions. [7]

Those researches were meant to point out the almost computational characteristics of Mother Nature on one hand, while on the other they confirmed the machines' capability of simulating/replicating complex natural phenomena.

Speaking deeply about pure mathematics and numbers, we could consider also the four dimensional Quaternions, discovered in 1843 by Irish mathematician William Roman Hamilton, who was searching for a way to extend complex number on a higher quantity of spatial dimensions. Quaternions find uses

today in both theoretical and applied mathematics, in particular for calculations involving three-dimensional rotations in computer vision: exactly what Thorsten Fleisch did in his work *Gestalt*. As stated by Thorsten Fleisch himself: "Given the fact that a film is the visualization of a mathematical element, it is theoretically possible to render it as high a resolution as technically feasible without losing any detail".

If we also take into consideration the definition of "Moirè effect" in the work *Spray* by Carsten Nicolai, the direct connection between the audiovisual outcome and the numeric and mathematical element is very clear. In physics, the Moirè pattern indicates an interference figure, frequently found in nature, composed by two superimposed grids at a specific angle, or even by two parallel grids with distanced chains in slightly different ways. The Moirè optical effect is regulated by accurate and complex sinusoidal equation where, at the variation of parameters and variables, correspond particular changes under the optical and visual point of view.

And again, one of the most important aspects of John Whitney's production was the artistic use of what he defined as "Computational Periodics": the achievement of a "series of harmonic events in the audiovisual presentation following a sort of digital harmony". [8] In 1966, the father of computer graphics developed the work *Permutations*, together with Dr Jack Citron at IBM laboratories as an artist-in-residence, where a specific simulation of a musical progression can be achieved through the multiple superimposition of graphic objects in order to create symmetries and counterpoints similar to the ones concerning rhythm and music.

According to Whitney himself: "In *Permutations* each point moves at a different speed and moves in an independent direction according to natural laws quite as valid as those of Pythagoras, while moving in their circular field. Their action produces a phenomenon more or less equivalent to the musical harmonies. When the points reach certain relationships (harmonic) with other parameters of the equation, they form elementary figures."

Visualizing Sounds

Again, in 1787, the jurist, musician and physicist Ernst Chladni published a book called *Entdeckungen über die Theorie des Klanges (Discoveries Concerning the Theory of Sound)*. [9] With this text, based on experiments on the field and observations, Chladni laid the foundations for that discipline within physics that came to be called "Acoustics", the science of sound. With the help of a violin bow which he drew perpendicularly across the edge of flat plates covered with sand, he observed how sound waves generate geometric patterns and shapes which today go by the term "Chladni figures".

In 1967, starting from Chladni studies, the Swiss doctor and naturalist Hans Jenny (1904-1972) published the book *Kymatik - Wellen und Schwingungen mit ihrer Struktur und Dynamik (Cymatics - The Structure and Dynamics of Waves and Vibration)*. In the book (and many video-recordings) Jenny carries out all his experiments that shows what happened when someone takes various materials like sand, spores, iron filings, water, and viscous substances, and places them on metal plates and membranes vibrating by specific sound waves. Jenny turned these materials into alive and fluctuating forms, following geometric patterns created by using simple vibrational waves (pure tones) present in the audible field.

With this publication, Hans Jenny laid the foundations of Cymatics, the science studying the wave phenomena: for more than 25 years, poet, producer and editor Jeff Volk has been making Cymatics popular

by producing all the books and videos that witness the experiences made by Swiss scientist Hans Jenny. [10]

The artists who paid homage to Cymatics studies was the American composer and musician Alvin Lucier, in the performance called *The Queen of the South*. Much of his work is influenced by science and explores the physical properties of sound itself: resonance of spaces, phase interference between closely-tuned pitches, and the transmission of sound through physical media.

All the Signs around Us

All these examples show clearly how Nature is characterized, at the root, by a matrix of numbers and mathematical expressions subtending a series of physical, optical, chemical-physical, electromagnetic phenomena influencing natural forms, species, colours, sounds and structures.

And when we talk about Nature, we intend also those electro-magnetic signals interferences hitting and surrounding the Earth that are the product of turbulences triggered by solar winds, coronal mass ejections and other energetic phenomena on Sun's surface combined with ionization in the upper atmosphere of the Earth itself. Semiconductor developed a whole part of their artistic career working on audio-visualization of these astronomic phenomena. Recording a series of sound materials, captured with a ELF-VLF radio recorder, a tool capable of converting ground level natural radio signals into sound frequencies, in works such as *Black Rain*, *Brilliant Noise* and *Magnetic Movie*, Semiconductor were able to give life to these magnetic fields.

If science is considered as a complex of knowledge obtained through a methodical procedure, capable of providing a precise description of the real aspect of things and the laws by which the phenomena happen, and if the rules governing such process are generally called "scientific method", then the experimental observation of a natural event, the formulation of a general hypothesis about such event and the possibility of checking the hypothesis through subsequent observations, become fundamental elements in modern scientific (and artistic) research.

What it is today recognized as "immersive art-science" is a form of creative expression meant to rise above the notion of art as abstract representation, in behalf of a multi-sensorial experience. The historical-critical statement of this lecture, and the *Hidden Worlds* screening connected to that, is to map those audiovisual artists acting with a "discovery approach", observing and recording, sharing experiences and ideas with scientists and science communities, working without the use of cinematographic or video or digital techniques but obtaining the flux of sound and images only by natural and spontaneous scientific phenomena (physical, optical, chemical, mathematical and electro-magnetical).

Immersivity awakens a synesthetic awareness, both in the mental and in the physical space. A myriad of vibrant phenomena, usually beyond the observer's reach, are instead made reachable through an accurate psycho-physical conditioning

The Hidden Worlds Project

The *Hidden Worlds* screening, curated by Marco Mancuso, produces works that induce into a critical reflection on the existing relation between audiovisual contemporary artistic research (as regards to cinema, video and digital experiences) and applied sciences. This project, dealing with different artistic examples which investigate new expressive forms for the representation of the sound-image relation, deliberately avoids focusing on the existing common aesthetics among them, as well as on a possible expressive language. It rather suggests an overview on specific systems for sensorial perception, and emotional mechanisms of "saturation", achieved through the use of hybrid techniques, that today like never before expand the tradition of analog experimental cinema and digital audiovisuals.

The video screening takes the spectators to wonderful "hidden worlds", illustrated by artists and scientists who, more and more often, collaborate and share experiences with one another on the research of new expressive potentialities within specific mathematical processes and physical, optical, chemical and electro-magnetic phenomena.

By watching the audiovisual representation of the existing energetic and electromagnetic phenomena on the Sun's surface and of current interferences generated from interaction of electromagnetic fields between the Sun and Earth, as possible instrument of aestheticization of the space phenomena by the Semiconductor duo (in works such as *Black Rain* and *Brilliant Noise*), the passage to the audiovisual representation of chemical-physical-optical reactions of Evelina Domnitch & Dmitri Gelfand, is extraordinary short indeed. In their first work present in this exhibition, (*Camera Lucida*) they study the chemical-physical phenomena of "sonoluminescence", while in their second one (*10000 Peacock Feathers in Foaming Acid*) they analyze the potentialities of optical phenomena generated by investigating the laser light within the nanometric structures of foams.

Moreover, if the work on "chemical grams" by the video maker Jurgen Reble (*Materia Obscura*) underlines the structures born out of a film's chemical corrosion, in the same way the first work by Thorsten Fliesch present in the exhibition (*Energie!*) shows the scorches on photographic paper produced by an high potential energy flow of an electron beam contained in a cathode ray tube.

The number is also an ever present concept, being the fundamental element of every mathematical formula which involves not only a single phenomenon present in nature, but also "superimposed" interferences, beats, accumulations, harmonies and other optical event, like Moirè's (optical illusion created by geometrical sequences of interference phenomena), as shown by the purely glitch and software works by Carsten Nicolai (*Spray*).

The number, in its highest abstraction of key element for a fourth dimension representation, is an important part of Thorsten Fleisch's video (*Gestalt*), a recognition of the quaternion worlds (four-dimensional fractals) visualized in a three dimensional space through an appropriate software. Yet maybe John Campbell's masterpiece (*LI: The Patterns of Nature*) is the work that mostly evidences the geometric structures spontaneously present in Nature, through a kind of magical and hypnotic audiovisual document.

MY LAWYER IS AN ARTIST: FREE CULTURE LICENSES AS ART MANIFESTOS

Aymeric Mansoux

Artists have the possibility today to publish their work under licenses that offer the same freedom as free software in terms of appropriation, study and modification. In this paper, I will argue that what is often introduced as a new form of artistic freedom and collaboration, is in fact a networked evolution of constrained art in which artists are turning legal documents into artists' manifestos.

Introduction

Most discussions around the influence of the free software philosophy on art tend to revolve around the role of the artist in a networked community and her or his relationship with so-called open source practices. Investigating why some artists have been quickly attracted to the philosophy behind the free software model and started to apply its principles to their creations is key in understanding what a free, or open source, work of art can or cannot do as a critical tool within culture. At the same time, avoiding a top down analysis of this phenomenon, and instead taking a closer look at its root properties, allows us to break apart the popular illusion of a global community of artists using or writing free software. This is the reason why a very important element to consider is the role that plays the license as a conscious artistic choice.

Choosing a license is the initial step that an artist interested in an alternative to standard copyright is confronted with and this is why before discussing the potentiality of a free work of art, we must first understand the process that leads to this choice. Indeed, such a decision is often reduced to a mandatory, practical, convenient, possibly fashionable step in order to attach a "free" or "open" label to a work of art. It is in fact a crucial stage. By doing so, the author allows her or his work to interface with a system inside which it can be freely exchanged, modified and distributed. The freedom of this work is not to be misunderstood with gratis and free of charge access to the creation, it means that once such a freedom is granted to a work of art, anyone is free to redistribute and modify it according to the rules provided by its license. There is no turning back once this choice is made public. The licensed work will then have a life of its own, an autonomy granted by a specific freedom of use, not defined by its author, but by the license she or he chose. Delegating such rights is not a light decision to make. Thus we must ask ourselves why an artist would agree to bind her or his work to such an important legal document. After all, works of art can already 'benefit' from existing copyright laws, so adding another legal layer on top of this might seem unnecessary bureaucracy, unless the added 'paper work' might in fact work as a form of statement, possibly a manifesto. In this case we must ask ourselves what kind of manifesto are we dealing with, what is its message? What type of works does it generate, what are their purpose and aesthetic?

The GNU Manifesto

In the history of the creation and distribution of manifestos the role of printing and publishing is often forgotten or given a secondary role. But, what would have become of the Futurist Manifesto without the support of the printing press and the newspaper industry in France and the rest of Europe? Not much, probably. So it is not without irony that one of the anecdotes often given to illustrate the motivations of Richard Stallman to write the GNU Manifesto, the founding text behind the free software movement, is tightly linked to the story of a defective printer. Indeed, very often, the origin of the document starts with a story about a problem Richard Stallman and some colleagues of his faced when Xerox did not give away the driver source code of the printer they had donated to MIT, preventing the hackers at the lab to modify and enhance it to fit their specific needs. In this case, this particular printer model had the tendency to jam and the lack of feedback from the machine when it was happening made it hard for the users to know what was going on. [1] Beyond the inability to print, and behind what seems to be a trivial anecdote, this event still remains one of the best examples to illustrate the side effects proprietary software can have in terms of user alienation. The programmers and engineers that were using the printer could have fixed or found a workaround for the jamming, and contributed the solution to the company and other users. But they were denied the access to the source code of the software. Such a deadlock is one of the reasons why the GNU manifesto was written. What is unique in this manifesto, is the idea that software reuse and access should be enforced, not only because it belongs to a long history of engineering practice, but also because software has to be free.

Looking at the text itself, we can see that the tone and the writing style used by Stallman make the GNU Manifesto closer to an art manifesto, than to yet another programmer's rant or technical guideline. As a matter of fact, we can read through the document and analyse it using the specific art manifesto traits that Mary Ann Caws has isolated based on the study of art manifestos produced during the twentieth century. [2] For instance Caws explains that "it is a document of an ideology, crafted to convince and convert." This is correct, the GNU manifesto starts with a personal story, turns it into a generalisation including other programmers and eventually involving the reader in the generalisation and explaining to her or him how to contribute right away. Caws also characterises the tone of manifestos as a "loud genre", and it is not making a stretch to see this feature in the all-capital recursive acronym GNU and the way it is introduced to the reader. It is the first headline of the manifesto and sets the self-referential tone for the rest of the text, as well as embodying a permanent finger pointing to what it will never be: "What's GNU? Gnu's Not Unix!" Furthermore, she reminds us that the manifesto "does not defend the status quo but states its own agenda in its collective concern", which is what Stallman does with the use of headlines to announce the GNU road-map and intentions clearly: "Why I Must Write GNU," "Why GNU Will Be Compatible with Unix," "How GNU Will Be Available," "Why Many Other Programmers Want to Help," "How You Can Contribute," "Why All Computer Users Will Benefit." the GNU Manifesto also instructs its audience on how to respond to the document with the presence of a final section "Some Easily Rebutted Objections to GNU's Goals" that lists and answers common issues that come to mind when reading it. Last but not least, manifestos are often written within a metaphorical framework that borrows its jargon from military lingo and for many the GNU Manifesto is being perceived and presented as a weapon, essential in the war against the main players of the proprietary software industry, such as Microsoft. In fact many hackers saw in the GPL an effective tool in "the perennial war against Microsoft." [3] Thus, when the copyleft principle, the mechanism derived from the GNU manifesto, is introduced in the 1997 edition of the Stanford Law Review, it is precisely described as a "weapon against copyright" [4] and not just a 'workaround' or 'hack'.

From the Manifesto to the License...

This particular concept of freedom, as it is expressed in the manifesto, is focused on the usage and the users of software. It will eventually lead to the maintenance by the Free Software Foundation (FSF) of a definition of free software and the four freedoms that can ensure its existence. On top of that, the GNU Manifesto is practically implemented with the GNU General Public License (GPL), that provides the legal framework to enable its vision of software freedom. It means every work that is defined by its author as free software, must be distributed with the GPL. The license itself works as a constant reference to the manifesto, by the way it is affecting the software and its source code distribution. Every software distributed with the GPL becomes the manifestation of GNU, and the license's preamble is nothing else but an alternative text paraphrasing the GNU Manifesto. This preamble is not a creative addition to the license, on the contrary the Frequently Asked Questions (FAQ) of the FSF even insists that it is an integral part of the license and cannot be omitted, thus making form and function coincide.

Even though the GPL was specifically targeting software, it does not take long for some people to see this as a principle that could be adapted or used literally in other forms of collaborative works. As early as 1997, copyleft is mentioned as a valid framework for collaborative artworks in which artists would pass "each work from one artist to another." [5] Of course, this is suddenly brought to our attention not because of the collaboration itself, but because of its sudden legal validity. Indeed the idea of passing works from one artist to another and encouraging derivative works is nothing new. For instance, back in the sixties, mail artists such as Ray Johnson even used the term "copy-left" in their work, [6] and it was possible on some occasions to spot the now very popular copyleft icon, an horizontally mirrored copyright logo, marking a mail art publication. In this context copy-left was seen as a symbol of "free-from-copyright relationships" with other artists in a way that was "not bound to ideologies." [7] In a strange twist, the use of this term is echoing years later, not without cynicism, in some reproductions of Johnson's works which are now stamped "Copyright the estate of Ray Johnson." [8]

So why a sudden interest in such practices? Precisely because of the growing development of intellectual property in the field of cultural production. At the time, under the 1976 copyright act, the only recognised artistic collaborative work was the joint work, in which it is required that all the authors agree that all their contributions are meant to be merged into one, flattened down, work. This made perfect sense in the context of the print based copyright doctrine but was clearly not working for digital environments where the romantic vision of the author is dissolved in the complex network of branches, copies and processes inherent to networked collaboration. This situation provided much headache to lawyers focused on the copyrighting of digitally born works. One of these works is for instance Bonnie Mitchell's 1996 "ChainArt" project, in which her students and fellow artists were invited to modify a digital image and pass it to someone else using a file server. In such a project the whole process and its different iterations are the work itself, not the final image at the end of the chain. The work exists as a collection of derived, reused and remixed individual elements that cannot be flattened down into one single 'joint work' and as a consequence, from a legal perspective, could neither be protected nor credited properly under the limited copyright regulations. [9] No surprise then that Heffan picked the Chain Art project as an example of artistic work that could greatly benefit from the GPL and the use of copyleft that can encourage "the creation of collaborative works by strangers." [10]

... and back to the Manifesto

Although this conclusion makes perfect sense legally, it clearly overlooks and diminishes the artistic desire to reflect upon the nature of information in the age of computer networks. Many artists adopted the GPL early on, not because of their wish to collaborate with strangers, but instead to augment their work with a statement derived from the free software ideology. For instance Mirko Vidovic used the free software definition to develop the GNU Art project, [11] in which suddenly, the GPL becomes a political tag, a set of meta data that could be applied to any work of art. By choosing the GPL as a means of creation and distribution, artists are aiming at implementing an apparatus similar to the digital aesthetics that Critical Art Ensemble (CAE) had described "as a process of copying [...] that offers dominant culture minimal material for recuperation by recycling the same images, actions, and sounds into radical discourse." [12] The weapon against copyright becomes a flagship for the recombining dreams of the digital resistance as envisioned by CAE. But by directly reusing the GPL, projects such as GNU Art failed none the less to really break through the position of Stallman that refuses to take part in judging if whether or not works of art should be free.

This is why a few lawyers, Mélanie Clément-Fontaine, David Geraud, as well as artists, Isabelle Vodjdani and Antoine Moreau, felt the need to make more explicit the artistic context and motivations of a liberated work of art by creating the Free Art License (FAL), equivalent to the popular free software GNU public License and articulated specifically for the creation of free art. [13] Suddenly, the license becomes an art manifesto. In the FAL the rules of copyleft are exposed, they stand on their own and enable the artistic creation, not for the sake of creating but as a means to produce singular and collective works. What is seen as freedom is just a very specific definition as envisioned in the GNU manifesto and that can only exist within the set of rules it represents. Moved to an artistic context, the rules to define freedom become a system to make art. In the same way that 'cent mille milliards de poèmes' was the 1961 OuLiPo manifestation of creative rules, the free art license is also a combinative manifesto, one that enables free art. It is not a simple adaptation of the GPL to the French copyright law, it is a networked art manifesto that operates within the legal fabric of culture.

Anyone who respects the rules of the FAL is allowed to play this game. Just like the ludic aspect in OuLiPo's work, and its probable root from Queneau's flirt with surrealism, artists who start to consciously use the GPL and the FAL solely for its 'exquisite' properties might start a superficial relationship with the creative process. Indeed, Raymond Queneau, co-founder of the OuLiPo reminded us already that we should not stop at the process' aesthetics itself because "simply constructing something well amounts to reducing art to play, the novel to a chess game, the poem to a puzzle. Neither saying something nor saying something well is enough, it is necessary that it be worth saying. But what is worth saying? The answer cannot be avoided: what is useful." [14] In other words and adapted to the FAL, the network aesthetics are not enough, their existence must be contextualised and positioned to escape its fate of a convenient technological and legal framework. This is why if the game aspect is obvious in the collective works that surround the FAL, we must see beyond the rules that are presented to us to perceive that such an artistic methodology aims to be an answer to the issue perceived by Chon in the analysis of the "ChainArt" project. Namely, to engage with the fluidity of information and try to turn the clichéd attitude of artists towards their unique and immutable contributions to art into a useful game. At the same time the emphasis is put on the collective nature of production and not community work.

The main issue with the intention of the FAL is that unlike the digital aesthetics modeled by CAE from Lautréamont's ideas, [15] the mechanism of a free art, against the capitalisation of culture and for the free circulation of ideas within the network can only work by making the machine responsible for this

very same capitalisation legitimate. While the mail art derivatives are happening outside of any obvious legal regulations, the copyleft art is literally hacking the system to reach a symbiosis and establish a kingdom within the kingdom. As a consequence these political works are very different from the artistic politics developed after the Russian revolution and World War I. Here, the artist is not an agent of the revolution but the vector of an 'arevolution'. A copyleft art is in the end not so much a critical weapon but instead a cornucopia that operates recursively and only within the frame of its license. Artists that are engaging with it, thus turning the license in a shared manifesto, cannot materialise an anti-culture, a counter culture, nor a subculture, they must create their own from scratch. Instead of seeking opposition and destruction of an enemy, they aim at founding and building.

Conclusion

If we look at 1897 Mallarmé's 'Un coup de dés jamais n'abolira le hasard', it is possible to only see it as an interesting visual design experiment in poetry. This approach misses the reason why this work exists in the first place. By turning art into the gathering and composing, even painting of both time and space within a text, it reached the apotheosis of parnassianism and symbolism upon which modernism broke through. [16] A similar issue of complex lineage and contextual information surrounds a document such as the FAL and leads to concurrent 'raisons d'être.' Indeed, the FAL is not just an 'exercice de style,' it is the embodiment of several elements that are announcing important changes in artistic practices: a call to turn legal rules into a constrained art system, a reflection on the nature of collaboration and authorship in the networked economy, a living archeology of the creative process by bringing traceability and transparency, and ultimately, the mark of an age of copyright and bureaucratic apotheosis that is pushing artists to develop their practice within the administrative structure of society and embed it in their creative process.

Unfortunately, and this is one of the reasons there is so much confusion and misunderstanding about the use of such licenses by artists and theoreticians, is that, with such a manifesto where form meets function, once the license is used, it triggers a process of rationalisation that leads to a fragmentation of the original ideology and intention into different, possibly contradictory, elements:

- A toolkit for artists to hack their practice and free themselves from consumerist workflows.
- A political statement against the transformation of the digital culture into what CAE calls the "reproduction and distribution network for the ideology of capital".
- A legal and technical framework to interface with the current system and support existing copyright law practices.
- A lifestyle, and sometimes fashion statement.

In practice it is possible for an artist to only see one of these facets and either ignore or not be aware of the others, making the license as manifesto multidimensional, open to different interpretations, not unlike the medium it was drafted in: the law.

INDIVIDUATION IN GENETIC ARTWORKS AND CAUCASIAN CARPETS

LAURA U. MARKS

This paper compares contemporary genetic artworks and 17th-century carpets from the Caucasus. Both are algorithmic works that respond to new information to reach results not prefigured in the algorithm's initial state. Caucasian carpets exemplify internal differentiation, individuation. In light of Grosz's argument that art's genetic impulse arises from sexual selection, they offer criteria for meaningful individuation in genetic art.

*Carpet, Caucasus, 17th C. Pergamonmuseum, Berlin; burned in 1945, parts survive. From Kurt Erdmann, *Oriental Carpets: An Essay on Their History*, trans. Charles Grant Ellis (New York: Universe Books, 1960).*

How can algorithms produce something that looks like life — acts like life — is, “for all practical purposes,” life? This talk pursues a comparison in the last chapter of my book *Enfoldment and Infinity: An Islamic Genealogy of New Media Art*, between two bodies of algorithmic art: contemporary generative artworks and 17th-century carpets from the Caucasus. This comparison may seem *recherché*, but I think it is pertinent because these carpets are perhaps the strongest examples of analog algorithmic artworks whose patterns arise not from top-down instructions but from internal differentiation, individuation. Both genetic artworks and Caucasian carpets respond to new information and come up with results that could not be prefigured in the algorithm's initial state. A problem I find with contemporary algorithmic artworks is that their developments lack strong, interesting motivations. Thinking about carpets, with help from some Deleuzian ideas, should give us a set of criteria for how meaningful individuation occurs in genetic art.

I assume this audience has some familiarity with genetic artworks, and not much familiarity with Caucasian carpets, so I'll begin by defining both. Generative artworks are algorithmic artworks whose algorithms respond to new information, such as inputs from the environment or from users. This allows them to come up with results that could not be prefigured in the algorithm's initial state. Caucasian car-

pets hail from the Caucasus, the ethnically and religiously mixed area that, historically, intersects northern Iran, Russia, Armenia, Azerbaijan, and Georgia. In the period I'm looking at, 17th and 18th centuries, when the Caucasus was politically controlled by Iran. Based on their shared genetic structure, this talk's task is to suggest some manners of individuation that Caucasian carpets offer for, and prefigure in, genetic art.

Genetic Artworks

Contemporary artworks made with genetic algorithms introduce software behaviors into environments produced by human interaction. Laurent Mignonneau and Christa Sommerer have been working with genetic algorithms since 1992, producing works that grow and change according to users' interactions with them. The works make their connection to biological evolution evident, in that they are plant-like or insect-like: the plant forms grow and branch, and the insect-like forms grow and reproduce, according to visitors' input. Sometimes this input is as simple as the amount of time a visitor spends in front of a screen (as in *Wissengewächs*, 2007, an interactive façade for the City of Science in Braunschweig, Germany).

Life Writer (2006) uses a manual typewriter input. The characters users type are translated into forms by assigning a standard ASCII value to each character; the resulting forms "eat" the input text, growing and reproducing. Users can't know what kind of forms their typing will reproduce; however, if they interact with the work for long enough they learn that the more they type, the more growth and individuation occur. This visually pleasing work answers the question, *What causes evolution?* by suggesting that evolution results from sustained engagement. Still, it leaves open the question, *What motivates evolution?* I am not making the argument here that interfaces should be more transparent, so that users can know intellectually what results their work produces. Maybe the slight mimetic relationship between users' gestures and the creatures' changes is enough to make the work satisfying. But in this, as in many other genetic artworks, the motivation seems slim. This is why I will look first to carpets, then to philosophy, for models of strongly motivated individuation.

Carpets as Algorithmic Artworks

Here's a detail of a Caucasian carpet. See how its motifs are figurative, but don't represent any figures we've seen before: they are a little like flowers, a little like animals, a little like crystals. Commentators on Caucasian carpets often refer to their forms as hybrid, "foetus-like," [1] anthropomorphic flowers and floral animals, and populations of "archaic, headless, two-headed beasts." [2] You can see these odd creatures for yourself.

Carpets, of course, are algorithmic media, in that a weaver follows a set of instructions in order to arrive at a predictable result. All carpets have some degree of automatization: the imposed structure of loom, thread count, knot style, and design. Nomad and village carpets allow for a lot of spontaneity on the part of the weaver. The carpets I'll show, however, were made for high-level courtly and religious clients. At the beginning of the 17th century, Shah 'Abbas of Iran supported economic development throughout his realm, and this stimulus may have established commercial rug weaving in the Caucasus. The size of the Caucasian carpets shows they were woven on large looms, suggesting commercial production. [3] They were woven from detailed cartoons that specified form, so weavers did not have much room for maneuver. However, the cartoons did not specify knots per form, giving weavers a bit of leeway.

This ratio between pre-given form and slight improvisation may account for the genetic development of the forms on Caucasian carpets. Pre-given, top-down forms individuate in unforeseen ways, producing genetic mutations that shock and delight.

Caucasian Carpets (and a Turkish one): A Model for Genetic Artworks

A couple of times in *The Movement-Image* Deleuze describes how the smallest elements of “flowing-matter” are perceiving, acting; alive. We do not need to see things, for things themselves already see: “The eye is in things,” he writes, referring to Bergson, who imagined that every point has a point of view that can be, as it were, photographed: “taken in the interior of things and for all the points of space.” [4] Deleuze describes the earliest life forms as tiny machines that perceive and react: “Biologists speak of ‘primeval soup, which made living beings possible, and where forms of matter known as dextrogyres and levogyres play an essential role’”: they produced micro-intervals, perceiving at one end, acting at the other. [5] Each point, then, to the degree that it resists top-down organization, is a living micro-interval that responds to its environment in unpredictable ways.

Even the most strictly ordered, hierarchical carpets produce singularities where idea meets matter. Here I show, not a Caucasian, but a Turkish carpet, that’s right here in Istanbul. This carpet follows a kind of cosmological organization, remarked by carpet scholars, whereby the central medallion suggests the beauty and divine order of heaven. See how the further we move from the center, the more unruly the forms get: they seem to possess an internal life force. I love this carpet because of the way the wacky flowers and cloud bands compete with the “transcendental” medallion. As though they’ve heard of heaven and they want none of it! This begins to raise the question, is there something in material that resists idealism, that has its own ideas of how to develop? And if so, what pushes it to develop?

Individuation

Let us define life as the capacity for individuation. While information, in-formation, is the creation of form from without, individuation comes from within. Gilbert Simondon writes that individuation occurs in a system that is metastable or out of step with itself. [6] I suggest we think of a sea or a lake as such a system. The individual form is not a final result so much as something like the peak of a wave: just a phase in process of individuation. [7] There are more potentials in pre-individual state than this individual. Becoming, then, is a mode of resolving an initial incompatibility that was rife with potentials: lots of other potential resolutions might have arisen. [8] In this awareness of the multiplicity of potentials, only one of which is actualized, we hear the resonance with theories of evolution, specifically Henri Bergson’s *Creative Evolution*. Individuation is the realization of a life force from within; the actualization of the virtual; a becoming.

Deleuze goes to great lengths in *The Fold* to uphold a free life force internal to matter that shapes it from within, each according to its capacities. He uses the concept of the univocity of being to argue that the Being of the universe is a field of unlimited potential that individuates freely, without any debt to Platonic and Aristotelian concepts of form. I want to emphasize that in fact this concept arises first in the thought of Abu ‘Ali al-Hussein Ibn Sina (980-1037), the Muslim philosopher from Bukhara whose innovative thought so immensely informed philosophy in both the Muslim world and the West. Deleuze indirectly acknowledges Ibn Sina’s concept of the univocity of being in some of his works, but the connection needs to be better acknowledged. [9]

Back to information vs. individuation. Algorithmic artworks obviously privilege information: they are formed by a pre-given set of instructions. Where does individuation occur in an algorithmic artwork? One locus of individuation is the machinic phylum of a given artwork, its particular nexus of material and immaterial production. Another is experimentation for the sake of seduction: the desire to give rise to beauty and pleasure may be the strongest provocation for individuation. Let me elaborate on these.

1. Machinic Phylum

I struggled a lot to find a source of individuation in algorithmic artworks, which would seem to be entirely pre-determined by their algorithms, until one day I saw it starting me in the face. Algorithmic artworks are not just numerically generated; they arise from nexes of idea and material that are completely particular. Given particular material, historical circumstances, drawing on existing programs that other people wrote in particular circumstances, the genetic artwork executes in a time and place that are, of course, different every time. So we can easily say that any algorithmic artwork arises from a *machinic* “assemblage” in Deleuze and Guattari’s sense of a singular nexus of ideas and materials. For example, each iteration of Sommerer and Mignoneau’s *Life Writing* assembles the analog typewriter interface, a text-to-form editor, the artists’ time, thought, practice, and conversation, funding from the University of Art and Design, Linz, Austria, and the actions and interest of users—in this documentation, at the Centro Cultural España in Mexico City.

Carpet making too is a machinic phylum specific to a culture, subject to its organizing principles. Caucasian carpets too arise from machinic assemblages. They required industrial-level design and production. Individuation occurred at the level of design, where it fascinates to try to reconstruct what was going on in the mind of a designer who drew an animal with eight legs and no head, for example. Individuation also occurs at the level of production, the decisions about knots per form that I think produced their genetically mutating forms. And individuation continues to occur in use.

Hence the fascination of Caucasian carpets, whose laws seems arbitrary, despite the industrial circumstances of their production. To me this suggests a lively competition between information and individuation.

Simondon offers a useful criterion for how technical production can create the unforeseen:

There is nothing essential about the made-to-measure aspect of the artisan's hand-craft. This derives from another, though essential, aspect of the abstract technical object: its being based on an analytical organization which always leaves the way clear for new possibilities, possibilities which are the exterior manifestation of an interior contingency. [10]

Similarly, in generative artwork, we may seek individuation at the level of programming and of material execution.

Seductive Novelty

We can certainly see a playful, experimental practice of pleasure in the way carpet patterns evolve. What about contemporary genetic artworks? The pursuit of beauty and pleasure seems such a retrograde motivation for contemporary art. It seems rather that genetic artworks, to the extent that the

artists aim to meet criteria for contemporary art, follow models of participatory and relational art. The artwork is supposed to change in response to some wish or need of the participant; this, in more radical versions, should be an ethical need. [11] I've interacted with any number of algorithmic artworks, genetic and otherwise, that practically begged me to invest them with meaning. But as with relational artwork, throwing the creative agency back onto the beholder or participant, demanding that we the visitors give the work its meaning, often results in random or lackluster outcomes. Such genetic works seem to follow the survival model of evolution: changes come about if enough participants select for them.

I think we need a stronger argument for what motivates individuation. What about this one: individuation arises from experimentation for the sake of beauty and pleasure! Moreover, the genetic impulse of art arises from sexual difference! This is the shocking thesis of Elizabeth Grosz in *Chaos, Territory, Art*. [12] In a brilliant feminist intervention, the Deleuzian philosopher adds sexual difference to individuation. Grosz picks up Bergson's point in *Creative Evolution* that we humans inherit all the creative solutions of other creatures from whom we differentiated at some point in evolution. [13] Bergson wrote:

The line of evolution that ends in man is not the only one. On other paths, divergent from it, other forms of consciousness have been developed," which are not as free from constraint as the human "but which, none the less, also express something that is immanent and essential to the evolutionary movement.

Clearly inspired by Bergson, Grosz rereads Darwin to argue that "survival" be construed in the broadest sense possible. Sexual selection highlights morphological differences that enhance the body's sexual appeal. Sexual display involves intensification—both of the one creating a spectacle of itself and the one perceiving. The wish to attract potential mates gives rise to all kinds of genetic inventiveness and experimentation, producing useless beauty. [14] Darwin writes that the mature male stickleback becomes "beautiful beyond description," colorful, translucent, and iridescent, during mating season. [15] To attract pollinators, flowers color their petals yellow and red and emit lovely scents. The bowerbird gathers colorful objects to decorate a stage for its courtship dance.

If we take the idea that evolution arises not from natural selection but from sexual selection, a universe of meaningful evolutionary beauty, seduction, and pleasure unfolds for us. The carpets I've shown are beautiful — and provocative, showing off their evolved embellishments much as the male stickleback shows off his colorful, iridescent skin. These observations about seductive evolution, in both carpets and nature, offer new criteria to artworks produced with generative software. In fact there are many digital and specifically genetic artworks that evolve in ways designed to keep our attention, to attract and delight us, much as the male bowerbird decorates his courtship stage. Critics often dismiss these works as decorative, not serious. But it is their ever-evolving beauty that makes them succeed. Beauty is an agent of evolution!

To conclude, I suggest that genetic and other artworks that rely on input from the user might try refining the random openness that so often motivates interaction. Further, they might try jettisoning the dreary, survivalist motives that incite "relational" interactions. Instead, retrograde though it may sound at first, cultivating beauty and experimenting with pleasure, may be the most generative of motives for individuation.

FUTURE NORTH

JANE D. MARSCHING

This paper discusses the intersection of climate forecasting, future prophecies, and science at the North Pole in one hundred years in the collaborative video work of artist Jane D. Marsching and architect Mitchell Joachim / Terreform 1, Future North.

Time takes on a different meaning in a landscape where the sun is up for half the year and it is dark for the other half, where there is no vegetation, no fixed land, no animal or biological rhythms. If the absence of visual cues can result in odd plays with our perception, including mirages, Ganzfelds, and other optical phenomena, it can also result in a destabilized notion of time. Further complicating this is the fact that the North Pole ice is disappearing, a quickening process outside of our historical images of the landscape. And finally, the North Pole climate is, as discussed earlier, the harbinger of climate change to come in more equatorial zones. Its sensitive and narrow climate parameters, more affected by tiny increments of change, show us in stark relief what we are barely able to distinguish in the landscapes around us. It shows us our future, in a way, and in so doing, is an early warning system.

At the North Pole the future is brought into the now. The endless streams of data, charts, graphs, and field images chart a landscape not dying, but transforming itself irrevocably away from the one that has enthralled us for so long. The sublime unchanging wilderness is becoming shabby around the edges and full of a nervous pathos. Whenever landscapes, cultures, technologies, etc., change quickly, our culture rushes to create new mythologies, new representations, to fill the gap. The rapid industrializations of the nineteenth century with the introduction of fast-moving trains, distance-bridging communications technologies, and labour-transforming factories, created cultures fascinated by simultaneity and fractured time and visual perception, among many responses. Futurism, Cubism and other movements were experiments on the forefront as the changes took place, tracking and testing new stories and new ways of seeing.

Today we are struggling to adapt to changes in our familiar images of the North Pole. The sad icons of dying polar bears and melting glaciers don't quite encompass the complexity of the disappearance of an entire terrain, an entire cultural phenomenon. Artists are grappling with this uncertain terrain, hoping to show us what is happening and what it means to the larger world. The same work is happening in the offices of scholars and workers many other disciplines: economists, climatologists, politicians, educators, and many others. What will the future bring at the North Pole? What is the significance of its disappearance? What will it become? What will we become in its absence? In this scenario, we can translate the age old adage "as above, so below" quite literally: "as far, so near."

The challenge is to take the abstractness of these graphs and charts, the overwhelming complexity of the data, and the sense of otherness in the landscape, and to translate it into terms we can grapple with in our prosaic lives. In climatology, studies of forecasting and predicting have to evaluate the risk factors and uncertainty of these models of future events whose actual outcomes have not been observed. Looking at the future of the climate of a specific biome requires complex forecasting not just of weather, but of economic, human, and technological parameters a century from now. This is so difficult that climate modellers have determined a "sweet spot" for climate predictability in a hundred-year parameter. Our culture demands this century marker, and policy texts have used it, including the IPCC reports, the Kyoto Protocol and others. The sweet spot, "maybe between 20 and 50 years out, is where the emissions scenarios don't matter too much and where the trends start to be discernable over the noise of year to year weather." [1] The point is to think about what we can know about one hundred years from now, particularly in a terrain so sensitive to climate triggers. Climate predictability can answer that question for 20 to 50 years hence, but falls into "total uncertainty" at a century out.

If science with its sensitive data and complex models cannot provide us with a satisfactory and entirely certain vision of a future North Pole, then who can? The social sciences, such as economics, use one set of data, futurologists, inherently interdisciplinary in nature, use many sets of data but profess that the future cannot be predicted. This absence of clear vision haunts us today. We have at our fingertips and

on our screens reams of data that attempt to outline this future, but the images are hazy, or too complex, or simply too uncertain. But as the future presses down upon us more and more, as ice melts quicker, as climate triggers become more apparent, as short-term predictions become reality sooner than expected, we long for future stories that can help to frame our predicament.

One such example is the very concrete phenomenon of sea-level rise and subsequent flooding. The Intergovernmental Panel on Climate Change's Fourth Assessment Report in 2007 gives six scenarios for sea-level rise over the next century. The lowest prediction is 7 inches and the highest is 23 inches. [2] A more drastic prediction has been made by Aslak Grinsted, a geophysicist at Copenhagen University, who estimates that the sea will rise by a metre over the next century. The finding was reported, among other places, UK Daily Mirror in an article entitled: "Sea will rise 'to levels of last Ice Age.'" [3] Jonathan Overpeck, director of the Institute for the Study of Planet Earth at the University of Arizona in Tucson, modelled a 6-meter sea-level rise submerging most of Florida. This data was discussed in the venerable National Geographic in a similarly spectacularly titled article: "Warming to Cause Catastrophic Rise in Sea Level?" [4] In Hollywood, Roland Emmerich's 2009 film 2012 shows the Statue of Liberty falling in the face of the enormous tsunami of sea-level rise. Today you can find numerous transparent blue overlays of sea-level rise in your home city as you search Google Earth. In one version you can look at what happens to your area if subjected to sea levels of 1 m to 14 m. The latter amount is the stuff of Emmerich's movie. It feeds off our fears and offers a satisfying narrative.

However, a 1-meter sea-level rise has been considered in many climate models. It doesn't depend on catastrophic events such as Greenland's ice sheet melting. On the other hand, a 3-meter sea-level rise is possible, though more likely it would take two or three centuries. This would flood most of Boston and other port cities. [5] It would be accompanied by major shifts in land use, significant migration, water scarcity, and myriad other climate-induced human affects. At the same time, the North Pole would be totally ice free for much of the year, an occurrence which we are on the verge of now. At that point, transportation routes would be established and geographic boundaries clear. The North Pole would be an accessible and open ocean, with a whole range of new stories of tourism, travel, marine life, etc.

This is the scenario among so many possible futures that we picked when I approached Mitchell Joachim, visionary architect and founder of Terreform1, with the question: if we had to live at the North Pole, what would our inhabited space look like? The end result is a 3-minute animation of port cities all over the world being flooded. As they flood, they are overlaid with ecotariums, a greenhouse-like structure that would maximize energy intake, include enough land and water to create habitable terrains, and be specific to each culture and landscape. These city-ecotariums then were detached from their larger landmasses and floated up towards an open north polar ocean, where they merge into one larger, nomadic, modular global city with shared resources.

The resulting animation is paired with another future prediction for the North Pole. A colour-field animation looks at the rise in temperature of 7 degrees Celsius over the next century. Degrees are coded with colours, just as cartographers use, with cooler temperatures being cooler colours, and warmer temperatures being warmer reds and oranges. As the temperature rises (under the control of randomizing software), the colours slowly warm. At the beginning of the piece, the colours of summer temperatures are in the pale yellow range, but after a hundred years of temperature rise, the summer colours are now warm orange verging on red. At the same time, an opera singer sings the headlines from Google News from 2007 when I searched for items associated with the term "North Pole". News headlines range from the first kiteboarder at the Pole, to oil company drilling, to climate science, to watercolour classes

in a small city in Alaska called North Pole. From the geopolitical to the mundane, from science to pastimes, the news headlines create a map of the North Pole as our culture imagines it today.

The pairing of these two videos – one a minimal evocation and one a lush narrative – with an operatic aria creates a complex space where data is offered in widely varying forms, which converge and diverge over time. The story of our future is given in versions that are based on our vision of the future now, on scientific data, and on future studies and interdisciplinary imaginings. Each one of these pictures is inherently full of risk and uncertainty, or, in the language of the IPCC, low confidence and high uncertainty. But they offer provocative and many-layered sensorial experiences that catalyze wonder, that offers a possible mythology, and that transforms the abstract and distant into a story.

Finally, different stories – the myth of the “first” explorer to reach the North Pole, the hole leading to a civilization at the centre of the Earth seen in flyovers and satellite images of the planet, webcams that offer both scientific data and an elegy to our image of the icy North Pole, a vision of a possible future nomadic urban cluster comprised of floating port cities from around the world – all circle the same centre. They are concerned with a terrain that is somehow at the heart of our culture’s imagination of a mythical and spiritual north. And yet this north is changing. The more it is charted, graphed, and pictured, the more our fears for our future in the face of catastrophic climate change cling to it like barnacles. Stories are needed to tell us about what is happening and what might happen. Science, with its cautious and specialized language and graphics, can give us information. But with only data, our imaginations are left to their own devices. The work of artists and writers is to weave the data with sensory experience, with perceptions in real time and space, with human emotions and memories, with cultural histories and predictions. In these stories, we linger over what is not known, over what might be, and over that which we hope for.

THE BANG THEORY: THE BREAKING AND (SORT OF) FIXING OF EVERYDAY OBJECTS

Luiza Martins

How might ill-designed or semi-broken objects be analyzed as to their potential to stimulate the development of new, personal and unique ways to interact with technology? Stemming from observations on faulty objects, this paper discusses the importance of an extended understanding of the aesthetics of use, misuse and individuality in the emerging theorizations of interaction design for an increasingly electronically mediated society.

Introduction

“As ever more of our everyday social and cultural experiences are mediated by electronic products, designers need to develop ways of exploring how this electronic mediation might enrich people’s everyday lives.” [1]

The complex nature of human relationships with electronic devices is an extensive and rich topic for research. Its relevance to the design practice is unquestionable and discussions surrounding the topic have exhibited all sorts of positions and perspectives from authors, designers and theorists. The full range of potentialities surrounding the use of electronic objects, however, is yet to be thoroughly explored; as technology infiltrates itself into diverse, broader areas of our lives, new structures and perspectives for the design of those objects become necessary. Ubiquitous technology does need not be equivalent to invisible technology: visibility and transparency may very well be valuable strategies in the emerging theorizations of product and interaction design.

Starting from the development of an experimental series of objects aimed at bringing the inner workings behind the surface of familiar electronic devices to the foreground, the paper discusses the relevance of a deeper understanding of the aesthetics of use, misuse and individuality of an object. The questioning of the role of both designer and user contextualizes these observations.

Improvisation and Negotiation

The project began with a few simple observations on how malfunctions in everyday electronic items changed not only one’s behavior towards these objects, but the rituals associated with their use. By shedding light on the invisible mechanisms that make up the core of an electronic device, malfunctions tend to bring out previously unnoticed potentialities in an object, opening up new dimensions as to the rituals and behaviors associated with it. Leah Buechley, in her article “Questioning Invisibility”, on invisibility in ubiquitous computing and its consequences, writes:

“First, the errors are engaging – they surprise us and force us to notice technology we might have otherwise ignored. Second, they introduce legibility to technology – they reveal interesting information about how it works.” [2]

The negotiation process with a malfunctioning object can provide useful insights into the relationships we develop with electronic devices. The flaw demands one’s time and attention in order to be fixed, changed or at least ignored. Learning to deal with those flaws leads to the development of singular rituals and behaviors associated solely with the object in question, effectively transforming it from a mass-produced good into a unique device by means of its use.

The first item to be observed during the development of the project was an old digital camera. The camera presented an odd fault which would make its display either exhibit all sorts of glitches or be completely black. With time and use, however, the owner of the device discovered that for the display to work properly it only needed a few rather vigorous slaps. After becoming acquainted with this specific malfunction in the object by using the device multiple times, one’s inclination was to automatically slap the camera as soon as it was turned on, incorporating a new ritual into the set of routine actions related to the use of that specific device.

Another item of interest in these first observations was a cheap blow dryer from a generic brand. Every blow dryer has a switch that automatically turns the device off when its internal circuits reach a certain temperature, in order to prevent overheating. This one, however, had a malfunction that automatically turned the device off every few minutes when in use. At first this behavior is quite puzzling, but eventually – also, after repeated use – one learns that in order to make the blow dryer work again it is necessary to puff air into the device until a small clicking sound is heard – the switch going off again. Eventually puffing air into the blow dryer every few minutes while using it becomes a ritual, a preventive behavior against that unique malfunction.

Exploring the complexity of these relationships was the first step in the development of the project; as a natural extension of these first observations and reflections, a call for contributions was posted in a handful of social media websites and art-related communities. The subject proved to be quite popular, as almost everyone in the targeted social circles had a similar account to share. The resulting contributions exhibited a wide variety of inventive solutions and behaviors associated to the problems of each device; one of the most striking affinities between the stories, however, was the attachment most people showed to these objects, despite their malfunctions. This attachment, although clearly dependent on many factors – socio-cultural background and income among them – was deeply related to the significance the person applied to the object, as well as its history. Many contributors commented that they felt that the malfunction made their object special and unique, something that only they knew how to use.

The Objects

Continuing the development of the project, the submitted contributions were used as a base to create a small series of experimental malfunctioning devices. First in the series was a faulty Game Boy, a portable video game console originally released by Nintendo in the early 90s. The object was based on the following contribution:

“I once had a video game console that would only work when flipped upside down.” [3]

The Game Boy was thus modified using a simple circuit bending solution: a tilt sensor was connected to the potentiometer responsible for controlling the screen’s contrast settings. This caused that specific part of the internal circuit to remain open when the device was placed right side up, so that the screen would appear blank while all other functions remained unaffected. When the game was positioned upside down, however, the tilt sensor caused the circuit to close, thus allowing the player to see the images on the screen (*fig. 1*).

The second object was a TV remote (*fig. 2*). The device was adapted to fit the following contribution:

“My remote never worked unless I squeezed and twisted it really hard.” [4]

The device was modified by placing small pieces of adhesive tape over its internal button contacts, making it necessary to twist the remote and press each button very hard in order for it to work. The previously mentioned hair dryer rounded up the series as the third object (*fig. 2*). All of the objects were painted white in order to strip them of their brand names and individual attributes, instead presenting them as generic depictions of familiar devices.

With the objects ready, the next step was to observe people's reactions to their malfunctions. A few, informal tests were conducted in order to understand and recognize different perspectives and attitudes towards the devices. Since the project's aim was not that of a scientific study, the tests weren't conducted with a scientific method in mind. There were no initial conjectures to be proven: instead, the goal was to solely observe the effects and affects of an artistic experiment.

Right from the first test it became clear that most people tended to have a pattern of behavior towards malfunctioning electronic objects: twisting, plugging and unplugging, banging and shaking seemed to be part of an acquired gestural vocabulary towards glitchy items. After the first few unsuccessful interactions, however, most people tended to start a more careful exploration of the device. This second phase usually led to interesting results, with each person developing their own, individual and performative responses towards different malfunctions. Some people tried to adapt themselves to the situation by developing new ways of using the device; others tried to correct the faults with other, external solutions, like using other objects as aids and tools. It is interesting to note that, regardless of the problems, very few people stopped using the devices altogether; most tended to be amused and challenged by the objects and thus tried their best to work out a way to use them in spite of their defects.

The Aesthetics of Misuse

"Concept art is theorized as a perceptual process in which the image (concept) is experienced as an immediate presence – an art that presents to the viewer/listener an experience to be completed through the very act of perception." [5]

Building upon LaBelle's views on concept art, the design of electronic objects can be theorized analogously; the perception of the experience of use needs to be considered an integral and essential part of the identity of an object. Under these terms, the object would be an incomplete entity in and by itself: only through use the rituals and behaviors associated with it would complete the picture. LaBelle goes on to quote Nam June Paik as stating:

"In a nomadic, post-industrial time we are more experience-oriented than possession-oriented." [6]

Experience thus becomes a material in itself, as much as all tangible components that make up the physical representation of the electronic object. This set of intangible attributes, albeit abstract, is decisive in the definition of a device's identity.

During the development of the project one of the most significant questions raised by all the experiments and contributions concerned the reasons that made most people keep using malfunctioning objects, aside from the conspicuous financial issues. Electronic items with proven malfunctions can be returned to their manufacturers or sellers with relative ease; there is, admittedly, a very strong influence of psychological and socio-cultural matters that can explain the reasons for the decision to keep such an object. As a result, a multitude of answers are plausible, ranging from the object's history to its functionality; nevertheless, what strikes as a particularly interesting in the research is the usual connection of this decision to live with the necessary rituals and behaviors as part of the development of a relationship with that object, almost to the point of emotional attachment to the very flaw that was problematic in the first place. What was initially considered a malfunction becomes, then, a defining trait in an object, asserting its individual identity in a sea of mass-produced goods. An aesthetics of misuse thus emerges, as an essential transformation of the individual's interaction with the object.

Reflection on imperfect objects is not a new subject in design research. Let it be noted, however, that electronic objects represent an entirely different category of objects; the rich field of possible iterations and interactions, as well as the behaviors associated with them, cause the experiences associated with this kind of object to be of a completely different nature.

Conclusion

“The most difficult challenges for designers of electronic objects now lie [...] in the realms of metaphysics, poetry, and aesthetics, [...] the post-optimal object could provide new experiences of everyday life, new poetic dimensions.” [7]

By stimulating and nurturing individualized responses and uses, explorations on the misuse electronic object can open up a new range of possibilities beyond the realms of efficiency and results. Design takes a new role, not as an instrument to the imposition of values, meanings and hierarchies; instead, by making the individualized input an essential part of the construction of the identity of an object, the figure of the user can be elevated to a new level: that of an actor. Whereas the user merely abides to an aesthetics of use already defined by the designer as the embodiment of an ideological system and is, ultimately, subdued to the machine, the actor embodies a new perspective on interaction design, where machine and human share the same hierarchical space. Dunne writes:

“According to Virilio (1995): ‘Interactive user-friendliness’... is just a metaphor for the subtle enslavement of the human being to ‘intelligent’ machines; a programmed symbiosis of man and computer in which assistance and the much trumpeted ‘dialogue between man and the machine’ scarcely conceal the premises: ... the total, unavowed disqualification of the human in favor of the definitive instrumental conditioning of the individual.’

This enslavement is not, strictly speaking, to machines, nor to the people who build and own them, but to the conceptual models, values and systems of thought the machines embody.” [8]

The actor has an active role in the questioning of this enslavement to pre-fabricated behaviors. By subverting the notion of a generic travesty of the user, the actor has the power to open up a new range of poetic and metaphysical possibilities as to human relationships with electronic objects. Growth towards a new notion of technology is, however, of prime importance, as its visibility plays a central part in the shifting of roles from user to actor. By completely obliterating visibility into the technological workings behind the surface of an electronic device a rich source of new experiences and perspectives towards the object is lost. Buechley writes:

“Invisibility is a narrow design goal. It’s not necessarily a bad one, but it doesn’t capture the full range of technological or creative possibilities.” [9]

“Why should ubicomp – or any other computing discipline, for that matter – consign itself to the ignored, invisible realm?” [10]

Marcel Duchamp considered his readymades as a response to purely retinal art, creating additional dimensions to the artistic object not yet explored at that time; taking cue from this idea, malfunctions

have the potential to respond to the perception of product design as a discipline merely focused on results, usability and user–friendliness, particularly in an era where electronic devices tend to mediate more and more areas of our lives that are less dependent on these factors.

“The electronic object does not have to fulfill our expectations; it can surprise and provoke.” [11]

That doesn’t mean, surely, that dysfunctional design should be the main goal for the development of meaningful experiences in and for itself; it is, however, a path to be explored and observed as useful and playful critique. Questioning the role of the designer as merely responsible for

“creating semiotic skins for incomprehensible technologies” [12]

is essential to the development of design practice itself.

“a ‘space’ of chains and layers of meaning between the object and the viewer, continuously expanding with no fixed origin or closure.” [13]

Understanding interaction design through Roland Barthes’ definition of text might be a useful beginning.

THE SOUND OF SMALL BRAIN CIRCUITS: PLASTICITY AND SYNCHRONISATION IN THE NEUROGRANULAR SAMPLER

JOHN MATTHIAS

This paper explores some control strategies using synaptic plasticity in the simulation of an artificial network of spiking neurons in the Neurogranular sampler - a musical instrument which triggers grains of sampled sound when the neurons 'fire.'

A raster plot showing the spiking behaviour of simulation of a network of 64 neurons modelled using the Izhikevich Model (2004) copyright Kevin McCracken.

Introduction

The Neurogranular Sampler is a software musical instrument which triggers grains of live sampled audio when any one of a network of artificial spiking neurons 'fires' [10,11]. The level of synchronisation in distributed systems is often controlled by the strength of interaction between the individual elements. If the elements are neurons in small brain circuits, the characteristic event is the 'firing time' of a particular neuron. In this paper we propose how we might 'neuroengineer' the collective firing behaviour of small networks of artificial neurons and therefore also engineer the sound of the Neurogranular sampler by exploiting a counter-intuitive property of Neuronal Plasticity.

Plasticity

The term 'plasticity' in the neurosciences refers to the ability of neurons or nerve cells to adapt their connectivity according to the electrical activity of the other cells in the network. The ability for cells to

make new physical synaptic connections via axonal growth and synaptic growth and decay (synaptogenesis) is known as structural plasticity. [1] In this scenario, the axons (long tubular structures) from neurons grow towards other active cells through an induced chemical gradient, a process which has a timescale of hours to days. A different category of plasticity is known as 'Spike Timing Dependent Plasticity' (STDP) and refers to the millisecond strengthening and weakening of connections between neurons as a result of the transmission and reception of *causal* spike signals between neurons. [2]

This 'causal' effect was initially proposed by Donald Hebb and is known generally in the literature as 'Hebbian Learning.' [3] Essentially, the idea is that connections between neurons become post-synaptically strengthened (i.e. in the direction of the motion of the spike signal) if the pre-synaptic neuron fires before the post-synaptic neuron. In the Spike Timing Dependent Plasticity scenario, this has been refined such that the change in the strength of connections is dependent upon the relative timings of pre-synaptic inputs and post-synaptic spikes. [4]

This continuous strengthening and weakening of neuronal connections resulting from the timing of neuronal stimulation and the relative timing of the resultant spiking behaviour coupled with the effects of the differing transit times of spike signals according to axonal topologies, has led to the idea of 'Polychronisation' (not at the same time, but in clusters). This term put forward by Izhikevich and others describes the formation of groups of neurons which fire according to particular sensual and cortical inputs. [5] A neuron can be a member of any number of such groups, meaning that it is not simply the number of neurons which is involved in neuronal processing, but the combinatorial number of possible polychronous groups, which in the human brain is a number larger than the total number of elementary particles in the Universe.

The idea that patterns and sequences of neuronal firing might be associated with particular sensory inputs has been around for a long time (see for example [6]), but it has only been relatively recently that this has begun to be understood at the level of the micro-dynamics of networks of cells. At this dynamical level, the interplay between model parameters associated with neuronal topologies, spike transit times (often called 'delays' in the literature), sensory input, synaptic plasticity and global 'noisy' inputs crucially affect the robustness and formation of polychronous groups and the associated spike timings.

These models of small brain circuits provide us with a very rich dynamical palette with which to experiment on the controlling of sound, by using the 'spike' signal of an individual neuron to trigger sonic events. Typically, in neuro-technological or neuro-engineering contexts, the spiking output of a network of artificial spiking neurons goes through an 'encoding process' and is sent to a 'motor' control, such as those which might control the movements of a robot, for example. [7] One example of this encoding process, is called 'rate coding' in which the frequency of the spikes generated in the output of the network is interpreted and used as a control parameter, the resulting behaviour from which is fed back to the network. [8] In our work, directed towards sonic control, the spiking output *is* the motor output, and in a sense the artificial neurons in our system have triple sensory, cortical and motor character. [9]

The Neurogranular Sampler

In the Neurogranular Sampler, [10] the spike signal from any artificial neuron from a number of cells specified by the user triggers a single 'grain' of sound, either from a 'live' microphone, or a pre-recorded sound file. Typically, these grains can be between 20 milliseconds and one second in duration. We can choose different kinds of neurons, which exhibit different kinds of spiking behaviour (Regular Spiking or

Bursting, for example) and choose either a homogenous group of neurons or a heterogeneous group (a selection of different types). If the group of neurons is chosen to be homogeneous and of 'Regular Spiking' variety, we find that the network of spiking neurons rapidly enters a dynamical state in which the neurons fire together –almost in synchrony (see Fig 1). In the diagram Fig 1, the firing activity in a simulated network of 64 neurons (labelled on the 'Neuron Index' axis) is shown over a period of 2000 milliseconds, or two seconds. A dot on the diagram, or 'Raster Plot' as it is known in the neuroscience literature, indicates a firing 'event' from that particular neuron. Vertical lines on this diagram indicate synchronous firing behaviour meaning that the instrument will exhibit pulse-like behaviour, the frequency of which can be controlled by a 'stretching' or compression of the audio signal. We can move away from this synchronous dynamical state in several ways; one way is to introduce heterogeneity into the system, i.e by introducing different kinds of artificial neurons. This acts as a kind of structural disorder, making the synchronous state impossible. Perhaps surprisingly, another way of moving away from the synchronous state is to exploit a recently discovered property of synaptic plasticity in small brain circuits by Lubenov and Siappas. [11]

Controlling Synchrony

Lubenov and Siappas showed that if the neurons in a network of artificial regular spiking Izhikevich neurons are all initially in a synchronous regular spiking state, the introduction of Hebbian Spike Timing Dependent Plasticity into the model network rapidly takes the network into a very uncorrelated state, in which the spiking patterns are almost indistinguishable from a random pattern (lubenov ref). As the neurons' firing times are already initially synchronised, the adaptation of relative spike times due to the changing of the connection strengths introduced by the plasticity algorithm can only have the effect of taking the spikes out of synchrony! The network subsequently gradually re-aligns itself temporally and self-organises to a state at the 'border between randomness and synchrony.' [11]

We can exploit this in our Neurogranular sampler instrument –in this way synaptic plasticity is being used as a control mechanism to 'de-synchronize' the network of neurons. It is possible to use an Anti-Hebbian algorithm [11] in order to re-establish the initial regular spiking synchronized state and we can follow the correlation in the network spiking behaviour using an 'order parameter' which is a function and a phrase borrowed from condensed matter physics.

BENDING LIGHT: STRANGE TALES FROM THE PROJECTIVE PLANE

Alex May

This paper presents an overview of the ongoing research and art practice from the Quadratura Video Projection Research Laboratory, which is concerned with exploring the medium of light; mainly through the utilisation of video projection and mapping techniques and disparate technologies coupled with more traditional optics such as mirrors, lasers, and illusions.

Shadows of Light #2, 2011, Quadratura, video projection, Copyright Quadratura Ltd.

This paper presents an overview of the ongoing research and art practice from the Quadratura Video Projection Research Laboratory, which is concerned with exploring the medium of light; mainly through the utilisation of video projection and mapping techniques and disparate technologies coupled with more traditional optics such as mirrors, lasers, and illusions. Quadratura also develop interactive works that explore the role of the observer in art; subverting the traditional one-way communication and creating emotive interactions that can either encourage and/or discourage participation within the viewing 'agreement'.

Each project from Quadratura has necessitated some degree of in-house software development as ideas and concepts within the work have evolved. The main focus, PatchBox, is a highly complex and specialised application; an amalgamation of six years exploration into video mapping techniques. It is capable of a wide range of functionality, from performing simple affine transformations of video onto arbi-

rary flat surfaces, to dynamically mapping any combination of real and virtual geometry onto any physical structure from multiple video projectors, from multiple physical viewpoints to facilitate real-time, high resolution, digital trompe l'oeil effects.

PatchBox is designed in such a way as to be flexible enough to be used as a VJ performance tool, a rapid urban video projection bombing system, or for long running multi-screen interactive installations. However, it was never designed to be a commercial product, or indeed used by anyone outside of Quadratura. This decision has facilitated a rapid development schedule as it is not ever had to be used by a third party; rather it only has to keep pace with our artistic requirements.

Video Mapping

PatchBox was first utilised in 2007 for a large scale audio/visual installation in the historic Holland Park located in London; a major commission by Kensington and Chelsea Council. Alex May (real-time video artist and programmer) and Martin A. Smith (sound artist and composer) – who would later become the directors of Quadratura – developed a series of original video projection and lighting installations that formed a darkly cinematic narrative through the ancient wooded section of the park taking visitors on a sublime journey through life, death, and remembrance. PatchBox was used to map a multitude of different blinking eyes (looping video clips) across the canopy of a 30 foot tall oak tree from a single laptop powering one video projector. The real-time functionality allowed dynamic placement and adjustment of each video element.

More recently, Quadratura created a large scale, site-specific architectural video projection mapping for the 2011 Kinetica Art Fair in London. The installation, entitled “BioReactor”, was conceived and developed in collaboration with bio-artist Anna Dumitriu who described it as:

“A dirty wetware body, thick with bacteria and mutated by electromagnetic fields, which learns to feed off the digital technology that surrounds it, leeching energy from every data source and transforming - not only itself but also the world around it.” [1]

PatchBox was utilised to accurately map video onto the complicated architecture of P3 in London where the event was taking place. Due to the dynamic nature of the mapping system, it took just 10 minutes from turning the computer on to a final, pixel accurate alignment.

Interactive Installations

Since 2008 Quadratura have been developing interactive video installations exploring the relationship between art and the observer.

In 2009 Quadratura exhibited a series of interactive video installations in London entitled “Shadows and Falling Light.” Each installation was carefully designed to present a different form of interaction to the visitor without needing to be explained in any way. This was achieved by devising one or two simple abstract ‘rules’ per installation that would be quickly understood.

“Shadows of Light” rewarded visitors that stood still, rather than moved about. As the visitor stands still, their silhouette is slowly drawn onto the wall in a randomly picked solid colour. If they stand still

even longer they find that the silhouette will begin to act as though it is spray painted, causing drips of 'paint' to start streaming down the wall.

Conversely, "Mesh" is a constantly moving mesh of electric blue lines. Touch any of the lines and it will break them like a beam of light. The mesh will attempt to reform around any physical obstruction (the visitor). Visitors tended to slowly stop moving so they wouldn't break any more beams.

Before 2011, Quadratura had developed their own technical solutions for tracking visitors as they interacted with the work based on infrared illumination and various background subtraction algorithms. In November 2010 Microsoft released the Kinect: a peripheral designed for the Xbox 360 that featured a video camera and depth camera. By utilising the depth camera it became almost trivial to segment and track visitors. While 'Kinect Hacking' has become a world-wide phenomenon, and there have been a great many examples of artists creating and developing concepts on the hardware, Quadratura believes that it was the first to publicly exhibit a Kinect based artwork in a gallery: "Shadows of Light #2" (2011) at Kinetica, London, February 2011.

"My Robot Companion" (2011) was a series of robot heads designed to promote discussion of the ethical issues of how we might relate to robots in society, created as part of Alex May & Anna Dumitriu's collaboration as artists in residence at Hertfordshire University working with the Adaptive Systems Research Group (ASRG). Exhibited at the Science Gallery in Dublin (June-September 2011) as part of their HUMAN+ show, the installation centred around 'Charley', a humanoid research robot created by Dr. Michael Walters from the ASRG, with a stripped down Kinect embedded on its chest, and featuring a video projected head. As visitors approached the robot, it would turn its head towards them, and its face would slowly morph into theirs. If more than one visitor stood in front of Charley, its face would become an amalgamation of all of their faces. It was designed to explore how people felt about a robot that looked (progressively) like them and/or their family, and at which point the "Uncanny Valley" effect might kick in. [2] "My Robot Companion" was awarded joint first prize for public understanding of artificial intelligence by the Society for Artificial Intelligence and Simulation of Behaviour.

Conclusion

Video projection is a powerful medium; it is able to non-destructively alter the appearance of surfaces on a large enough physical scale to present the observer with an environment that can be almost entirely digitally manipulated in real-time in response to their motion, pose, and proximity. Some instances of Quadratura's interactive artwork require observation to exist in any meaningful way; although the communication between the observer and the work is allowed to evolve within the artistic constraints designed into the system, whether it is physical, verbal or otherwise. Our challenge, therefore, is one of creating meaningful communication within the boundary of the technology.

RECOGNITION AND RESPONSE TO HUMAN MOVEMENT CONTAINED IN MOTION CAPTURE DATA USING THE SELF ORGANISING MAP

John McCormick

Neural Networks have been used successfully for recognition of human gestures in many applications including analysis of motion capture data. This paper investigates the potential for using the same methods for both recognition and synthesising responses in relation to movement contained in motion capture sequences.

Representation of the trained Self Organising Map with neurons containing clusters of similar patterns derived from the motion capture data.

This research arose from questions regarding the nature of collaboration and the use of immersive digital sound and visual environments as a component of live dance performance incorporating real-time motion capture data. Human collaborators are able to make use of their experiences and memories to respond to developmental concepts and synthesise possibilities in relation to a new artwork. If the software environments or agents were to be considered part of the collaborative process, what traits would be beneficial to them? Some form of memory would be useful, so the agent would have references to apply to incoming stimulus, or some substance with which to synthesise possibilities.

In contemplating the software agent as collaborator, even in a very limited sense, this research considered models of software that attempted to mimic human brain functions. Artificial Neural Networks (ANN) attempt to model the behaviour and capabilities of neural networks in the brain, and have been popular in the area of machine learning, including the field of gesture recognition. While there have been many successes in the area of gesture recognition using artificial neural networks, [1] [2] in human communication that recognition may often be a precursor to a response and a solution was sought that offered possibilities of both recognition and response especially in relation to human movement contained within motion capture data. There are many types of ANN however this research currently employs a particular type of ANN, the Self-Organising Map (SOM) or Kohonen Feature Map, after Teuvo Kohonen who first described them. [3] [4]

The Self Organising Map is an unsupervised form of neural network in that there is no ideal output suggested to the network, only the input data is provided. Furthermore the input data is not necessarily labelled in any manner so it is up to the SOM to find any patterns within the data and to group these into classes.

Sequences of movement were captured using both Motion Analysis and Optitrack optical motion capture systems to determine if the method was system independent. Both systems used multiple cameras to record the positions of reflective markers attached to the body of the dancer. The data was produced to represent both limb position as defined by marker positions and a hierarchy of joint rotations. This allowed testing of the SOM with the most popular representations of motion data, i.e. position data or joint rotation data. The SOM chosen was represented as a 10 X 10 array of neurons giving 100 neurons competing to classify the samples of motion data. The motion sequences were around 3000 frames long and each frame was treated as a sample by the network. Within each frame there were either 34 marker positions (the number of markers on the dancer's body) or 19 joint rotations, and each of these represented by a vector (x,y,z) , so a total of 102 position values or 57 joint rotation values. Each frame containing all of these values was presented to every neuron and the one deemed to have the closest match (Best Matching Unit, BMU) is the winner and the map is adjusted accordingly. A weighting for the winning neuron and a decreasing number of neighbouring neurons are adjusted and over many iterations a weighting map is formed that increasingly matches the topography of the input data. The final map can be visualised in a number of ways, but perhaps the most pertinent to this paper is in the form describing the number of clusters or hits each neuron achieved.

Figure 1 shows the number of frames each neuron gathered as a class or cluster with similar data patterns. The patterns here, being frames of mocap data, could be considered dynamic postures extracted from the movement sequence. To test the trained network, mocap data representing a limited number of movements of known composition and length was introduced and the resultant neuron map compared to the map of the trained network. For example the main sequence contained a few hundred frames of the dancer in T-Pose (standing with feet together and arms out to form a T shape) at the start of the sequence. A short sequence of mocap data containing only T-Pose data when presented to the trained network resulted in all the frames stimulating the same neuron that contained the T-Pose samples from the original sequence. This pattern was seen when presenting other short, known movement postures to the trained network. The classification or recognition of the movement data was seen in both position and rotation datasets, though the resultant maps were different in the distribution and number of hits each neuron accumulated.

The SOM proved to be a robust method for classifying motion captured movement. It was able to create a map of movement frames which could be used to classify or recognise further incoming motion data.

More importantly for this research, it was able to create a map that could be treated as a type of memory of the dance as represented by the motion data. Traversing the map in different ways could lead to responses that are inherently related to the memory of the performed movement, but with the potential to create variations on the movement as responses to incoming motions. This is possibly analogous to the process displayed by human performers when improvising or developing movement and it is this re-synthesis or traversing of memory in order to produce movement responses that is the current stage of this research.

The results have pointed to a number of further possibilities relating to live performance. Multiple maps representing different components of the performance; movement, sound, images, could be trained and then traversed simultaneously during the performance. The use of multiple maps may be analogous to the processing of specialised information by different parts of the brain and could be used with some higher function logic to co-ordinate the synthesis of the multiple elements.

HOW LOCATIVE MEDIA ART SET THE AGENDA FOR MOBILE LOCATION AWARE APPS (AND WHY THIS STILL MATTERS).

Conor McGarrigle

This paper argues that locative media art has had a significant role to play in the shaping of emergent location-aware technologies with this influence very evident in the latest generation of locative smart-phone apps.

It is argued that this influence goes beyond superficial similarities in approach but rather represents a shift in thinking about location which has far reaching implications for the future of location-aware applications.

NAMALand, 2010

Introduction

This paper explores the connection between Locative Media (LM) a set of art practices centred on location aware technologies and current Location Based Services (LBS) and applications. To achieve this LM

will be traced to the origins of the term and to the originary ambitions driving this unique mode of engagement with emergent location-aware technologies. This involves returning to the first principles of the Karosta Locative Media workshop, its associated texts and to Ben Russell's "Headmap Manifesto" [1] to locate the intentions and ambitions embedded in the term itself.

From its inception it can be said that LM has set itself the task of defining modes of operation for emergent locative technologies. These emphasise the technology's ability to augment space through revealing layers of meanings and associations which act to foreground the rich lived experience of place. With the growing ubiquity of locative technologies I propose that LM exerted a significant influence on these unfolding technologies shaping the application of the technologies resulting in a more user centred experience which opens the technology to a wider constituency beyond the realm of specialists. This influence goes beyond the specifics of similarities in approach between particular applications and artworks, representing a shift in thinking about location which has implications for the future of locative applications.

The Ambitions of Locative Media

The term "Locative Media" originated at the Locative Media Workshop which took place in Karosta, Latvia in July 2003. The term was originally employed to distinguish the questioning artistic uses of locative technologies from their instrumentalised commercial and military uses. The proposition was that locative technologies, which had at this point only recently become widely available for civilian use, represented a fundamental shift (or the means to bring about such a shift) in our perception of geographic location. That the artistic uses of these technologies not only represented a new artistic form but had an important role to play in the opening up of the possibilities of these media to everyone. It was the embodiment of Ben Russell's prescient predictions in the Headmap Manifesto,

what was once the sole preserve of builders, architects and engineers falls into the hands of everyone: the ability to shape and organise the real world and the real space. [2]

Russell correctly identifies the potential of the convergence of high bandwidth mobile internet and location awareness in mobile devices to overlay real space with a geographically referenced layer of annotation and context sensitive information. His interest mirrors that of the Ubicomp community of researchers but his concerns focus on the privileging of user-centric practices and the aspiration that these technologies become tools for creation rather than solely consumption. This concern echoes those expressed by the creators of urban annotation project "Urban Tapestries" that practices emerging around locative technologies (in 2003) were "unnecessarily impoverished" [3] a concern which Urban Tapestries sought to address.

LM can trace its origins to the year 2000 when "selective availability", an intentional degradation of the Global Positioning System (GPS) signal accuracy for non-military users, was switched off. GPS, a multi-billion dollar space based positioning, navigation, and timing system established by the US Department of Defence and controlled by The U.S. National Executive Committee for Space-Based Positioning, Navigation, and Timing, then became a system in search of a new commercial market. Ben Russell commented that

hardware manufacturers seem to be producing devices that are as capable and open as possible, perhaps in the hope that users can tell them what the devices are for. In this sense, they seek grassroots and

consumer level interpretation of what these devices are as surely as they seek an answer from corporate users. [4]

LM can be thought of as a range of art practices which sought to reinterpret these emergent technologies as bottom-up rather than top-down technologies. [5] Ben Russell placed it squarely at the convergence of a rapidly unfurling technology and the social and physical spaces in which it is being deployed, describing it as:

a new site for old discussions about the relationship of consciousness to place and other people. A framework within which to actively engage with, critique, and shape a rapid set of technological developments. A context within which to explore new and old models of communication, community and exchange. [6]

It is this sense of a practice which seeks to engage, to shape and to set the agenda for location aware technologies which defines LM. I propose that this engagement takes it beyond a purely oppositional stance confronting what has been seen as the flaw in tactical media which "point out the problem, and then run away." [7] Through the introduction of novel practices and approaches toward technologies of location awareness, through questioning what this means and what it can mean, LM have in effect become involved in a process of shaping these emerging technologies. Lisa Parks in "Cultures in Orbit" asks "how might Western controlled satellite technologies be appropriated and used in the interests of a wider range of social formations?". Locative media offers one response.

Practices

I posit that this is due to locative media's influence on both the ways in which locative technologies are employed in an increasing range of everyday situations and fundamentally the way we think about and understand these technologies. This can be attributed to the set of user practices introduced by LM which shifted the meaning of these technologies through the privileging of user-centric modes of operation focusing on space as Lefebvrian lived space.

What do I mean when I speak of practice? At one level it can be thought of as the ways in which users engage with technology, the usage modes and habits which grow up around new technologies. [8] On a deeper level it is the ways that the technologies are integrated into everyday life which makes them meaningful and therefore useful. Paul Dourish sees the concept of practice as "one that unites action and meaning" describing "how the world reveals itself to us as one that is meaningful for particular sorts of actions". He continues "part of what people are doing when they adopt and adapt technologies, incorporating them into their own work, is creating and communicating new meanings through those technologies as their working practices evolve." [9] Crucially this process of making technologies meaningful comes through practice, it is not inherent in the technology nor can it be inscribed by designers being rather contingent on real world situations and revealed through practice. [10] The integration of new technologies into the everyday is dependent according to this account on a "supervening social necessity". Regardless of how innovative they are, technologies will not be adopted if they cannot be made to be meaningful in the context of the everyday.

The emphasis here is on what people actually do rather than what they are expected to do or are instructed to do. This can be described as tactical where "the imposed knowledge and symbolisms become objects manipulated by practitioners who have not produced them," [11] a form of resistance or

subversion. Or in a less oppositional sense as simply part of a "process by which we can experience the world and our engagement with it as meaningful" [12]. In effect it is to be expected that practices can be both, acts of resistance and pragmatic acts of appropriative assimilation.

The corollary is that practices which add meaning to a technology have the power to reposition the technology from the original intent of its creators, hastening its acceptance through shaping the technology. My proposal is that the work that LM has done in this regard is at two levels; one it has established a set of practices for engaging with location-awareness, with GPS and other location technologies and with the networked devices that are enabled by them and secondly it has caused us to think about location differently, in effect acting to "recode relations." [13]

The first consumer orientated applications of locative technologies which achieved broad appeal were satnav devices, direct descendants of their military antecedents in their approach to position. They orientated around position as points on the Cartesian grid identified by co-ordinates of longitude and latitude with the connection between the satnav unit and GPS satellites ever present. Of course this makes sense in an application designed for navigation, up to a point. As satnav gained a wider user base and became part of everyday situations so too did the anecdotal and media reports of its shortcomings. The familiar accounts of mishaps attributed variously to an over reliance on fallible technology but more cogently to an inability of the technological practices to account for real contingent local conditions. While satnav still has a niche the focus of development for location aware technologies and associated applications has shifted to mobile devices and applications which have a very different character focusing on exploring the individual's relationship with her location and augmenting that experience in a meaningful way. In short drawing substantially on locative media practitioners ambitions for these technologies and their articulation of location as Lefebvrian "lived space."

Position vs. Location

LM's articulation of location as lived space as distinct from the cartesianism of position is central to its approach. Position treats space as points on a cartesian grid identified by co-ordinates of longitude and latitude to be tracked and targeted with locative technologies ; for example as I write this at home an app on my iPhone locates me at 53°17' 22.74" N latitude, -6°8' 15.26" W longitude. Useful information if I were lost at sea, to or to be targeted by a Predator drone but it provides no information about the nature of this place, its history and the layers of association which constitute my relationship with it. In short it fails to address location as lived space and in doing so fails to build on the potential of the technology to enhance space. Location on the other hand is an "existential, inhabited, experienced and lived place," [14] the space of individuals and communities replete with histories, narratives and layers of association which imbue location with meaning which can be revealed and made visible through the application of locative media. I suggest that locative media's privileging of lived space and development of a rich set of practices building on the affordances of the technologies have introduced new thinking about location and the use of location aware devices.

Tracing Influence: The Afterglow of LM

There is much to be gained in tracing the trajectory of location-aware technologies and their public acceptance from the early GPS-centric satnav to today's smartphone apps and to unpack the nuanced but nonetheless significant differences in how they think about location and place. If location awareness is to be the nexus of mobile internet and the geospatial web then it assumes a pivotal role in the unfolding

of these technologies and their integration into the everyday. It follows then that for location awareness the practices which grow up around them are a critical contested space for the future of digitally mediated space. This fact is recognised in the ambitions of locative media practitioners.

I propose that the practices employed by LBS, particularly those which potentially have a wide user base like Facebook Places or which capture the popular imagination like Foursquare, are the agents involved in shifting the balance of these technologies from control space to enhanced space. If we follow the short trajectory of locative technologies as they move from new technologies addressing specialist user groups of military, mariners and surveyors to their current position as emerging technologies tentatively reaching a broader constituency of everyday users employing a burgeoning constellation of devices and applications we find a commensurate shift in the meaning of location-awareness.

Locative media practitioners operate within this window developing practices which are sometimes experimental and other times eminently practical which establish a mode of operating for location aware technologies which, if successful, remain permanently inscribed. Through augmenting space with location specific narratives, personal annotation, through revealing hidden histories, ludically transforming everyday space into digitally mediated game-space and developing proximity based social networking it can be said that LM projects foreshadowed all of the key areas of current location aware applications and services. Space doesn't permit a comprehensive detailing of these so I will outline a few examples each indicative of an approach shared by a number of LM works.

Consider "Urban Tapestries" (UT) the 2002-2004 research project which used location aware mobile devices to allow users to virtually annotate physical space to be asynchronously accessed by others in the locations to which they referred. The project established a rich set of practices which were researched, tested and refined. Envisaged as a public authoring platform UT consciously adopted a position as a counterpoint to what they saw as the "unnecessarily impoverished" prevailing views of the application of location aware technologies seeking to instead find out what it was about local places that mattered to people as they went about their daily routines.

True daily life is richer and more complex than the traditional view, relying as much on social networks, personal experiences, and chance interactions and connections, so pervasive computing applications should attempt to reflect this. [3]

Indeed this could be the mission statement for so many location aware mobile applications. Apps such as Color, Local Mind, Ditto, Whatser, Weddar, Foursquare, Gowalla, GraffitiGeo, SCVNGR, Yelp and Dopplr among many more share the concept of location as a social space defined by relationships and communities of interest through providing user tools for virtually annotating space. Building on the facility to quickly and accurately locate users mobile devices their focus is on location as lived space employing varying approaches and exhibiting an ambition to enhance space through fostering and building location based connections between individuals.

Similarly the practices of urban gaming, the ludic transformation of urban space mediated by mobile devices, introduced in LM projects such as Pacmanhattan and Blast Theory's Mixed-Reality games have pervaded LBS such as Foursquare and SCVNGR which incorporate game elements as well as location-based games such as Gbanga and AR games like Battle:Los Angeles. Proximity sensing familiar from LM works such as "Umbrella.net" (Brucker-Cohen, Moriwaki 2004) and "Aura" (Symons 2004), has become one of the fastest growing areas for LBS with the dating/contact apps of Gaydar, Grindr, Skout and

Whoshere standing out in a crowded marketplace. LM projects which overlaid physical spaces with narrative and sound such as "Trace" (1999), "Murmur" (2003), "34w118n" (2004) and "Media Portrait of the Liberties" (2004) have established a genre of their own with any number of location based heritage applications and commercially available apps such as those produced by companies like SoundWalks.

All Changed, Changed Utterly?

It is important to not overstate the extent of locative media's influence on location aware technologies or understate the challenges presented by the influx of development money as they enter the mainstream. These changes are incremental changes which insinuate themselves into the logic of the technology through introducing practices and ways of operating which are assimilated. They are however persistent, shifting user understanding of the technology which in turn impacts on the nature of development employing the technology. This is a process being continually renewed and challenged as new location-aware technologies emerge.

This does not necessarily result in a loss of agency for LM artworks. As illustrated by this author's 2010 "NAMALand" an augmented-reality app which overlaid Dublin with a layer detailing patterns of property ownership associated with the Irish banking bailout. The project was a popular success becoming part of the national debate on the financial collapse. From the perspective of our argument here it permanently connected emerging AR technology with activist political critique. There is a sense in LM practice that the introduction of user-centric practices responding to real needs can and have shaped the trajectory. This is backed up by a realisation that as location-aware technologies become part of the everyday they "might have been otherwise." [15]

Conclusions

It is my contention that the engagement of locative media artists with location aware technologies has changed their application in a range of everyday situations and shifted concepts of location from a GPS-inspired instrumentalised vision of positioning to a richer user-centric conceptualisation as lived space. These changes are reflected in an ever increasing range of mobile applications and services. This does not necessarily mean that Locative Media per se needs to continue, Locative Media represents a mode of engagement which will evolve with the technology. This mode of engagement, in whatever form it may take, will continue to have agency in shaping locative technologies as bottom-up rather than top-down.

BODY AND MIND: A 3D CGI ARTIST'S APPROACH TO MRI VISUALIZATION

JOHN MCGHEE

This paper discusses the author's practice-led approach and philosophical perspective to creating images that combine Magnetic Resonance Imaging (MRI) data with interpretative 3D CGI techniques. The paper concludes that more approaches to MRI data visualization could provide an aesthetic language that offers an alternative mode of interaction.

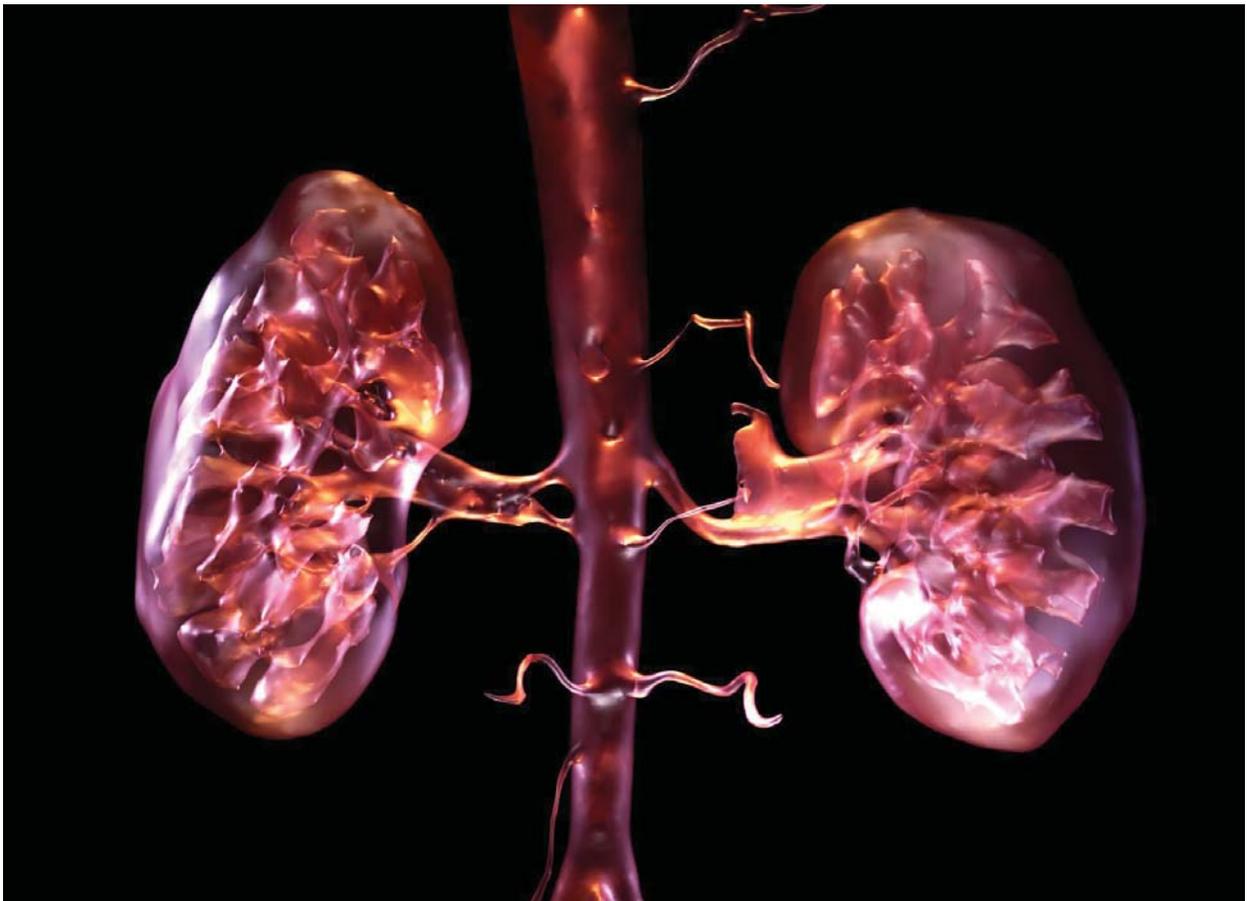

Fig 1. Kidneys. Copyright John McGhee.

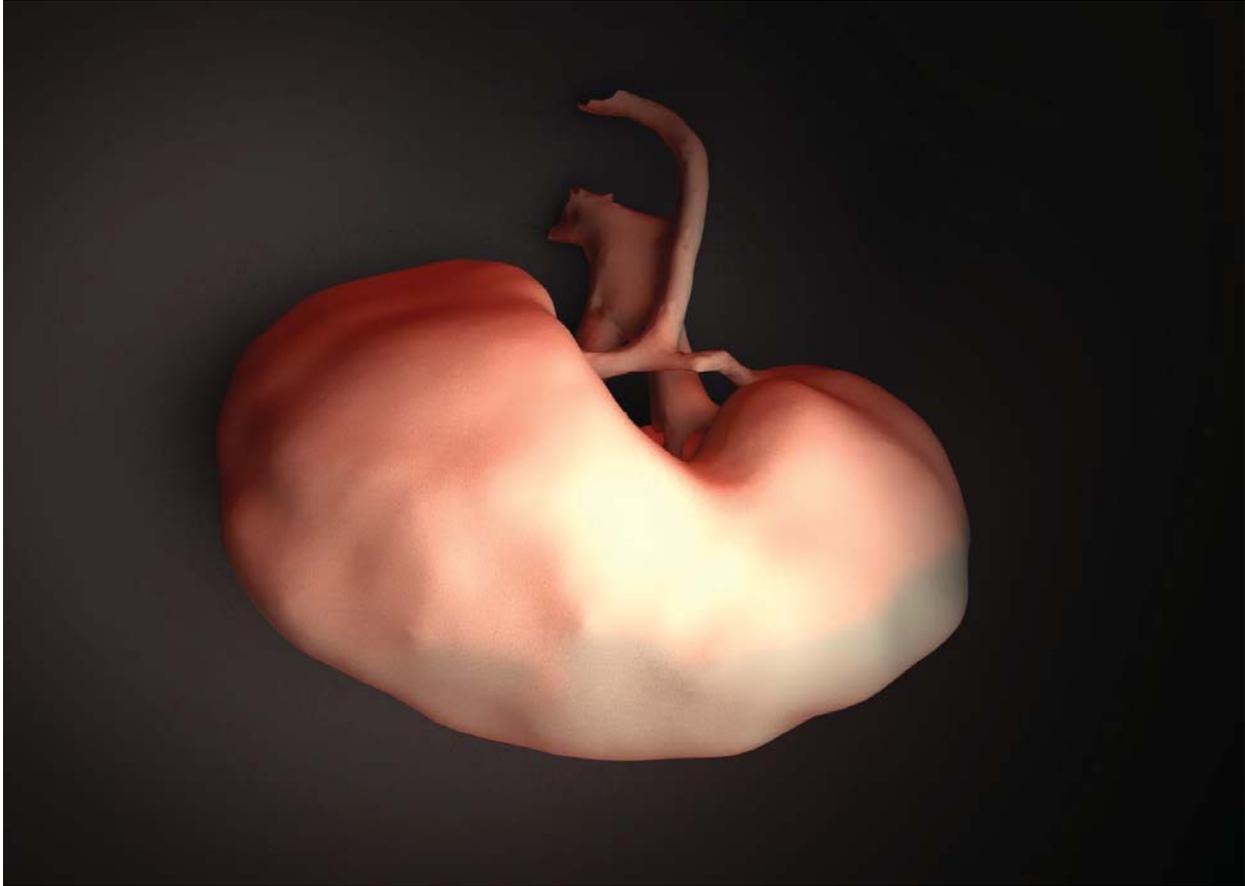

Fig 2. Isolation. Copyright John McGhee.

Introduction

Clinical imaging modalities such as Magnetic Resonance Imaging (MRI) allow the healthcare professional to explore, research and visualize our internal body structure. However the raw image data can be difficult to understand and interpret by the lay viewer. 3D CGI artists and researchers have the toolkit to widen accessibility to this type of image data.

In previous research work, the author established a pipeline in Mimics software to combine clinical MRI datasets with 3D Animation software Autodesk Maya (McGhee, 2010). Mimics is a package that facilitates the thresholding, segmentation and 3D meshing required for making MRI or CT into a surface http://www.materialise.com/mimics/main_ENG.html. The initial purpose of creating this hybrid approach was to develop 3D vascular images to improve patient understanding and comprehension of their vascular disease. This raises a series of philosophical questions and choices for 3D CGI artists; what is our role in creating these hybrid images? Do we act as a translator? Or should we mediate the data? In this paper the author argues that artists operating in this domain should provide new perspectives on

the data and not solely act as a conduit for scientific image dissemination. This, the author also argues is particularly relevant when stimulating dialogue between patients and health professionals.

1.0 The context

The role of the artist as scientific illustrator prevails in western medicine and has done for many centuries, whereby the artist is commissioned to illustrate for his or her scientific patron. This historical progression can be studied in germane research such as; 'Human Anatomy: Depicting the Body from the Renaissance to Today' (Rifkin et al., 2006). This type of medical anthology identifies the significant historical landmarks in medical illustration, highlighting the evolving role of the medical illustrator and placing the author's practice and research within an historical context.

Contemporary 3D computer-based animation in the field of biomedicine is a continuation of this historical timeline, providing screen-based tools to illustrate the internal body. According to Dijck (Dijck, 2005), computer 3D animation and visualization has provided artists with the apparatus to 'mediate' the human body with imagery. This 'mediated' perception as described by Dijck, has advanced into the digital age with both science and medical illustration using computer tools to virtually recreate and visualize the body. In the article 'Picture this' in the journal 'Nature' (Gewin, 2005), the medical writer Virginia Gewin identifies computer animation in biomedical science as a 'New-wave' niche. While this notion of 'niche' could be partly true, there is evidence to suggest 3D computer animation and visualization by medical artists is fairly widespread.

In Mike De La Flor's 'The digital biomedical illustration handbook' (De La Flor, 2004) several biomedical areas are cited where 3D computer graphics are applied. These include: 'surgical explanation, medical-legal, veterinary, patient education and cellular illustration'. In 'The Guild Handbook for Scientific Illustration' (Hodges, 2003), we also see evidence of the trend to move from traditional 2D methods of illustration to 3D computer animation, with an article by Mathews and Winkleman (Hodges, 2003) setting out a list of tools, materials and techniques for the 3D computer based illustration of science.

The medical animation firm Hybrid Medical Animation (Hybrid, 2010) demonstrates this emerging style. This model of production involves computer animators and artists being hired to construct a narrative to communicate a complex medical condition, a surgical procedure or the latest drug therapy. Further examples of commercial companies adopting this model include Biodigital Systems, Primal Pictures, Eye-maginations, Random42, Nucleusinc and Zygote to name but a few. However, these commercial examples often utilise edutainment as a mechanism of imparting complex biomedical information to the viewer. Edutainment mostly offers a stylised version of human anatomy and disease.

2.0 Clinical imaging aesthetic

In contrast to the 3D computer animation approaches discussed, clinical imaging refers to the acquisition of medical data, gathered from Computed Tomography (CT), MRI, Ultrasound and Positron Emission Tomography (PET) equipment. These modalities of contemporary clinical imaging apply a non-visible spectrum (radio waves and X-rays) to capture cross-sectional image slices of the human body. The term 3D medical visualization is a reference to the post-processing of this medical data acquired during scan procedure.

Medical interpretation of the body is but one stream of visualization, representing the body using a set of protocols and attributes embedded in science e.g. MRI. Radiological instrumentation describes disease in the language of science; abstract, specialist and separated from the body. In effect these images are encoded for interpretation by clinical radiologists only.

In this research the artist worked with cross-sectional MRI data of the human aorta, renal arteries and kidneys. The imagery captured by scientific instrumentation was a representation of inner body space. It is not truly a rendering of anatomy, but a translation of the body by the reactions of the tissues to the magnetic field of the scanner.

These types of radiological imagery attempt to break the body into pieces thus reducing it to understandable components, in the spirit of true reductionism. Empirical science sees the 'body as machine' a concept put forward by Descartes and Bacon and which still underpins the dominant reductive paradigm in medicine. Rosen argues: '...science is currently locked in the grip of a Cartesian tradition that asserts that organism is machine' (Rosen, 2000 p.297).

Established 3D clinical visualization in medicine is designed as a tool to support medical professionals in diagnosis, planning and training. It is a machine-based reductive form of instrumentation that is controlled, with interpretation minimised. This type of MRI imagery is absent of style, is based on reductive values and automated scientific protocols. The 3D visualization of data has some interpretation applied but is an automated and measured process, designed to minimise human intervention.

While the acquisition and visualization of MRI data generates an image that is difficult to understand for the lay viewer, it collects unsurpassed detail of internal body tissue. The medical gaze of MRI sees deep

into the body, exposing what would be 'invisible' to the visible spectrum. This clarity of vision and verifying of data, while encoded, could potentially inform and take the lay viewer to places previously unseen and unexplored. In comparison to the more interpretative approaches seen in 3D CGI biomedical animation, clinical imaging modalities offer the scientific clarity and detail that is difficult for the 3D CGI artist to achieve on his or her own.

3.0 Arts-based interpretation of clinical (radiological) data

There are individual artists who do not conform to the artist-as-illustrator of science model, and represent an alternative perspective. These visual practitioners go beyond the current notions of visualization and representation of MRI data, albeit using predominantly physical media. These individual artists are not necessarily concerned with communicating functional aspects of the inner body. The work they produce is not intended for clinical or diagnostic purposes, but for providing an alternative way of viewing the inner body for exposition. Sian Ede, the author of 'Science and Art' describes this approach as beyond the didactic: 'Artists don't 'do' prettification, product or propaganda for public understanding of science. But they can engage with it and create images, which suggest alternative ways of seeing' (Ede, 2005 p.3)

Ede discusses this reflective and experiential aspect of artistic thinking: 'If art is 'about' anything, it is a reflection of human experience in complexity and it emanates from an inventive individual with an unusual and sideways view on things, communicating with vigorous, visual acuity and daring, its intellectual content.' (Ede, 2005 p.3). The role of the artist as described by Ede cannot just be about producing imagery for 'product or propaganda for [the] public understanding of science'. Ede suggests that artists have a responsibility to produce images and artefacts that present an alternative way of seeing the world.

In the work of individual international artists such as Justine Cooper, Angela Palmer, Susan Aldworth and Jane Prophet we see an interpretative approach to describing the inner body. These artists use medical scan data to challenge and explore our perceptions of the body, as exposed by clinical imaging. While these individual artists offer 'alternative ways of seeing' their respective approaches are often more about their own personal statements and creative agendas.

In a clinical context, this artist-centric approach could be seen as inappropriate, with the space for self-expression and ambiguity being redundant in diagnosis. However, to merely produce imagery that serves science would contribute little to the field and inevitably dilute the artist's contribution.

There is evidence to suggest that purely scientific didactic approaches to disease explanation may not be the best suited approach in patient communication. Cecil Helman in his book 'Culture, Health and Illness' (Helman, 2001), describes the communication problems that currently exist in the field of doctor-patient interaction. In particular, the notion of mind and body separation is significant, as it situates disease in the context of mechanics, separate from the mind. Illness is defined by 'objectively demonstrable physical changes in the body's structure or function which can be quantified by reference to 'normal' physiological measurements.' (Helman, 2001 p.80). Medicine concerns itself only with abnormalities of the body, viewing 'physical abnormalities' as opposed to a 'patient's symptoms, their psychological state, or cultural background' (Helman, 2001 p.81). If we are to connect with patients more holistically, I would argue that utilising new visual approaches and creating images that reconnect body and mind are advantageous.

4.0 The author's visual practice: the hybrid approach

The various pathways discussed in this paper all have merit as a means of engaging differing types of audiences using screen-based media. The author proposes that the blending and combining of these modes of visualization can result in an alternative pathway for visualising medical scan data. By mixing the strengths of clinical data and 3D CGI arts based interpretation, a series of 3D CGI artefacts emerge that could facilitate a new mode of interaction. This paper briefly discusses some examples of the author's approach.

1) THE KIDNEYS - WIREFRAME EXPLORATION

Once the data is extracted from the MRI dataset, the artist is left with a 3D model of the anatomy, containing none of the colour and lighting present within real life photographic situations. This provides a mechanism for interaction, displaying a digital model in real-time. In these wire-frame renderings, I can tumble through, around and inside the 3D mesh. This familiarisation process provides me with a means of exploring the complexity of the anatomical form, as well as stimulating ideas for visual narrative and aesthetic.

This type of image is not meant as a fully rendered final shot, but provides a digital sketchbook for exploring form and composition. The image files provide me with a window into the body, although not necessarily an understanding of the body.

II) THE KIDNEYS

The intention of adding digital lighting and colour to the wire-frame model is not to inform the viewer of the mechanical processes involved in blood filtration, but to start to develop an aesthetic language for communication. Using CGI lighting, a visual quality is applied that renders the image more like glass than soft organic tissue (Figure 1 - Kidneys). The transparency used in the render of this image provides a simulated optical effect that shows a structure within a structure. This aesthetic style translates the human kidneys into a screen based digital artefact with an alternative approach to the reductive.

In a separate piece of work a virtual camera was placed inside the aorta. A cave-like interior starts to emerge from the data, as the model is rotated and digitally surveyed. This suggests a feeling of isolation within a very large passageway or tunnel that winds its way through the human body. This stepping inside the aorta enabled me to explore yet another engaging structure, within an overarching complex form. By placing the viewer inside the structure, a sense of audience participation is introduced, challenging the viewer to explore this vast space further.

III) ISOLATION

The inner human body is completely devoid of daylight. It is a space that functions in constant darkness, only ever illuminated by the non-visible spectrum of MRI and X-rays.

Building on further exploration from the same dataset, a single kidney was isolated from the rest of the form. The kidney was rendered using a more diffuse and scattered lighting technique (Figure 2 - Isolation). The form takes on an almost foetal like position with a warmth to the surface. The essence of this image is to convey the sculptural form of the human kidney, isolated from the body.

5.0 Concluding remarks

This paper puts forward the idea that 3D CGI artists can combine clinical MRI data with a more arts-based approach. The goal of this combined approach is to develop a new visual aesthetic. The application of this type of work transcends the gallery space, offering digital imagery that could stimulate dialogue between health professionals and patients; an impartment of information beyond the purely functional.

It could be argued that this is not a new approach. The early anatomists saw this philosophical stance as the norm. The Renaissance humanist and Professor of Anatomy at University of Padua, Andreas Vesalius

(1514-64) published seminal work, entitled 'De Humani Corporis Fabrica Libri Septem' (The Fabric of the Human Body in Seven Books) (Vesalius, 1543). This provided the first detailed published anatomy book in western medicine. Vesalius believed in the humanist notion that images embody an idea and offer meaning beyond words. This work revisits this approach, in developing a contemporary visual language for potentially improved patient interaction and communication.

ANIMATED GRAPHIC NOTATION

Shane Mc Kenna

This paper discusses the authors' use of animated graphic notation to encourage collaborative music making for a wide range of performers with different musical backgrounds. In terms of notational reform this essay will ask two important questions with reference to the author's work: What are the problems with the old notation, both traditional and static graphic notation, and what is useful about new forms of animated notation.

Fig. 1 - Combination of audience and instrumental notation.

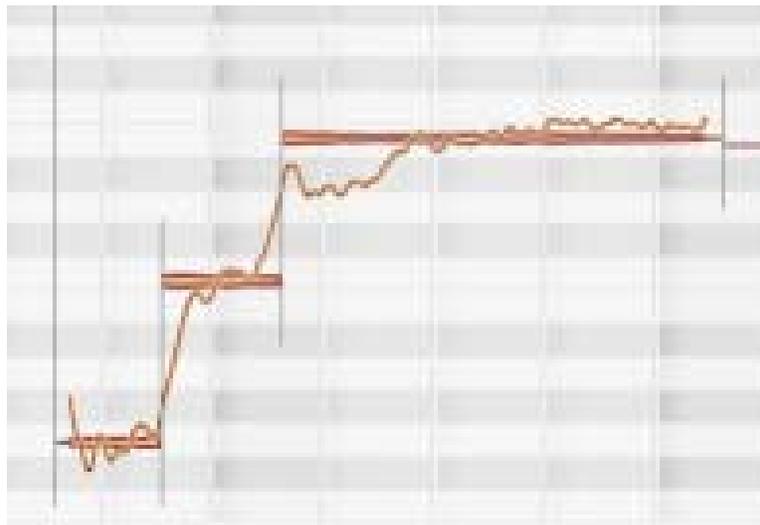

Fig. 2 - View of Melodyne with pitch shown on the vertical plane and time on the horizontal plane.

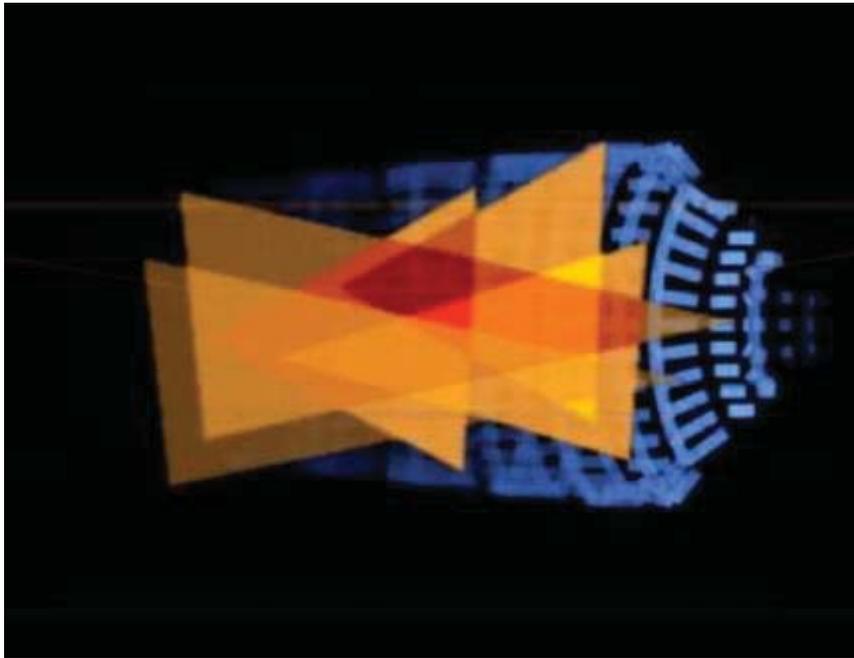

Fig. 3 - Notation for orchestra

Origins and Motivation

As a music maker and music teacher the main aim of my work has been to create genuinely accessible musical experiences, which invite participation based not on musical experience or training but on a simple willingness to take part. This approach arises from the view that music is a fundamental human activity, which forms a part of all known human cultures past and present [1] and which not only satisfies our creative urges but plays an important role in our personal and social development just as it has in our evolution and survival [2] as a way of promoting cohesion through collaborative experience. In western art music the development of notation lead to a gulf between those who take part in music - performers and composers - and those who simply listen - their audience. This has been reinforced by a music education system which concentrates largely on music and notation of the past without giving due attention to the development of musical ideas in contemporary music and to notational reform. The use of graphic notation in education has been shown to encourage creative thinking, collaboration and ensemble performance, while also dealing with general musical concepts, which apply across many genres and styles of music. [3] From my own experience of using graphic notation in the classroom, and as a compositional device I began to develop a system of animated notation, which would further serve the idea of creative collaboration and accessible music making.

Notation – The Western Tradition

Conventional music notation represents a system of communication between composer and performer which has been the basis of musical creation in the western world for hundreds of years. The writings of Guido of Arezzo from the eleventh century reveal that notation was used to record and preserve music and to provide performers with a memory aid to assist performance. [4] In *Micrologus* (ca. 1025-28), which drew on the theoretical studies of the ninth century, *Musica enchiriadis* and *Scolica enchiriadis*,

we also see the development of a fixed system of notation giving rise to the study of music as a theoretical language. With the refinement of this notation came the opportunity for composers to create polyphonic works for a number of musicians reading independent parts, replacing the single line melodies sung in unison, which had previously dominated. These developments allowed for the thoughtful organisation of music, which calculated the effect in advance of the performance and provided an exact timetable for the coordination of different parts. An in-depth knowledge of notation, and the musical theory needed to decipher it, became a pre-requisite for becoming a musician and certainly for becoming a composer. A hierarchical structure developed in western art music with the composer instructing the performer for the benefit of the listener, creating a situation where all of the musically uneducated can listen, few can perform and even fewer compose. If we consider listening to be the most vital and beneficial part of the musical experience then this system is justified. If we consider participation in music making to be the most vital aspect, then this system must be questioned.

Animated Graphic Notation

The evolution of graphic notation in the 1950s was, in part, due to the perceived failure of conventional notation to adequately represent the growing range of sounds and performance techniques being explored by some of the more innovative composers. In the 1920s work like *Hyperism* and *Ionisation*, by Edgar Varèse, liberated composition from melody, harmony, rhythm and regular pulse, ideas easily represented using conventional notation. The growing use of unpitched, non-western instruments and electronic sounds exposed the limitations of notation to accurately represent these imaginary sound worlds to be produced in live performance. Graphic notation allowed composers to create musical scores which would represent their ideas but which needed the collaboration of the musicians to produce the desired sounds. This implies a new composer/performer relationship, where the composer relinquishes some control over the resulting sound, alternatively trusting the musical instincts of the performer. The focus of the score now shifts from being an accurate timeline of sound events, which the musicians must produce, to a communication of a musical idea to be interpreted.

One of the great advantages of conventional notation is the control it offers the composer over durations within a piece. With the help of trained performers, composers can create rhythmically complex works with large ensembles, where every detail of the musical timeline is precisely arranged in advance. This is only achievable after establishing conventions of rhythmic notation as standard amongst composers and performers. With static graphic notation, the lack of objective rhythmic conventions often leads to both indefinite rhythm and unknown duration of many graphical pieces. Animate graphic notation allows for intuitive and clear cues for durations and for dividing sections of an ensemble using visual parameters, like colour and position on screen and although it is difficult to emulate the precise rhythmic nature of conventional notation, visual rhythms can be easily used to indicate pulse leaving the precise rhythmic interpretation up to the performer. Much of my work, which will be discussed later, chooses to leave the final decisions of rhythm, pitch and timbre to the performers with the notation designed to supply enough information to communicate a musical idea without specifying a musical sound. This type of animated notation allows each score to be accessible to a wide range of performers, with different levels of musical experience, and to be open to different interpretations from ensembles of all sizes.

Research, Performances and Installations

In April 2008, two experimental electronic artists, one cellist with a looped effects unit, a classical trombonist and clarinet player, a number of percussionists and around forty audience participants as vocalists, took part in my first experiment with animated graphic notation for a large ensemble in The Bernard Shaw venue in Dublin. None of the performers had seen the score before the performance so the ensemble was divided into three sections: the vocalists followed the white parts (mainly letters like 's' and 't', for texture and percussive sounds); the acoustic instrumentalists followed the blue yellow and orange sections: and the electronic performers interpreted the background video elements (Fig. 1). The notation for *The Score* in the Bernard Shaw resulted from a number of months of experimentation with simple animated shapes and video footage mostly concerned with changing scale and visual rhythms and the use of colour to divide up sections of an ensemble. The performance worked extremely well as an example of collaborative music making with an ensemble of performers who hadn't rehearsed, many of whom were not familiar with graphic notation. The diverse range of performers working closely together as part of a spontaneous musical experience was the most encouraging part of this early experiment and much of the notation used here was adapted in the next stage of research, involving a more scientific approach.

The next step was to create an installation piece which invited people to give a vocal interpretation of a short animated graphic score, each in isolation and without hearing the other participants' interpretation. A mixture of participants with different levels of musical experience were chosen; from professional classical musicians to participants with no musical training. Their interpretations were recorded, analysed and used to create a layered backing track for a live multimedia performance in 2008 entitled *Three Streams*, a piece that used the same animated notation interpreted by trombone, cello and percussion. The score for the installation was divided into a series of animated shapes and symbols, which repeated three times. The first two were a line of 's' and 't' shapes moving across the screen used as an example of socially learned symbols which are easily interpreted as vocal sounds. The symbols and shapes gradually became more abstract and with more complex movement in order to explore the instant oral response to the visual parameters of changing scale, movement, texture and position (in relation to screen position and to other symbols). These visual parameters were expected to influence the dynamics, duration, timbre and pitch of each interpretation.

Great lengths were taken to animate each part of the notation in a way which could be instantly interpreted by using changes in opacity (fading in and out) and screen position to mimic the forward reading that takes place when a musician sight-reads conventional notation. When sight-reading the brain does not simultaneously absorb individual pieces of visual information, process it and control the motor functions that make the sound. Instead, the reader takes in large amounts of information within the visual field in what are called fixations. [5] Each fixation involves looking forward but also looking backwards (regression or backwards fixation) which is represented by fade in and fade out in this system of this animated graphic notation. The analysis of the recordings, which included forty individuals, showed similarities not only in the interpretation of socially learned symbols like letters but also in the response to abstract shapes. Similarities in participant's pitch, duration and even timbre suggest that certain visual parameters are objectively linked to sounds and that a common musical language exists between the participants, which may be socially learned but is not a product of musical training. A notable feature of these vocal interpretations was the lack of discrete pitches used throughout, with a complex combination of sliding pitches more common, making it difficult to analyse the exact pitches used (Fig. 2). The performance, which followed the installation, was a combination of the layered installation recordings with live interpretation of an extended score. This was projected for the

musicians and the audience, many of whom had participated in the installation, providing an intimate insight into the performance and composition of the piece.

Pulsing Shapes Colours

My 2009 piece *Pulsing Shapes Colours* was created to explore the use of animated graphic notation to create a spontaneous performance for orchestra introducing each section separately, with each following a different colour, but with a combined sense of pulse drawn from visual rhythms. No member of the orchestra had previously seen the score so the notation was designed to be easily sight-read using a small number of repetitive pulsing shapes, which fade in and out over eight minutes. Each one of these shapes contains both a simple pulsing rhythm and complex inner rhythms, which may be interpreted in different ways (Fig. 3). This was designed to keep the individual performers and each section linked into a common pulse while allowing them the freedom to explore different rhythms, from the visual rhythms on screen or from listening and mimicking each other. Each section of the orchestra was given a different part of the score to follow: The piece begins with brass and upper strings, followed by lower strings responding to any red parts of the score and woodwind following the red/orange section. The percussion were given free reign to pick up on any interesting rhythmic parts they saw on screen or heard from the rest of the orchestra. No performance instructions concerning pitch, performance techniques, rhythm, timbre or dynamics were given. The members of the orchestra, who had been chosen through audition as the most highly accomplished musicians of their age in Ireland, seemed to relish the chance to perform freely without the level of instruction and direction they were normally accustomed to. Yet as soon as the lights went down and the animation began – which was projected onto a huge 20ft screen – they became immersed in a new musical experience where they were given the freedom and the combined responsibility for shaping the sound of the piece. The orchestra continued playing for ten minutes after the piece had finished, taking advantage of the opportunity to explore orchestral sounds in a spontaneous and improvised manner.

Three For Four

Three for Four was created for the Irish Composer Collective and performed in Sonic Arts Research Centre, Belfast and the National Concert Hall, Dublin. The piece uses just three simple shapes: lines, circles and triangles, in four colours moving in different ways. This piece was originally created for string quartet and was performed as part of a concert with a traditional audience/performer setting, with the exception that the performers were positioned side-on to the projection on stage so they and the audience could see the score clearly. Although in this type of concert the audience is not directly involved in the music in terms of performance, they are given an insight into the piece through the projected score. As was suggested in the installation piece for *Three Streams* a subjective connection between certain moving shapes and symbols exist so that the audience can understand the interpretations of the performers. *Three for Four* was also used to explore the versatility of animated graphic scores by recording a number of different interpretations from different groups including New Dublin Voices (a thirty-piece choir) and jazz pianist Johnny Taylor. Each section of the choir – soprano, alto, tenor and bass – followed a different color while Johnny Taylor recorded a separate layer for each colour, working within a loose harmonic progression for different sections and assigning certain themes and motifs to shapes and colours. Each of the three interpretations were used in an interactive installation where the score was repeated on a loop and the passing audience members could use three faders to mix the recordings of the individual interpretations together. Although none of the groups heard the others interpretation and there was no discernable connections in choice of pitch in terms of

traditional harmony, the subjective connections between moving shapes and sounds create a relative movement of pitch, dynamics and duration which compliment each other in the same way the orchestra found a common sense of movement. The choir recording also had a strong connection to the recordings taken as part of the Three Streams installation. Although New Dublin Voices are a highly trained and experienced group of singers they rarely rested on discrete notes with their undulating pitch and rhythm showing many similarities to the individual *Three Streams* recordings.

Conclusions

Over four years of performances and recordings have shown that animated graphic notation is an effective way of creating a shared musical experience through creative collaboration. Over 200 performers have taken part in these pieces ranging from experienced noise artists, jazz and classical musicians to amateur musicians and participants with little or no musical training. The connections between all of these performances indicate an understanding and ability to create musical sounds, which use dynamics, pitch, durations and rhythms, that may be socially learned but appear not to be based on musical training. It is the role of music education to encourage and nurture this shared musicality for the benefit of the individual, the group and of musical culture in general. For composers and musicians, new notation presents opportunities for working in more collaborative, accessible and versatile ways, which encourage participation in musical activities beyond the listening experience. The advantages of using animated graphic notation to add structure, encourage creativity and provide a focus to ensemble performance makes it an important element of current notational reform.

TOWARDS CO-AUTHORING COMMUNITAS: CONSIDERING THE POTENTIAL OF DIGITAL ART PROJECTS WITHIN PLACE-MAKING AS A PROCESS OF BECOMING

Anita McKeown

Digital technology, particularly the internet, "a natural environment for liminality" (Waskul 2004,40) in conjunction with open source software / culture are considered as tools for the creation and production of liminal phases / liminoid spaces. Could such digitally produced spaces produce *communitas* and if harnessed within place-making, encourage a process of 'becoming' both for the project participants and place involved.

Aristotle's belief that humans were a mix of matter (constant) and form (constantly developing) contributed to his understanding that humans have an "innate capacity for action: to change the world to his or her whim (*techne*), the ability to move from sheer possibility to actuality." (Brommage 2005,11) This process of change from a lower level of potentiality to the higher level of actuality is known as becoming. Maslow referred to this process as self-actualisation, or to become more and more of what one is, or capable of becoming. Within Jungian psychoanalysis self-actualisation can only fully occur once the process of Individuation is complete.

Individuation is the transformational process of integrating the conscious with the personal and collective unconscious (Jung, 1962, p. 301). Through Jungian psychoanalysis, a period of reflection and transformation is undertaken during which, the essential personality of the person, their individuality can emerge. Jung believed this resulted in a profound healing effect on the person (Jung 1962, p. 433). This process often occurs within a particular context or setting separate from but in parallel with the mundane, everyday life of the individual, a context, which could be referred to as liminal.

The term Liminal derives from the Latin *limen*, or threshold and was first used by Arnold Van Gennep (1909 translated to English in 1960) in *Les rites de passage*.¹ Here Van Gennep discusses three stages that accompany the 'movement from one cosmic or social world to another' (Madge & O'Connor 2005, 93), separation (preliminal), transition (liminal) and reintegration (post liminal).

During the pre-liminal stage an initiate is separated from their usual social environment and what has been their way of life and its related beliefs to date. They then enter the liminal phase, which signifies for Van Gennep, a ritual space of transition. Here the initiate's pre-conceived ideas and beliefs are challenged through the extra-ordinary experience of initiation, followed by the post liminal phase. Within Van Gennep's rationale, during the post liminal phase the individual and their initiatory knowledge is re-integrated into the general society.

The anthropologist Victor Turner (1967) in his often-cited text 'The forest of symbols' picked up on Van Gennep's ideas and re-defined them within the context of 1960s counter culture to develop a new anthropological perspective on liminality. Turner, argued that in order for the process of becoming / self-actualisation to take place the dissolution of the normative values or understanding of one's self and

context is necessary (Turner 2008). For Turner, this dissolution, occurring during a liminal phase, although initially destabilising, could create an environment conducive to the individual's values and normal modes of behaviour being reflected upon and transformed.

For both Van Gennep and Turner the liminal state signifies a time of transition albeit manifesting differently, a 'time out of time' where one is 'betwixt and between' (Turner 1967,) not only social status but also social mores and beliefs. Where Van Gennep discusses the phases as part of a ritual process, Turner deviates, taking the idea of the liminal into secular contemporary societies; spaces he identifies as liminoid. Turner proposed (1982, 32) that liminal spaces could not be applied to 'modern societies' as they are for the most part secular. Liminoid spaces have similar qualities and functions but are not part of a spiritual or initiatory journey with no rite of passage. It is Turner's evolution of the liminal into liminoid, which holds fertile potential for digital arts practice to contribute to a process of becoming through the practice of place-making.

Place-making is a community-driven process of people making a place and strikes a balance between the physical, the social and what could even be considered spiritual qualities of a place. (PPS 2011). This process, returning to Aristotle's understanding could be re-considered as a process of becoming, 'moving from sheer potentiality to actuality'. If we employed digital media/technology as part of this process, this could also be an opportunity for self-actualisation. The creative use of digital media / technology could be used to deconstruct an understanding of a location, a reflective and transformative process by residents, which could manifest as an essential personality inherent within the location.

Turner when explaining the essence of liminality stated it was "found in the release from normal constraints" adding that; liminars were individuals who had the power to "reveal the freedom, the indeterminacy underlying all culturally constructed worlds, the free play of mankind's cognitive and imaginative capacities" (1969 161). Contemporary cultural theory reconsiders Turner's notion of limen or threshold within the notion of the border. Indeed it has been argued, (Rosaldo, Ortner et al) that Turner's vision is somewhat Utopian and in fact that rather than being re-integrated into the status quo the individual may in fact seek to change it. Turner identifies "Ritual Liminars or Edgemen" who "possess the 'radical potential of cultural critique, indeed of deconstruction,'" (Turner 1969, 128) yet for the most part Turner's ideas lean towards re-integration to society in a similar vein to Van Gennep.

Weber considers the liminal phase to be simultaneously "culturally dangerous but culturally creative," (1995, 526) a place of action. As the cultural beliefs are challenged and broken down any re-integration may include an inability to conform to the previous value system, yet this may in turn contribute to the creation of new systems.

Digital technology, particularly the Internet, "a natural environment for liminality" (Waskul 2004,40) and open source software / culture can be considered as tools for the creation and production of liminal phases / liminoid spaces where a constant cycle of de / re -construction takes place. Technologies often referred to as new / digital Media, in particular the Internet / cyberspace have as defined by Flew (2008) the following characteristics; they can be manipulated, are networkable, dense, compressible, interactive and are perceived at least, as immaterial. It is these qualities, that create the in-between or threshold states, reminiscent of the liminal phases Turner and Van Gennep referred to, the liminoid spaces that could be utilised within the the processes and practices of place-making.

Projects that use these technologies in particular the internet or cyberspace can be considered from this perspective of in-betweenness or threshold space as any activity undertaken cannot be separated from

our pre-liminal understandings or connection to our embodied experiences and practices. Whilst we can transcend the physical limitations of time and space momentarily, we enter this space from a corporeal position and always return to our corporeal world and all that entails.

Pratt 2002; Walmsley 2000 highlights this in noting that ‘communities and forums that exist online are still rooted in place and space whether that is a physical location or a space of shared interest, being human they can be rooted no other way. Whether as the creation of bits, the use of the Internet, either through social media, virtual worlds or simply searching for information, the virtual and corporeal are all part of the online virtual experience. We cannot separate from our physical world and the disruptions of presence / absence, mind / body on and offline are all part of this dualism.

This dual nature has social, cultural and political implications with geographers increasingly examining what Kitchin refers to as “the role of space and place in a distributed social space that lacks physicality” (1998a, 393). I propose that it is this very lack of a fixed physicality and the momentary transcendence or disruption of physical limitations that can be exploited for the deconstruction or undoing of understandings of place and a co-authoring of *communitas*. The identity of a place is not fixed, with individuals having a personal, subjective understanding of a place and knowledge that could be viewed as assets for change and evolution, personal and locational.

Turner’s relating of Van Gennep’s ideas to a secular contemporary world incorporated what Weber (1995, 527) calls “the shifting unfolding, processual, dynamic dimensions of cultural change: the shifting relations among liminality, *communitas*, and structure.” The dictionary definition of *communitas* refers to “an unstructured community in which people are equal’ or ‘the sense of sharing and intimacy that develops among persons who experience liminality as a group.” (dictionary.reference 2011) The etymology of the word stems from the Latin *communis*, meaning common or public and is therefore often used to denote a sense of community, public spirit or a willingness to serve one’s community. Turner distinguishes between three types of *communitas*; existential or spontaneous *communitas*, the transient personal experience of togetherness. Normative *communitas*, *communitas* organized into a permanent social system and ideological *communitas*, which can be applied to many utopian social models. (Turner 1969: 132)

A participatory digital art project’s potential to produce *communitas* can be considered from a number of perspectives in relation to Turner’s definitions. Firstly the life cycle of the project through the nature of shared experience and achievement offers an opportunity to develop existential or spontaneous *communitas*, which Turner and Van Gennep argue occurs within a liminal phase / space. The community of the project exists temporarily, although some longstanding relationships maybe established and extend beyond the lifetime of the project. If working well will evolve, “an equality of relations, a comradeship that transcends age, rank, kinship etc. and displays an intense community spirit. Thus people from all social groups may form strong bonds, free from structures that normally separate them.” (Madge and O’Connor 2005,93)

If the project is embedded within the practice of place-making then the process of *communitas* becomes one of collective power and production and the shared personal experience of the place-making could be a collective response then integrated into the processes of planning and regeneration. In this sense the inclusion within the system utilises the rules and power relations of the social structure simultaneously, to constrain and enable human agency as being closely involved in the reproduction. This would most closely resemble the post-liminal phase and if we think of communities as being based on

the shared experience of living in a location rather than more romantic notions then normative *communitas* is more easily identifiable. The concept of place-making as a process of becoming through the co-authorship of *communitas*, at once is more achievable if considered as the shift from the potential of the city and its inhabitants to a higher level of actuality.

For Turner (1967) the liminal phase was important as a 'threshold' space that held the potential for *communitas* given the intimacy and commonality of shared experience evolving through the liminal phase of an initiation or rite of passage. The rituals and activities undertaken within the liminal phase provide an experience of where the status quo appears to dissolve. Although initiates re-integrate into society their understanding has shifted. Using Turner's secular re-interpretation of Van Gennep's theories, digital art projects function as liminal phases / liminoid spaces through offering "time out of time" or Turner's concept of "betwixt and between" while being parallel to the everyday existence.

Digital art projects focussed towards the practice and process of place-making provide the time and space to represent more voices and experiences to expand residents' understandings of place and in turn disseminate this knowledge. Pred (1984) states the "character of unknowing in a place constrains the cultural and social projects that eventually may occur" therefore the importance of having new shared understanding of place, or knowing is necessary for the purpose of becoming and any shift from potential to actuality. Through experiencing this process, an intimate shared experience enables the participants of the project to explore different ideas and possibilities and ultimately create different solutions or outcomes for a location.

The 45s series, an on-going series of audio-visual projects, that exist both off and online and offer opportunities for continuous remixing, explore these ideas. Once the physical aspects of the project are complete (motion sensor installations, films, psycho-geographic workshops, projection events etc.) the films and audio mixes live on line with all the samples available for re-mixing. These common lands of digital data enable the contributors to create an on-going co-construction of the area through the virtual galleries and submitted portraits after the initial project is completed. This continues to encourage counterfactual re-presentations and conditions by a multitude of voices. Through the "posing of possibilities beyond what is assumed to be the case," Macleod 2005, the on-going project activities lead to a conscious re-fashioning of their 'place'.

The 'legacy' of the projects, a co-authored *communitas*, reflects and enshrines the community's self-directed, heterogeneous self-image. The 45s series enables the process of place-based learning and re-learning evolving an intimate relationship with place and in turn the location's other residents. Enough compatibility is generated to enable communication and a more expanded experience of place and ultimately learning. Through the intimacy created within the shared experience (*communitas*) of the project and the deconstruction / reconstruction that Turner refers to during liminal phases / liminoid space, a transformative process equitable to individuation "integrating the conscious with the personal and collective unconscious" can occur (Jung, 1962, p. 301).

This process reminiscent of Jung's process of individuation extends the *communitas* of the project through a process that potentially enables diverse groups made up of strangers, to interact with people whose opinions, values and culture are different. The project contains the group giving them enough commonality to begin to feel comfortable with their difference. These emerging relationships can then be capitalised to develop and evolve the places we live, conducive to our well-being with the legacies of the 45s projects include networking activities, campaigning forums and sustainable community activity.

Such persistent challenges to given understandings of place through the constant re-presentation of multiple identities and understandings, ultimately offers, processual re-tellings of the story of that place, the location of individually felt meanings and values expressed coherently as its personality and uniqueness – its individuality. Returning to Jungian psychoanalysis Jung believed that this process of reflection and transformation in which, the essential personality emerges has a profound healing effect. The liminoid spaces that are created through the digital art projects may offer a contemporary opportunity to undertake activities that within a secular existence to experience aspects of the liminal phases of ritual many no longer engage in.

Perhaps in the steps towards co-authoring *communitas* through the use of digital art projects within the process/practice of place-making, the places we reside and ourselves may undergo a process of becoming. In reaching a higher level of actuality, we may go some way towards fulfilling our potential, manifested and tangible in the places we make.

PLAY WITH FIRE | A REAL-TIME VIDEO EXPERIENCE FOR SUSTAINABILITY

Mónica Mendes, Nuno Correia, Valentina Nisi & Pedro Angelo

Play with Fire is an interactive art installation that proposes participants to ignite generative fires over live streaming video of selected forests. This experience paradoxically encourages playing with fire to stimulate awareness and prevention of fire related damages to the forests. Our goal is to raise awareness for human causes in forest fires and effect attitude change towards environmental protection.

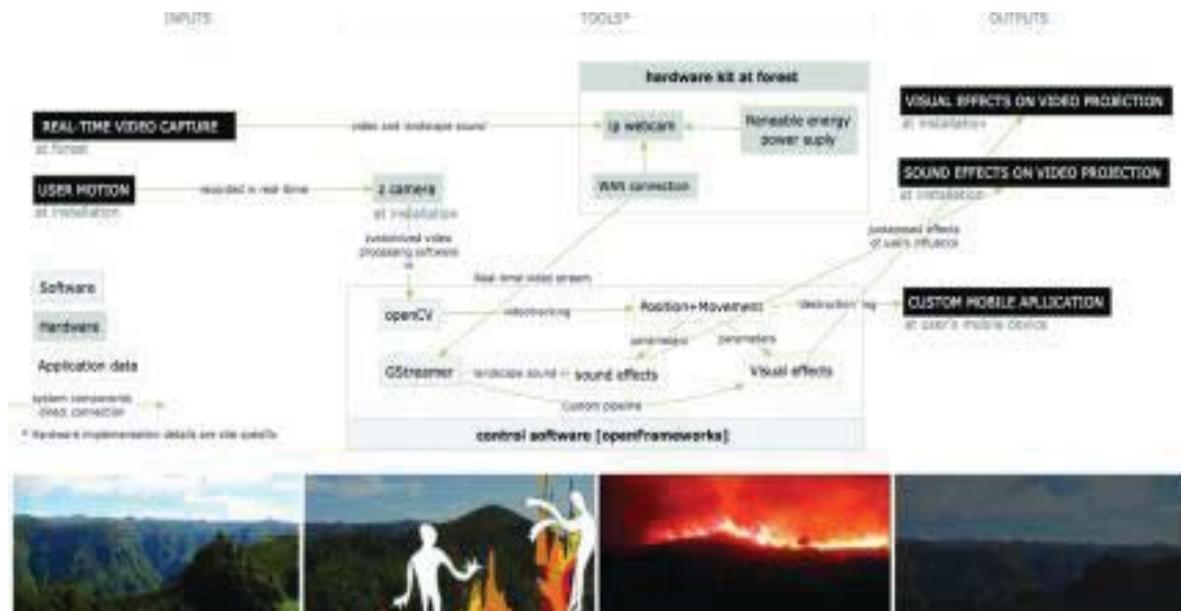

Fig 1. Play with Fire concept art and system architecture.

Fig 2. Sketches for the interactive installation, user experience and gestural interaction outdoors.

Fig 3. Task analysis testing the user experience.

Play with Fire is an exploratory research project that proposes an interactive installation to engage the audience senses in unconventional ways. It is a performative, immersive experience that invites people to interact with real-time video from selected forests by playing with virtual fires through gestural interaction.

We envisage the installation triggering controversial feelings by combining the "beauty and danger" of a forest on fire. This duality becomes part of the experience, and raises concerns in the audience mind, such as the pleasure and excitement of playing with fire versus its effects on a natural resource such as a forest. The experience concludes with visuals of a forest virtual regeneration process underlining the message: the forest will eventually grow again, but what is the price to pay?

In order to foster awareness and stimulate activism, we decided to conceive and design *Play with Fire* as a digital art experience that happens over three different moments: an introduction to the installation and its theme with an invitation to interact with it; the performative active part where the participant engages with the gestural interface, and a reflective part taking the form of a mobile application, which will stay with the participant for a long time after the installation experience.

An ARTiVIS experience

Play with Fire is part of ARTiVISS (Arts, Real-Time Video and Interactivity for Sustainability), an exploratory research in digital media related to sustainability [1].

At the intersection of Art, Science and Technology, the research engages a multidisciplinary team that follows a collaborative approach, where artistic practices are supported through technology. Regarding the impact and the potential of art and technology on society and the environment, we aim at creating a “forests showroom” experience through digital media, in order to inspire change in the lifestyle of the public. The outcomes of ARTiVIS include an online platform, interactive installations – Hug@ree, Treeelucinations, B-Wind!, Enchanted Forest, MAicro, and this *Play with Fire* experience – and the design of a DiY surveillance kit prototype.

MOTIVATION

Living in places that have always been extremely exposed to forest fires, makes us very sensitive to the destruction of the forest patrimony by fire hazards, which also applies to a world scale. This interactive experience paradoxically encourages playing with fire to stimulate awareness and prevention of fire related damages to the forests. Ultimately, we seek to pose a constructive approach to the destructive dynamics of fire that aggravate climate change. Can digital art foster awareness and respect for nature?

RELATED WORK

Play with Fire is a transdisciplinary project and, as such, requires a diversity of references. Involving digital media, the environment, and real-time video, this interactive experience congregates references from the Arts, Sciences, and Technology. The selected case studies presented in this section are examples that in some way inspire the concept, its features and future developments.

Climate change and surveillance are very relevant and currently discussed topics in the areas of digital art and design. The role and potential of design research in the transition towards sustainability is being discussed in mainstream design and digital media art events, such as “Repair” and “Goodbye Privacy” at *Ars Electronica*, *Changing the Change* [2], and *Transmediale* putting the threat to the sustainability of our planet in perspective with “Perish in Beauty? Climate Change as Cultural Demand”. The interactive installation *Play with Fire* also takes us into forest fires issues, specifically: distribution, detection, effects, causes, consequences, prevention, and forests surveillance.

Digital Artists such as Tiffany Holmes, have since a few years engaged in eco-visualizations projects [3] in order to sensitize audiences towards sustainability issues and climate change. Our approach enhances the eco visualization aspect of such an engagement with the activist component triggered by the gestural interface, which reflects the participants actions directly on the real-time video of the forest.

Interactive experiences engaged with the use of technologies are increasingly embodied in video based environments. Whereas real-time video has been mainly used as a functional tool for surveillance, for informational and safety purposes, the use of this resource has an enormous potential for artistic exploration. Some initial steps in this direction have been made by projects such as *Funky Forest*, an interactive ecosystem where children create trees with their body and divert the water to the trees to keep them alive [4]. *Parque* is also an interactive installation with an ecological message: “the growth of a forest is determined by the amount of attention it receives” [5] – the system recognizes vertical movements as inputs for making trees vector graphics grow. Petros Vrellis’ *Fire* installation [6] poetically displays the compositing of generative fire propagation and destruction effects over static backgrounds and Float4’s FireFX demo shows how performative and responsive generative fire effects can become [7]. *Hand from Above* [8] is an experience that playfully challenges our perception of spaces and objects, enabling virtual and real to coexist in real-time, demonstrating participants’ immediate engagement, and it also evidences how determinant scale is.

The *Games for Change* project hosts an archive with many good examples of the expressive power of the medium for environmental awareness [9]. The work of artists like La Molleindustria [10] that appropriate and subvert videogames as an interactive medium for persuasive purposes has also influenced our work.

In *Play with Fire* the participant is confronted with the information of the burnt forest together with the images of it. Regarding visual effects, we can find virtuous examples of fire effects with cellular patterns in Fedkiw’s computational fluid dynamics [11] and Horvath’s high quality artist-directable GPU implementation [12].

Finally, the inspiration towards acting rather than watching comes from compelling and controversial movies such as Stanley Kubrick’s *Clockwork Orange* (1971), and David Fincher’s *Fight Club* (1999). These works stand out as references to recall regarding the construction of experiences that subvert reality and common sense in order to convey a message.

INTERACTIVE INSTALLATION SETUP

In *Play With Fire*, a surveillance camera will be setup at a selected forest location, transmitting real-time video to the installation space, a room inside of which the performative gestural interaction is contained.

One semi transparent wall is where the mash-up media and information about fire hazards and forests will be displayed. From the outside, the participants are seen as silhouettes of the arsonist – “fire wizards” performing inside the installation room forming a choreography with the changing media displayed. This is also functioning as an attractor for the audience to enter the interaction space. When the participant enters inside the installation room, the system asks him or her to place his/her mobile device on a special deck. Ready to face the screen, the audience member is presented with the start of a fire, triggered by positioning the phone over the deck, and he/she can get ready for the performative interaction.

The participant faces the main screen. A whole body gestural interface based on a depth camera captures the participant’s movement. He/she goes straight into the interaction with the real-time video of the selected forest projected on the whole large scale wall. The sound of crackling fire attracts attention

to the action of the fire and how it is spreading. As the user is prompted to act upon the virtual fire, it will react through real-time generative graphics and fire animation according to the gesture just performed. Intuitive and natural gestures for controlling fire (starting it, growing, concentrating, moving it, extinguishing) have been tested and selected in order to map the user engagement, still allowing further performative explorations.

After a certain amount of time, the fire takes over the trees and forest and develops its own behaviors. If at this point the audience does not intervene by performing gestures trying to extinguish the fire, the forest fire climaxes to a point of no return. Fire flames follow the trees structures. Fire has developed its own behavior and spread through the forest. The scene becomes a spectacle for the audience. Once the fire has climaxed, the amount of virtual damage to the forest will depend on how much the audience has played with the fire, how much it has watched the spectacle of burning trees go on and if he/she had ever tried to stop the flames from taking over. A desolating burnt landscape is the resulting scenario.

The interactive experience ends with the participant being presented with a screen showing information of the resulting damage in the style of a game score: as a measure of the damage generated in the Play with Fire interaction along with a snapshot and general data about how the performance fire damages, regeneration times and possible effects on climate change.

The participant picks up the phone from the deck where he/she had placed it when entering the room and is prompted to open a URL that contains a Play with Fire mobile web application that displays the damaged forest the participant leaves behind and its slow regeneration process. The duration of the forest regeneration and the length of time the application will accompany the participant will in fact depend on the data generated during the performance. Participants will carry it as a memento of their experience for a duration determined by the real-time interaction with the installation.

TECHNICAL CHALLENGES

The implementation of this experience as described above brings some important technical challenges, namely the capture of user gestures, the real-time rendering of fire effects, the illusion of destroying a forest over a real-time video stream, and the mobile component of the experience.

Capturing complex user gestures with fidelity and low latency is a challenging prospect. During the project's pre-production we developed a library of gestures to be discovered by the participants that would trigger specific behaviours of the fire simulation. Although these gestures involve full body movement they can be fully described by arm motion. Taking this into account we are using a Kinect 3D depth sensor and mapping user arm movement to *TUIO* input. This allows us to prototype the installation interaction using common multitouch hardware and software tools.

An impressive and responsive real-time fire simulation is crucial for user immersion into the experience and hard to get right. We are using Horvath's high quality artist-directable fire simulation model developed for film special effects [12] and implementing it in real-time.

Virtually destroying a remote forest presented as a real-time video stream presents some interesting technical challenges. First there's the need to extract approximate tree structures from the video to build a "fuel map" where the fire simulation will take place. This is complex to do in a fully automatic

way, so we'll be using a semi-automatic process where the rough tree structures are drawn over the feed in a calibration step and then the optical flow of image features is used to deform these structures over time.

The next challenge is how to composite the effects of fire destruction over the streaming video. We will have to take some artistic license in the rendering of this destruction. We looked into Melek's work on rendering fire damage [13] and start by blending a black matte over the fuel map to simulate the charring of the wood, and then add smoke, ember and spark effects where appropriate to add some visual impact to the result.

One last challenge that presented itself during development was the uploading of a native mobile app to the user's phone. This approach presented problems related to mobile phone security and having to develop and support a different app version for each phone. The solution we found was to make the mobile application a web application, that would only require that the participant's phone have a web browser in order to check his "score" and the regeneration state of his forest.

CONCLUSION

Play with Fire as an artistic experience has been designed, from the beginning, to be ambiguous, even "wicked". Questions raised by the audience in public presentations have focused mainly on its paradoxical nature: "Won't Play with Fire inspire people to be arsonists instead of forest caretakers?" In his book "Persuasive Games", Ian Bogost introduces the concept of *procedural rhetoric* to discuss how games and interactive simulations can be used to teach a point of view and contribute to effect attitude change [14]. By playing with the system's rules, the users become familiar with it and gain a deeper understanding of its mechanics, allowing them to confront their assumptions and beliefs with this new understanding, through a process of cognitive dissonance conducive to changes in personal attitude [15].

We have designed this interactive experience for persuasive purposes, inviting people to engage in forbidden and dangerous actions in a controlled environment, in order to confront them later with the long term consequences of their own choices. In Play with Fire, participants are initially invited to experience a realistic model of something forbidden, usually outside their scope of possibility. They are allowed to experiment with what is wrong as a learning experience in a game-like environment. This (so called) magic circle [16] – where the consequences are negotiable, played in a protected environment – works not as reality abstraction, but as reality protection.

Collaboratively developed by artists, activists and technologists, Play with Fire is an innovative approach - with a challenging technological component - that comprises a strong dimension on social and natural sciences converging New Media Arts and Sustainability. After the conception, design and initial basic prototyping of Play with Fire, the main implementation of the interactive installation is currently underway and is scheduled to premiere in the Fall of 2011.

ACKNOWLEDGMENTS

This research is done in the framework of the PhD in Digital Media of the UT Austin-Portugal Program funded by FCT (ref. SFRH/BD/42555/2007). We thank CIEBA for supporting conference participation. We also thank AZ Labs for the project development support.

BAPSI SIDHWA AND DEEPA MEHTA: AN ARTISTIC COLLABORATION

Claudia Meoli

In this paper I shall focus on the collaboration between two artists who have created two acclaimed artistic results: the novel *Cracking India* by Bapsi Sidhwa, and *Earth*, its cinematic transposition directed by Deepa Mehta. The collaboration between the writer and the director is interesting not only because they share the same topics, interests and poetic expressions, but also because they are both exiled artists.

Introduction

The division of the Indian subcontinent belongs to the memory of every Indian and every Pakistani, as does the violence of the tragic events that started after the Partition was announced at midnight on the 14th of August 1947. That night the world's biggest mass migration began and in nine months, at least two million people had been killed as a result of ethnic violence. Many women were raped and murdered - it is what Sidhwa and Mehta bring back to human memory.

The two artists are exiled, even if they have not been 'forced' to leave their countries, but, once away from their mother land, they have been able to adopt a new and original perspective on the question of the attachment to one's own origin. My contribution would like to determine how their geo-cultural displacement has made it possible, for them, to deal with the issue of the Partition between India and Pakistan.

Cracking India

In an interview with Derek Attridge (1992:55), Jacques Derrida remarks that:

"A writer cannot not be concerned, interested, anxious about the past, that of literature, history, or philosophy, of culture in general. S/he cannot not take account of it in some way and not consider her - or himself a responsible heir [...] Account cannot not be taken, whether one wishes it or not, of the past".

One cannot not write one's own story, and the story of a community of people: Bapsi Sidhwa was born in Punjab, the Indian region where religion, traditions and history have always played an essential part in the memories and experiences of its inhabitants. Needless to say that Punjab was strongly affected by the Partition; the newly established boundary divided the region with such an impact that since then, people have called the division the 'line of hatred'. Sidhwa was born in Karachi and grew up in Lahore - being a Parsi, she remained a spectator of the Partition. When Lahore was given to Pakistan, she was only a child (perhaps her young perception was particularly shocked by what she was witnessing; it must also be the reason why she adopted a child's point of view in narrating the story of *Cracking India*). What is more, at the age of two, she contracted polio, so she was spending her life in solitude: she did not go to school, and could not play with the other children - it was mainly books that provided her with

a space of freedom. She was an 'outsider' and a lonely person, mainly possessing literature as her company, literature creating for her the alternative world to the cruelty she was facing.

Today, Sidhwa does not live in Pakistan; she moved to Houston, in the United States. Since then, she has often come back to Lahore, where she enjoys playing the role of an observer of Pakistan. Her identity is characterized by a kind of 'hybridity', which is reflected in her books, written by a 'Punjabi-Parsi-Pakistani' writer. In this vein, we can also say that Sidhwa's writing is acutely ironic, and, even more importantly, it is always written in very articulate, though accessible, English –she herself having studied through that medium. Of course, her familiarity with English made it easier for the writer to live in the U.S.A. In *An American Brat* (1993,) she narrates her experience: she has faced her exile in a 'double bind' – that is, enjoying American freedom with a point of nostalgia, in a bittersweet way.

Cracking India is Sidhwa's third book. Published in 1991 under the title of *Ice-Candy-Man*, the novel narrates the Partition of India and its consequences from the point of view of a child. In an interview with Julie Rajan, who asks her why she wrote of events that took place in a distant past, she replies:

"I wanted to write about Partition precisely because so little has been written about. [...] When you see something like that, it becomes a very powerful and important memory" (http://www.monsoonmag.com/interviews/i3inter_sidhwa.html).

Cracking India is not, however, an autobiographical novel (even if there are many precise connections): it is the story of the writer's research into one of the most forgotten and hidden events in international postcolonial history. In order to write a novel devoted to the trauma and suffering provoked by such an incredible historical-social fact, she had to find out information – in her research, what she found out was that people did not want to talk about it; everybody refused to remember the kidnappings and ravages that happened to men and, particularly, to women: "Maybe the hurt was too fresh" the writer says. The question of the women's involvement and their suffering was to become the centerpoint of the novel - in another interview (<http://changingupakistan.wordpress.com/2008/08/29/a-novelists-perspective-on-pakistan-a-conversation-with-bapsi-sidhwa/>), Sidhwa observes that,

"at times of such anarchy, women seem to bear the brunt of the attack – they attack a woman because they are attacking a man's honor. A woman is often used and misused for these purposes".

Being a woman herself, the writer focused on the condition of women in that critical period, by exploring the 'collective repressed' and by giving a voice to its female victims.

Of course, there have been other writers who have written about the Partition, such as Saadat Hasan Manto and Khushwant Singh; but they are male writers, who approach their subject matter mainly from their own perspectives. Sidhwa's feminine point of view proves different: the Partition of India created one of the highest numbers of exiled people, mainly women, in the history of the world. These events are narrated in the novel, even if we never find neat descriptions of what is happening. Precision in historical reconstruction, in fact, does not matter to Sidhwa; what is important is to construct a story where women are at the centre.

The novel tells the story of Lenny, a 7-year-old girl, who suffers from polio. Lenny has a nanny, (*Ayah* in Hindi, and the name given to her character throughout the book), who is a beautiful woman surrounded by people who love her. She has two suitors in particular: Ice-Candy-Man and Masseur, both of Muslim

religion. Ayah is at the centre of a group of friends who spend time together, regardless of the differences in their religious beliefs. Lenny, probably because of her walking difficulties, spends more time with Ayah and her friends, than with the children of her age. Ayah is framed in an interreligious and interethnic circle; when the harmony breaks, it is she who becomes the victim of the Indian-Muslim sectarian war.

Sidhwa uses her character to make her point about the Partition of India, its consequences, and, in particular, its repercussions on women - the events gradually become vivid to the reader, who naturally empathizes with the characters being caught up in the story. It is a story of an 'exile' that begins when people are still in their own homes, when they gradually become exiled in their lands, forced to migrate because of their religious beliefs. We can recall what Julia Kristeva, in *Strangers to ourselves* (1991:8), says,

"In crossing a border (...or two), the foreigner has changed his discomforts into a base of resistance, a citadel of life".

During Partition, borders were first created, and, after the imposition, people had to cross them, leaving their lives behind. The Parsi community played witness to this change - it saw the horror that originated from the transformation, as if it were crossing the border itself - when everything changes, it feels like crossing a border - nothing more, nothing less....

Earth

In his *Reflections on Exile* (1983:185), Edward Said reports some lines of Hugo of St.Victor:

"[...] The man who finds his homeland sweet is still a tender beginner; he to whom every soil is his native one is already strong; but he is perfect to whom the entire world is as a foreign land. The tender soul has fixed his love on one spot in the world; the strong man has extended his love to all places; the perfect one has extinguished his."

The Palestinian scholar further explains,

"that the strong or perfect man achieves independence and detachment by working through attachments, not by rejecting them. Exile is predicated on the existence of, love for, and bond with, one's native place; what is true of all exile is not that home and love of home are lost, but that loss is inherent in the very existence of both."

If this quotation does not sound appropriate for Sidhwa, it seems fitting for Deepa Mehta. A 'hybrid' artist by her own definition, she claims to be a "citizen-filmmaker of the world": not an Indian and not a Canadian either. Actually she was born in Amritsar, in Punjab; as a child, she moved with her family to New Delhi where she graduated in Philosophy. Soon after, she started producing documentaries and she currently lives in Canada. She does, however, travel consistently, from one country to another, continuously trespassing geographical and cultural borders.

In an interview with Richard Phillips (6th August 1999, <http://www.wsws.org/articles/1999/aug1999/meh-a06.shtml>), Mehta says that she has always thought about Partition. She has been fascinated by this event, and also disillusioned by the silence inscribed by Western cinema. When she decided to devote a film to the Partition, her desire was to trespass the fixed images India often recalls to the Western

mind; her aim was to 'de-exoticise' or 'de-orientalize' India - as Said would say. When she came across the novel *Cracking India* by Sidhwa, she thought it was exactly what she was looking for- it was then that the two women artists started collaborating. The chance was there for them because they both felt free due to the distance of time and space. In fact, it was somehow comforting to find someone to share the work with. To make sense of this shared need, and the richness that it created, Julia Kristeva (1991:12) offers her analysis of the advantages of being 'exiled':

"Free of ties with his own people, the foreigner feels 'completely free'. Nevertheless, the consummate name of such a freedom is solitude. [...] No one better than the foreigner knows the passion for solitude. He believes he has chosen it for its enjoyment, or been subjected to it to suffer on account of it, and there he is languishing in a passion for indifference that, although occasionally intoxicating, is irreparably without accomplice. The paradox is that the foreigner wishes to be alone but with partners, and yet none is willing to join him in the torrid space of his uniqueness. [...] Accordance is the foreigner's mirage. More grueling when lacking, it is his only connection – utopic or abortive as it may be."

The collaboration between Sidhwa and Mehta has proved 'utopic': from their intimate and productive accordance, *Earth* was born. According to Sidhwa (http://www.monsoonmag.com/interviews/i3inter_sidhwa.html), Mehta was carried away by the book in such a way that she wrote the script even before signing the contract. That was how Sidhwa wanted it to be: the director had to love her book deeply. At the same time, it was not always easy to collaborate. Sidhwa was always present when the film was being shot; she saw when her title was changed, but, even if at the moment, she did not think it matched the book, she knew Mehta was making her trilogy on the natural elements (*Fire, Earth, Water*). What was really difficult to accept was to see entire sections of the book being deleted: once again, though, Sidhwa understood that cinema is a different media: for instance, it could not contain all the novel's incidents and characters. The most evident and different of the changes relates to the 'end': the novel *Cracking India* follows the aftermaths of the Partition; *Earth* finishes soon after the event, when Ayah is kidnapped. Because of these minute differences, what was becoming clear in their collaboration was that literature and cinema are different; they cannot but rule the experience of reading the novel and of watching the film. For instance, the first part on the screen creates a positive and peaceful atmosphere among the characters in a way that is different from how Sidhwa narrates it in her book; in the second section, everything changes; the tragedy begins; the film changes its register; it becomes darker; it changes its colours... What follows is a short analysis of some of the rich differences between *Cracking India* and *Earth*.

The colours

Colour is an important element in Mehta's films, giving her the possibility to communicate feelings and atmospheres that can be 'felt' by the spectator. It is a powerful possibility and Mehta benefits from it as much as she can, paying attention to the use of colours. Generally, her films have a dominant colour and for this film it was the colour terracotta that came to her mind when she was writing the script. Conversely, she did not want the colour blue. It is exactly like that: the film covers a range of colours from green to yellow, from red to brown; and only in one scene, there appears the bright blue of Ayah's sari.

Michael Taussig, professor of Anthropology at Columbia University, in his "What color is the sacred?" (2006:51), refers to the relationship between Proust and Vermeer, saying that the use of colour in painting is similar to the use of words in writing: "style is to the writer what color is to the painter". Daring a risky comparison, we could say that this dialectics works also for Sidhwa and Mehta: being a director,

Mehta has her own singular ways of expressing sensibility. In her films, photography plays a key role - light is at the core of photography, and one has to know how to use it. Colours change with light, creating various atmospheres and conveying different emotions. These visual elements combine with music - which is always original in Mehta's films. Even though, *Earth* stays faithful to *Cracking India*.

The language

Another difference between *Cracking India* and *Earth* is 'language'. Despite the fact that Sidhwa is Pakistani, the novel is written in English, with a few words in Hindi or Urdu. The official language of India is Hindi; English is common among the upper class and educated Indians. Sidhwa does not draw differences in class, religion, or occupation - every character speaks in English. Of course, this is because of narrative reasons: it would be extremely difficult to read a book with characters often switching language. This limit does not exist in cinema, where a dialogue can be easily understood by adding subtitles. The original language adds realism to the social and cultural picture of the film. English is the *lingua franca* allowing Indians to communicate among the different dialects spoken in India; though it is not the language spoken by everybody. The size of the country and the variety of languages and dialects spoken make it difficult to define India's national language. In this context, English plays an important role - it has lost its negative connotation of being the language of the British oppressor, and it has also developed a unifying function in a fractionated country. If Sidhwa was more or less bound to make a choice, Deepa Mehta decided not to do so. The characters in her film speak different languages: sentences in Urdu, Punjabi, Gujarati and, rarely, in English are pronounced in the film, that switches from one language to another, sometimes mixing Hindi to English: this is a narrative strategy that gives the idea of the 'multilinguism' and 'multiculturalism' of the country.

The British rule

The use of English as *lingua franca* suggests the presence of the century-long British rule, the influence on the politics of the subcontinent and the inheritance it has left. British rule on India is a discussion that is not addressed by the film, while it is clear in the novel, even though neither artist delves deeply into the subject. A scene in the house of Lenny's parents is the occasion to show how this controversial debate can degenerate into a fight. Lenny's parents invite their friends for dinner: Mr. and Mrs. Singh, both Sikh, and Mr. Rogers, an English policeman, with his wife. They are spending an enjoyable night chatting away, when Mr. Singh and Mr. Rogers start arguing; the reason relates to the time when India will be independent, allowing the most crucial points of the debate on British rule to be thrown onto the table. The British imperialistic and racist belief is that the Indians will never be able to self-rule - it is what Mr. Rogers says, strongly opposed by Mr. Singh. They then start discussing what will happen when the British quit India. Mr. Rogers' conjecture is wrong, when he says that the situation is politically confused (the political situation will become clear soon after Partition, with the Congress Party and the Muslim League respectively placed in India and Pakistan); still, he is also right in foreseeing the explosion of violence that will follow. The discussion turns into a fight: as soon as the calm returns to the table, the hosts make a list of the good effects of the British domination in the subcontinent - in the book, conversely, the narration goes on to describe the continuation of a pleasant and relaxed dinner. The point of discussion is presented, the mainstream idea that the British colonialism had, in the end, its advantages: the British built roads, they gave India the regular Post service; they taught the Indians English! Could we expect a better 'comfort' for the death and suffering of so many people involved in the Partition? The novel and the film have played their part in re-opening this question...

CREATIVE SPACES OF THE IMMIGRANTS: REVISITING THE DISCUSSIONS ON CITY-SPACE, TECHNOLOGY AND ARTISTIC PRACTICES

Ceren Mert

Taking into consideration the matters of diaspora and immigrants, and their 'possible' relationship within the translocal creative and technological flows, this paper will concentrate on the films of one of the most recent notable film-makers: Fatih Akin. This paper will focus on whether Akin's films can form an antagonistic creative space in relation to the hegemonic discourse of the practices of the city-spaces where these immigrants dwell.

To start with, as some authors argue I too endorse the view that globalization always remains an unfinished project. The creation of a 'global culture' should not be perceived as a straightforward homogenization practice. Globalization rather encompasses those processes of systemic desegregation in which the local cultures turn out to be thoroughly interdependent and interconnected. [1] After remarking on globalization and underlining the significance of local cultures within the emergence of the so called global culture(s), one could argue that one area of manifestations of this would be cinema, whereas music would be another. Accordingly, the global cultural flows engender new spatializations around various cultural productions of the diasporic peoples, which have an effect on the global (sub)cultures in return. Just as within the sphere of music, cinema too is a medium that has or rather has the potentiality of altering the everyday practices and viewpoints of people as well as reflecting them.

It is within the discussions of space and the process of globalization that we can merge the issue of city-spaces, how they become the focal points of Deleuze and Guattarian conceptualization of deterritorialization and reterritorialization, as Deleuze and Guattari's geo-philosophy environs territorialization and thus flows. Also, the notion of 'desire' is important in their analyses, as it is an underlying factor of flow and the direction of flow. For Deleuze and Guattari, desire enables beings to be pulled towards each other, which produce connections, and it is these connections that are considered in spatial terms by these two authors. [2]

Articulating the geo-philosophical propositions of Deleuze and Guattari in her work as well, one of the interesting conceptualizations about Doreen Massey, I believe, is her elaboration on space. In this regard, she argues that space is initially the product of interrelations—either emerging from a huge, global level or as tiny as one to one relationships. Second, what Massey proposes is that space encompasses distinct trajectories that coexist simultaneously which thus enable the coexistence of heterogeneities. Third, and which is connected to her other two assumptions, is that space is never finished and closed. [3] Hence, space is always a process that is being made which always entails openness and multiplicity. Recalling the process of globalization in the light of these arguments, where mobility and migrations can be seen as flows and becomings at the heart of the process of globalization, or rather glocalization, how can then the so called "migrant" cinema open up new spatializations, thus pave the way for new becomings, or in other words the 'possibility' itself for new becomings? Spatiality that encompasses such possibilities for new happenings and vibrancy, and just for this reason I would prefer to call it a third space. Also, taking into consideration Lefebvre's elaboration on (social) space as a (social) product, [4] Innis

also contemplates on space in terms of technology and its spatial and social organization of knowledge. Likewise, communication technologies simultaneously produce and demolish difference in their subjects. Innis thus depicts technology being part of a more complex apparatus that both brings out and holds back power. Hence, marginal groups resist as well as they depend on the cultural technologies that create their awareness of themselves as margins. [5] Inferring from Innis's ideas on the relationship between space and technology, it could be questioned if and to what extent technological medium is employed by those at the "margins" of society. That is, in terms of this paper, the aggrieved populations utilizing the technological medium artistically, such as that of shooting and producing films, thus reflecting the hardships of their everyday lives and disseminating their voice more "powerfully".

In this respect, Fatih Akin, who is a second-generation Turkish-German director born in Hamburg, became one of Germany's distinct filmmakers in our contemporary era. Or rather, Fatih Akin is a German filmmaker with a Turkish name and Turkish parents. Akin's dislike of the hyphenated identity label can also be observed from his words in an interview after his film *Short Sharp Shock* which gained a wide success in 1998: "If I can't be Fatih Akin, I'd prefer to be known as the German Martin Scorsese." [6]

Consequently, how Fatih Akin engages the city-spaces in his films will also be another crucial aspect that will be elaborated upon. Furthermore, it will be proposed that Akin creates spaces through his films, which can also be thought of as flows of desire that rather form a third space. This third space is constituted through the characters Fatih Akin employs and the cities Hamburg and Istanbul where his films' protagonists are situated or rather unsettled at –just like Akin himself. Such unsettledness can sometimes be seen by their transition between these two cities, or the idea of going back (to their "idealized homeland"), as well as a disturbance or a feeling of displacement they seem to experience in their current city. In terms of city-spaces and the creation of a possible homeland, taking into consideration the engendering of a third space, I will concentrate on these three films of Fatih Akin: his first full length feature film *Short Sharp Shock* (*Kurz und Schmerzlos*) in 1998, his 2000 movie *In July* (*Im Juli*) and maybe his first worldwide known movie *Head-On* (*Gegen die Wand*) in 2004.

In Fatih Akin's *Short Sharp Shock*, the main characters 'Costa', 'Gabriel' and 'Bobby' who are respectively from Greek, Turkish and Serbian family backgrounds are three close friends with "criminal" personas. The viewer also sees a praying father, a representation that, as Rob Burns indicates, "comes perilously close to the figure of the speechless Turk propagated by 'guestworker literature' and the 'cinema of the affected.'" [7] With the 'cinema of affected' Rob Burns addresses the growth and recognition of the diasporic literature in the 1980s, involving the profound effect of the Turkish-German authors, who also influenced the migrant filmmakers. [8] Accordingly, the Gastarbeiter or guest worker experience was worked up in filmmaking. However, starting from the 1990s there emerged a new generation of filmmakers whose works to quote Rob Burns "is above all notable for the sustained attempt to dismantle rather than recycle cultural stereotypes and to open up a 'third space' between the celebration and the denial of otherness." [9] Although these groups of filmmakers emerging in the 1990s are rather heterogeneous in their filmmaking, they still share a common incentive in their desire to break away from the earlier dominant images that portrayed the migrant Turks as victim. Fatih Akin, who is one of the most successful filmmakers depicting this situation, underlined in one of his interviews that he had started to make his own movies because he was reluctant towards those film productions where migrants could only appear as a "problem". Rather he explains that he sees his growing up in two cultures to be an advantage and enunciates as follows: "I do not have to transmit a message of tolerance or deny one of my cultures. I simply link them –in my person and in my films." [10] These words of Fatih Akin can be observed in his films by the way he reflects a peculiar persona in almost all of his film characters. It is as though the ethnic and socio-cultural features remain secondary compared to the characters he deploy;

as if wanting to highlight the uniqueness of each individuality –where people in the so called “real life” may sometimes be blind to, as a result of their apriori prejudices and categorizations.

I also agree with Burns that Fatih Akin is not resisting to position stereotypes in the name of challenging them. [11] Hence, Akin sometimes by fiercely inserting the viewer to the patriarchal dominance and violence where the female protagonists may at times seem to appear as victims, he also manages somehow to subvert and destroy such representations of dichotomies such as victor/victim, oppressor/oppressed and so on. In my re-reading of Akin’s films, such a subversion of the boundaries of such dichotomies are not just in terms of gender or ethnic backgrounds, but also encompass the inner journey of the main characters; as if Akin is shouting out loudly through them to his viewer saying “feel the pain and fear as well as joy and hope in that moment of human existence.” However, in my point of view, such psychological connotations develop as a result of Akin’s exposure of the viewer to the materialistic reality as well as brutality, nevertheless still interestingly managing to resume the hope for the possibility of the impossible, even when the main characters may hit bottom: for example, the way Akin uses spaces of captivity or claustrophobic spaces such as prisons. Again, as Rob Burns emphasizes, “Akin’s films’ prisons are configured directly and either are shown only at the moment of liberation or function as sites of enlightenment.” As towards the end of his film *In July*, the main character Daniel discovers in prison the reason why Isa has been carrying a dead body in his car’s trunk, which allows for a new bond and sympathy between the two men. Whereas in Akin’s film *Head-On*, the prison becomes the space where Sibel visiting Cahit there for the first time confesses that she loves him which in turn changes Cahit’s stance towards life. Accompanying such a transformation in his inner life, when he gets out of jail he has rather a different style and appearance: the reckless and dirty rocker Cahit is gone and a more charismatic and stylish Cahit has come. Hence, the boundaries between the brutal reality and spiritual imaginary all get blurred.

In Akin’s 2004 film *Head-On*, one can remark on his presentation of spatial and temporal transition between Hamburg and Istanbul. [12] Further, Akin utilizes the issue of self-destruction through the male protagonist Cahit who has distanced himself from his Turkish background, therefore cannot speak Turkish well, and who has a suicidal background and loves punk and rock music as well as cocaine. His apartment in Hamburg is as dirty and messy as a pig’s hole. One night in his car, he attempts to commit suicide by stepping on the accelerator and crashes into the wall, later opening up his eyes in a hospital. Just shortly after this incident he meets Sibel, the female protagonist of the film while waiting for his doctor at the rehab center to call him. Just after getting out of the doctors room, Akin sort of surprises his viewers through his character Sibel, who has also tried to kill herself and therefore is too staying in the same rehab center, runs towards Cahit, whom she has never met before, says “you’re Turkish aren’t you? Please marry me.” Cahit in his cool manner rebuffs her in slang and goes away hurriedly. The viewer gets to realize Sibel’s insistence in marriage is only because she wants get free from her family and marrying a Turkish man is her only escape.

Now, going back to the spatial transitions in Fatih Akin’s films, and in this case of *Head-On*, as mentioned earlier, there are two cities: Hamburg and Istanbul. Cahit, after getting out of jail goes to Istanbul to find Sibel, where one immediately becomes aware of the sea, the Bosphorus Bridge and the cosmopolitan city with busy and colorful sideboards at the Beyoğlu area in Istanbul. As in almost all of his films, Akin playfully utilizes space, under various categories in my point of view. In this respect, music is maybe one of the most crucial creators of space in his films. Akin applies music and sounds so eclectically, from punk-rock music, to jazz and soul, to hip-hop, to electronic, to traditional as well as alternative Turkish music and many more. Hence, the ‘lived spaces’ of the characters and the spatial transitions are accompanied by the director’s sophisticated taste for variety of musical genres. For instance, in *Head-On*, the

film opens up with an orchestra of a gypsy band in front of Istanbul's Bosphorus Bridge where a woman sings a traditional love song 'Saniye'm'. This should be seen as the chorus of the movie as it appears a few more times throughout the film. However, as said previously, while Cahit is in the car trying his failed suicide attempt, he listens to Depeche Mode's song 'I feel You'. In various scenes one can hear the song of Nick Cave to the West Berliner experimental group Einstürzende Neubauten.

Another suggestion to why Fatih Akin can be thought of as yielding a third space can be analyzed in terms of Lefebvre's 'representational spaces'. Lived spaces are those spaces that embody the real and the imagined spaces simultaneously. Or to put it in Lefebvre's words, "representational space is alive: it speaks... It embraces the loci of passion, of action and of lived situations, and thus immediately implies time... It may be directional, situational or relational, because it is essentially qualitative, fluid and dynamic." [13] Within Lefebvrian trialectics, the third space, that is, the representational spaces also embody the first and second spaces, which are the perceived and the conceived. Likewise, Fatih Akin's films can be seen as this gateway to the third space because of its expressiveness of the diasporic community. Such an expressiveness is not only seen in the case regarding the Turkish diaspora, but also the Italian, just in the case of his 2002 film *Solino* or the Greek in the case of his 2009 movie *Soul Kitchen* and so on.

In terms of Akin's expressiveness of the lived spaces of both those in Hamburg and in Istanbul, I prefer to call it a possible representation. One of the reasons for this is my own problem with the issue of 'representation' as when one declares that s(he) represents something or a group of people it would never be a one to one replica of what is being represented. Second, representation could itself entail a hegemony resulting from relations of power. Also, as there is a constant flow and dynamism within the spatial praxis, there will remain possible gaps as well as a possibility of change. Nevertheless, with its 'possible representations', successful cultural productions such as the films of Fatih Akin, I believe, have the power of altering boundaries of a globalizing, glocalizing or translocalizing world and its everydayness. Hence, recalling Deleuze and Guattari, by such an expressiveness through his films Akin de-territorializes the boundaries of the social space and its cultural flows and desire, in order to incorporate his own desires and thus re-territorializes them.

Akin's characters are not trapped within a victimized space, but they interact within the everyday life with others of various backgrounds. Respectively, Akin's films indicate a move from the cinema of the victimized, or the affected, or the subaltern to a cinema of hybridity. Although, the viewer is presented with characters that are attributed local aspects of various ethnic backgrounds, they interact and engender alliances or disaffiliations with each other within a transnational spatiality and temporality. For instance, one of the main underlying preoccupations of the director in his film *In July* seems to be the idea of "boarders". I view this film as standing for Akin's own transnational imaging of the world and his preoccupation with questions such as passports, borders and the reasons of restrictions for crossing territories. As in most of his films, Fatih Akin reflects the utopia where he crosses borders in order to achieve a better place that is symbolized with the city of Istanbul. Correspondingly, the male protagonist Daniel who is a shy schoolteacher with a routine life in Hamburg, one day buys a ring with a Mayan sun symbol from a street vendor called Juli (July). Juli tells Daniel that he will find his true love by the guide of this ring and that he will recognize that person, as she will too have the same Mayan symbol of the sun. However, Juli, who herself fancies Daniel believes that in the end he will understand this person is Juli herself. Later on, Daniel falls in love with a mysterious Turkish woman named Melek ('Angel' in Turkish), from Berlin, who comes to his town wearing a t-shirt with a sun pattern on, leaves for Istanbul for vacation a day after. Daniel being so charmed by Melek believes she is the one hence decides to catch up with her in Istanbul. It is after this incident that the road trip begins in Hamburg, passes through Bavaria, Hungary, Romania, Bulgaria and then it finally ends in Istanbul. In the beginning of his road trip while in

the car, Daniel coincidentally sees Juli who is hitchhiking. The paths of Juli and Daniel will intersect from time to time where in the end of the film, Daniel will realize that his so called “sun” that he was searching for and going after was not Melek but Juli herself.

Deleuze and Guattari’s concepts of smooth space, deterritorialization and nomad can be very well applied to *In July*, as well as to his other films. However, in this case of *In July*, the deterritorialization takes place as part of the road trip of Daniel and Juli where Akin seems to be teasing with the ideas of physical borders and the official documents needed to prove that one belongs to a specific place. This film, according to me, is most probably one of the director’s best manifestations of his emphasized transnationalism and hence his so-called nomadic characteristic that is expressed through his creation of smooth spaces. The smooth space, for Deleuze and Guattari, is the space of the intensive becomings and the nomad, whereas the striated space is the product of stratification, especially that is caused by the State apparatus. [14]

I believe as being part of the second-generation youth with a Turkish descent, Fatih Akin would not be the migrant like his parents, but a nomad in Deleuze and Guattarian terms. As he moves while he is seated, just like the nomad; he is from Hamburg. What he is right now, that is, his worldview was formed through his experiences in that city, hence Akin’s hometown. However, the director himself moves globally as part of what he produces cinematically. In this respect, it would not be wrong to argue that he creates smooth spaces through his expressiveness; in other words through his cultural productions of films, where one could witness his criticisms as well as his hope for a better world. One of the manifestations of this would be the multilingualism in his films: Turkish, German, Greek etc would appear in different parts of his film as well as the variety of sounds and music he employs as mentioned before. Rather than the nations, we see that it is the cities that have a profound emphasis in the films of such second and third generation of filmmakers, which would not be a surprise when taking into consideration the emergence of a new global cultural economy built around city or urban spaces. To recall Lefebvre once again, space is socially produced. For this reason, it could be thought that humans create the spaces where they live and therefore it could be remarked that space embodies the ‘political’ as it involves the appropriation and distribution of resources within the everyday life. However, the openness and the multiplicity attributes of space, as Massey have underlined, also engenders the possibilities and changes yet to take place. In this respect, it could be thought that Fatih Akin is one of those artists who reshape the dynamics of spatial formations through his questioning and expression of the everyday lived spaces of the ‘displaced’ peoples and their so called “differences” for a cultural reconsideration of spatial politics.

HYPERIMAGE RELOADED. THE EXPANSION OF THE PHOTOGRAPHIC IMAGE IN VIRTUAL SPACES

Karin Mihatsch, Roswitha Schuller & Markus Hanakam

“HYPERIMAGE reloaded. The expansion of the photographic image in virtual spaces” is based on the ongoing interdisciplinary collaboration between the artistic practice (Hanakam & Schuller; artists, Vienna/Austria) and the art/cultural sciences (Karin Mihatsch; researcher, Paris/France).

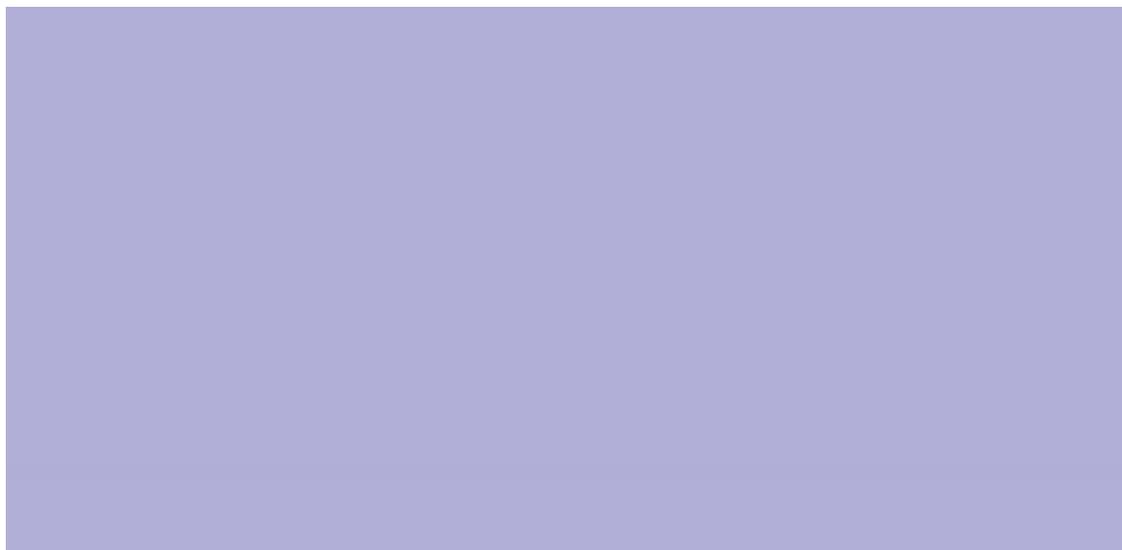

Fig. 1. Palaces & Courts, 2009/10, Markus Hanakam & Roswitha Schuller, web-based Computer Application (Flash); Screenshot Detail, copyright Markus Hanakam & Roswitha Schuller.

Fig. 2. Palaces & Courts, 2009/10, Markus Hanakam & Roswitha Schuller, web-based Computer Application (Flash); Screenshot Detail, copyright Markus Hanakam & Roswitha Schuller

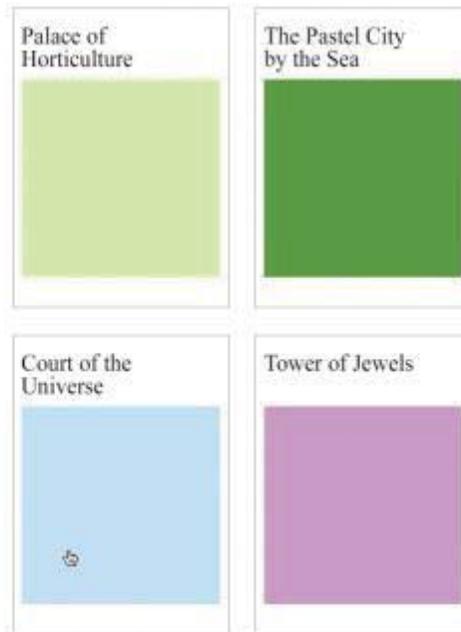

Fig. 3. Palaces & Courts, 2009/10, Markus Hanakam & Roswitha Schuller, web-based Computer Application (Flash); Screenshot Detail, copyright Markus Hanakam & Roswitha Schuller

This paper is based on the ongoing interdisciplinary collaboration between artistic practice and the art/cultural sciences. It is intended to broaden and deepen some of the issues raised during the interworking of the online-work “Palaces & Courts” (1) by Hanakam & Schuller. The work – based on the imagery of photography – was created within the ongoing discourse with the researcher Mihatsch. (2)

From his concept of the World Wide Web, Tim Berners Lee paved the way for a wide distribution of images on the Internet. These images follow other regulations than printed images and are committed to the process: links between images may be set by respecting a network or structure called “Hyperimage”. According to this structure, any image can be integrated in any network or sequence. These sequences may be narrative or not, transparent or not.

The Matrix behind “Palaces & Courts” (“P&C”).

“P&C” is a Flash based computer application for online use basically working on various Pools of Text/Image information in connection with random generators. These so called “Pools”, which are extracted text fragments from the exhibition catalogue “Palaces & Courts of the Exhibition” by author Juliet James, attempt to give an overview of the Panama Pacific Exposition San Francisco from 1915, in

terms of describing the exhibition area, its palaces, courts and intersections as well as the exhibit, showcased in this temporary World Fair architecture. The catalogue text can now be found online as a digitalised version at Project Gutenberg.

The artwork “P&C” works in two dimensions; reconstructing the architectural setting in an abstracted and interactive mode as well as distilling the atmosphere of a World Fair of a time, that nowadays appears to be nostalgic. The basic graphic pattern consists of uni-coloured fields in combination with short texts; these may appear in a group of four, or as single units or as just “detail”, which takes the single colour tone only. In a group of four, every colour field has the same quotient of grey, so there is always the impression of a harmonious colour play.

The Matrix of “P&C” is simple in its programming, but confusing to the user, as it does not follow a tree-like structure, as one could expect on the first clicks. There are four instances -which form pools- the random generator can revert to: Architecture (A), Exhibit (E), Exhibit Detail (ED) and Colour (C).

Pool A is composed of architectural terms of the world fair; for example “Palace of Varied Industries” or: “Court of the Ages”. Pool E refers to single exhibits inside these Palaces or the various Courts. Both A and E pages always show a group of four. ED is a direct link from one element of E. Finally C shows details from EDs.

The starting page always shows the user A, which can link to the pools A again and E; this action continues randomly.

Once the user gets onto the instance E, then E or ED is linked in; this action also continues randomly. Once the user gets onto the instance ED, there is only the option of linking onto C, and in this case it does not link to the whole pool of Cs, but only onto the colour that is connected to the colour from the previous exhibit detail page. Once the user gets onto the instance C, this may randomly link back to the previous ED; or to pool A, or to pool E, or to pool C.

Behind this Matrix, that is not over-complex, lays the artists attempt to mirror strategies of pictorial production as well as the motional and atmospheric embedding of this production within Web2.0. This paper is also intended as an interplay between a theoretical discourse about re-production of (photographic) images, the structuring of images and a media-artistic approach towards this issue.

Creating the Hyperimage.

The development of the Internet dates from the 1960s and was a coproduction between scientists (content) and the US military (budget). (Warnke, 17f) At the beginning economic reasons were not the focus, but rather the exchange of information in a scientific context. The first networks were developed in the USA (Paul Baran: ARPANET with following applications from the early 1970s: TELNET, FTP and E-MAIL) (Warnke, 34ff) as well as in Europe (Donald Davis: MARK I, opened in 1969). (Warnke, 20ff)

Beside these there were several other networks. To enable communication (links) between the different nets, the Transmission Control Protocol (TCP, presented in 1973) was introduced. TCP and the Internet Protocol (IP) permitted the connection between different networks. (Warnke, 43)

In the late 1970s/early 1980s the first PCs, Apples and Macintoshes came on the market. For this reason and due to the dissociation of the Internet and the Military, the user-community enlarged remarkably despite geographical limits. From 1989 to 1992 the WWW was developed at CERN at the suggestion of Berners Lee. (Warnke, 46ff) There, different research teams worked on „non-sequential writing". The so called "Hypertextsystem" offers a references-net: Consequently, researchers can work simultaneously but in an independent way on the same document. (Warnke, 50ff) This innovation lays the foundation for the distribution of images on the Internet. The processual images on the net can be integrated in the Hyperimage-Structure that allows a non-sequential link-network and creates a sort of narrative structure between images.

Besides the structure of Hypertext and Hyperlinking; what is especially intended by using the term "Hyperimage" is not only its quality in web-based structure based on its programmatic level, but its very distinct quality of unfolding narration, plus an atmospheric "sense" of the topic it is related to, which can be allegorised by the term "cloud". Continuing with the example of the world fair catalogue – how can a physical representation of the world be transferred into the virtual? And in the sense of this transforming process, taking a world fair catalogue and reconstructing it as an online computer application is so much an allegory for the internet itself. It is about putting a physical setting into an imaginary setting; digitalisation and virtual re-construction then have narrative quality, in the sense that the virtual space unfolds an imaginary space as we know it from literature or gaming. This shift from "analogue" imaginary to "digital" imaginary spaces – the difference cannot be made by the term virtual itself - may be caused by a crisis of physical space, a process that Paul Virilio describes as "the aesthetics of disappearance". (Virilio, Schroer 263)

From exhibition structures and guiding systems to image structuring in networks.

Paul Baran defined three different communication-net-systems: the star (centralised), the tree (decentralised) and the interconnected net (distributed). All three net-structures do not correspond to the Internet. The Internet is rather provided with a lot of nodes linked with little links and little nodes linked with a lot of links. This is typical for a scale-free network. The research-group around Albert-László Barabási tried to display the "continents" of the WWW. This attempt showed the wish to reproduce visually a given situation. (Warnke, 106ff) The desire to visualise the world became apparent in the universal exhibition a long time ago. For example, the "Panama-Pacific Exposition of San Francisco" presented a representation through the latest inventions and fabrications. By the decontextualisation of the traditional frame and this new structuring of the exhibit objects, another perception is evoked amongst the beholders. (McLuhan). So, our world is translated into another structure by original objects and representations.

The representation-process is submitted to another translation by the catalogue. (3) On the occasion of the "Panama-Pacific Exposition" the catalogue „Sculpture of the Exposition Palaces and Courts" was published. It contains texts and BW images and documents on the architecture and sculpture of the exhibition. So we can say, that in a linguistic and visual way, the catalogue focuses on the structure providing elements, like the pavilions (= nodes), independently from the exhibited content. (The IP also doesn't care about the content.) So the succession of the chapters proposed by author Juliet James could be considered as the representation of a way (=links) through the real exhibition/network of pavilions.

The catalogue is organised in a tree-like-structure. It is introduced by a general foreword, which aims to give a certain orientation to the reader. The reader then has the option to follow the sequence proposed by the author, or to follow their own personal order.

There are different online versions of this printed catalogue. Here we will have a look at the OPEN Library version.(4)

The formal characteristics such as pages and chapters, have been maintained in the (animated) scans of the catalogue.

The typical internet structure is not visible for the user at first glance, but influences the handling and the reception (Genette): instead of thumbing through the catalogue, the user clicks on the pages, the haptic sensation with the object "book" gives way to visual interaction with the screen. Finally, the dimensions of the pages have been adapted to the screen format. (Malraux) Another difference between the printed and the online version is the choice of having the catalogue read to the user. This processual characteristic is an element that cannot be translated into another media.

The structure of the real exhibition is very well presented in the online version: the internet technique permits the showing of several small pictures of the catalogue pages at the same time. This application renders possible a new point of view of the exhibition structure.

As users we grew up with the "traditional" internet of the 1990s, that was organised mostly in tree-like structures, a setting that represented reality in a form with reduced complexity without limiting the possibility of listing content. With the rise of so called Web2.0 applications, our orientation through the internet has changed. The term of "surfing" may still be appropriate to the single user, although this new 'wave' carries along with it, much more individual information than ever before. Users show a tendency to develop a second "reality" inside the "virtual reality" (an example is "Second Life"), so there is a huge contingent of highly individual data transported via the internet. To come back to the media art context of this paper, the example of "P&C" shows an attempt to make this process of stumbling through pictures and stories, without finding the way back or knowing how one got there, visible.

Narrative aspects, associations and the role of the beholder in hierarchical and net-like structures.

The narrative is accented by the dramaturgy developed by Hanakam & Schuller. "Dramaturgy" is described - in the German Duden - as the "teaching of the outside structural form and the regularities of the inner structure of the drama [...]" This definition evokes the presentation structure which is put on centre stage: the frame will be visible.

The issue of the narrative within the internet is spreading in various directions, as it deals with hierarchies, power, communication, psychological aspects and many more themes. With "P&C" the focus is set on the main aspects of reproducing physical space and developing a kind of stage-like setting; principles known from literature as well as from gaming. Indeed, the matrix of "P&C", and the immersive aspect on the user, is quite similar to Role Game Playing, a play-structure at the intersection between story-telling and gaming, that is also strongly connected to improvisational theatre, but without a clearly defined audience.

Three-dimensional elements disappear in photographic (digital) reproduction. The picture is reduced to two dimensions. Hanakam & Schuller break up this two-dimensionality thanks to the narrative moment: the beholder takes an active position (Push and Pull Media) and follows a way/parcours through the structure. The beholder/user moves through the space of the universal exhibition using imagination on the one hand, and on the other hand by paging through the catalogue "Sculpture of the Exposition Palaces and Courts". This all doesn't happen in a linear way, but follows the non-sequential linking system.

"P&C" makes the transformation of the physical world into the imaginary playground visible, as it unfolds this transformation process visually, in re-assembling text passages and by offering a colour-based guiding system that gives the most possible latitude for association.

Photography in the light of the transformation of its materiality in depictions of exhibitions, printed and online exhibition catalogues.

There are no longer any images in the computer system, only binary codes, which can represent either image, text or sound. So the image itself disappears by being translated into another coding-system. It only evokes the impression of still being a picture. Image and text are now at the same code-level; only the user makes a perceptual difference.

The uni-coloured picture on the screen still has the same density of data information, as the "concrete" picture would have; though the information to its beholder is at first sight less complex – in consequence the "abstract" picture will be assumed as complex to, depending on the effort the reader has to put into its interpretation (McLuhan).

In contrast to analog photography, which serves as a memory tool, digital photography devotes itself to visual communication, according to Andreas Schelske. (5) This means that the digital image communicates in an active way, whereas the analog picture rather memorises in a passive way (Push and Pull media). So, we can speak about an interactive situation between digital data and the beholder.

Setting up a digital representation of a genuine physical figure always results in a third, different figure, not only within the internet, but in digital media in general ("The virtual reality"). So this „third“ should not be analysed in reference to its representative quality, but also by its transformatory effects – that impact on structure, narration and aesthetics.

AUGMENT_ME: AN ALGORITHMIC MEMORY, ABSENCE AND PRESENCE IN THE CLOUD

Brad Miller

Can you have a memory without photographing it? Where does a memory live? How do we make sense of them? If it's online, who owns it? What is association at a global scale? What are the conventions of western time and how might that be visualised or utilised? Can you live forever in the cloud? This paper examines these questions through the media art installation *augment_me*.

augment_me, 2009, Brad Miller, Installation, Artspace Sydney. Image Copyright Brad Miller.

The ultimate promise is that the flow of data may restore the flow of life when it is temporarily halted. Biological death becomes a small death, data becomes the through line that joins old subject to new. [1]

Data and Identity

The autobiographical starting point to *augment_me* was an ontological crisis not dissimilar to the one experienced by the protagonist in the Italo Calvino story *The Adventure of a Photographer* [2] that Lizzie Muller cites in her article [3] about my interactive media installation *augment_me*. When what was to become *augment_me* began, I was an amateur photographer resembling a life logger who lackadaisically aimed to record every moment of his life.

In 2000, prior to the existence of Facebook® and Flickr®, I bought a low-resolution digital camera on a trip to China. The speed, ease and in-expensive production costs the camera afforded me meant that I was soon obsessively snapping everything: the daily state of my bed, an empty car park, signage, friends at a wake, a flower, architectural detail, a sleeping girlfriend. Eight years later, I bought a digital SLR camera with better lenses and more capability. The photographs changed. There were panoramic landscapes, a closer attention to skies, a greater awareness about light, angle, resolution and focus – they sat alongside the ‘snaps’ with no superior value ascribed. My only interest was the actual moment and recording it. Those 12,000 or more photographic moments, taken over 11 years, became the images comprising the *augment_me* database: my through line that connects past and present, the banal and significant, public and private, life and art.

Also germane to my obsessive recording and the subsequent creation of a database was a loss of artistic identity, in part a result of the fact that the technologies (for example, the CD ROM including the Mac “Classic Operating system” and analogue video) that I had worked with early in my artistic practice had become redundant and were superseded by other technologies. Consequently, my work [4] and the evidence of its existence disappeared. The loss was traumatic. *augment_me* was born, I came to understand, only retrospectively, from an anxiety about not disappearing as a creator.

In early 2008, I mocked up the first version of *augment_me* on a computer with multiple screens; in November 2009, the first public version was exhibited at Artspace in Sydney, Australia as a large scale installation, using continuous, long format projection, a responsive granular synthesis soundscape[5] using multi-channel audio and video tracking (the interface between the media and the audience is through this tracking system).

Mediated Memories

Films or photos are not “memory”; they are mediated building blocks that we mold in the process of remembering. [6]

Definitions of memory and experience are inextricably linked up with notions of place and time, notions that obviously affect our memories. As memories are increasingly mediated and thus constructed by networked technologies, the boundaries between present and past are no longer a given. [7]

A memory can be of a moment, an event, a feeling, a person, or object – existing in the past, remembered but not always reliably. Memories can be repressed, re-configured, forgotten and re-found. If, like the photographer of the Calvino story, I set out to photograph every minute of every day, I would fail to capture my internal life and the internal lives of others. How to photograph aversion? Contradiction? A lie? Can I have a memory without photographing it? Yes, of course.

My focus on memory, is not memory as the subject of philosophy, cognitive psychology or neuroscience but is specifically, about the interplay between memory and technology transforming how we create identity and memories – and possibly miss, in that process, the elusiveness of identity and memory.

I have described *augment_me*, in the past, as a memory machine of sorts. It tracks my relationships with people, things, places and scenarios via the use of streaming photographs and an algorithm, devised by

me and a software programmer, [8] which is used to structure the flow of thousands of photographs unfurling in horizontal film-like strips, sometimes in different directions, triggered by the movement of a viewer, under sensors, in the exhibition space.

The horizontal, moving film-like strips, other than the nostalgic allusion to super 8 or 35mm, were devised originally because I wanted to make use of western conventions of time used in Mathematics and Science: negative space or time (past) is to the left and positive space (future) is to the right; at the center is the origin (stasis). And so, with *augment_me* the viewer can change the film strips' velocity and direction, by moving their position relative to the center line of the installation. With a movement, the viewer can make the strips appear, at least conceptually, to move back in time or forward to the future.

Walking into the dark space of the gallery, the viewer was not always aware that their movements in the room were triggering the shift in speed and change in the direction of the horizontal strips. What I had not predicted was the oft-repeated impulse of the viewer to move closer to the individual photograph, the want to take a closer look, to stop the flow of data so they could connect with an image.

This presented an opportunity to re-think not only the interactive element of *augment_me* but also how I thought about memory. To take a photograph or be in possession of one, to feel that you have somehow entrapped the experience by making it still in time is a denial of the slippery nature of time.

When I began, I didn't question the "truth" of the photos, they were a record of my experiences, places and people, light and darkness. As the database grew and I was able to manipulate and alter the flow and order of the images, I was able to re-make the memories, alter the context of each individual photograph within the greater whole and to each other. My relationship to the images became more plastic, less resolute and so did the "truth" of them. I relaxed. Perhaps because I no longer feared the memory disappearing, stored as it is in cyberspace, in the cloud.

I came to see the photos less as mementos significant only to me and more as fragments caught in a digital stasis which when re-arranged could throw up new meanings and associations – not only for me but for others and how they think about their own mediation of memories.

augment_me, as a form of algorithmic memory provides an opportunity to experiment with the record of past observations and images evoking memories; I re-make them and their relationship with one another, I disprove, for me, their fixed place in the hierarchy of my memory.

The modularity and flexibility of media creates the possibility of an algorithmic memory: an increasingly intelligent self-organising extensible memory which can circulate independently of human intervention. [9]

ETHERNET ORCHESTRA: INTERDISCIPLINARY CROSS-CULTURAL INTERACTION IN NETWORKED IMPROVISATORY PERFORMANCE

Roger Mills

The study of interdisciplinary cross-cultural interaction in networked audiovisual performance serves as the starting point for Ethernet Orchestra's 2010 telematic music improvisation and live cinema performance, *Distant Presences*. This paper outlines and technical facilitation of the performance, evaluation methodologies and the creative strategies employed by the dispersed musicians and visual artists to collaborate remotely.

Screenshot of networked live cinema mixing by Neil Jenkins, Graziano Milano and Helen Varley Jamieson in VisitorsStudio interface. Used with permission of the artists.

Introduction

Technical and creative strategies involved in collocated audiovisual performance have to be reconsidered when performers are separated by large geographic, cultural and “acoustical distances.” [1] While a burgeoning knowledge of eclectic network performance has illuminated many of the inherent technical issues involved with dispersed interaction, there remains poignant issues of intercultural perception and cognition in interdisciplinary, networked collaboration. This paper seeks to address these concerns by examining the strategies that the remote musicians and visual artists utilized in realizing this improvisatory, telematic audiovisual performance. Considering differences in perception across the dispersed collective, it adopts a semiotic perspective focusing on the role of metaphor in understanding signs in improvisatory musical and visual interaction. Viewed through the framework of distributed cognition, the interface and use of video is examined as features of a “conceptual field” [2] for evaluating collabo-

ration across artistic disciplines and cultures. The collaboration combined intercultural musical improvisation and online image mixing spanning four continents and time zones. Networked musicians were located at the University of Technology, Sydney (AU), Kunstmühle gallery, (DE), and Londrina (BR) with visual artists in Sydney, London and Munich. The performance was broadcast by FBi Radio, Sydney, and streamed on the Internet as “Radio You Can Watch”, allowing listeners to view the accompanying live visual mixing to the radio broadcast. This form of cross-cultural, interdisciplinary collaboration affords unique opportunities to investigate the technological and creative strategies involved in producing a live, networked audiovisual performance for radio, which as far as it is known, unique for the medium.

Ethernet Orchestra is an international network music ensemble comprised of skilled musicians from a diverse range of cultures and improvisatory traditions. The instrumental make up of the group includes, Turkish oud & bendir, Mongolian horse fiddle, throat singing as well as guitar, trumpet (played the author) and Max/MSP electronic processing. The collaborating visual artists are also known for their work in a range of audiovisual practices, however in this performance they would be best described as live cinema artists rather than VJ’s. The term VJ initially described video jockeys presenting videos on MTV (Music Television), but as Makela (2008) argues “metamorphosed to include video performance artists who create live visuals for all kinds of music.” [3] However, the term also carries associations with club culture in which the VJ’s contribution is to mix visual projections to accompany a DJ’s music set. While these distinctions are somewhat diffuse, live cinema or real-time audiovisual performance is seen as routed in narrative art practices, with a history dating back to lantern shows and shadow plays. Network artist, theorist and participant in this performance Helen Varley Jamieson notes how problematic these terminologies can be, but adds that a more succinct term CJ (Cyber Jockey) has emerged recently to describe Internet based audiovisual performance.

Networked Audiovisual Connectivity

Connecting musicians and visual artists across four time zones with low latency and high audiovisual fidelity required a combination of network interfaces capable of synchronizing dispersed collaboration without interruption. While documented networked audiovisual performances have employed bespoke interfaces on high-speed research networks, Internet2, KAREN, CERNET2, the multifarious configuration of regional networks, participant addresses and the machines being used in this performance required accessibility rather than speciality. This was particularly necessary for the performers participating from remote locations with domestic connection speeds. Player communication between the audiovisual interfaces was also paramount for synchronization and the demands of a live a radio broadcasting schedule. This was achieved by a combination of IRC (Internet Relay Chat) and interface text windows coordinated at the central hub studio at the University of Technology, Sydney. Although a radio broadcast was the principal performance medium, the station studios were not technically equipped to facilitate the performance. It was therefore decided that the University of Technology, Sydney would best provide the technical hardware, sound requirements and network to run two bandwidth hungry interfaces needing fast up and download speeds.

While a number of network audio interfaces could have been employed, it was decided to use the ‘plug-n-play’ platform eJamming, a proprietary multi-user interface, using peer-to-peer architecture that transmits 44.1 kHz 16 bit (CD quality) WAV files. The interface sends packets (signal as digital information including its destination) via UDP (User Datagram Protocol), making it a fast, high fidelity platform for synchronous connectivity. Its low level latency is achieved through compression algorithms that

shrink the file size for high packet flow, and its peer-to-peer configuration allow it to route the signal directly to players rather than via external servers. This transforms large network latencies of up to 150ms down to approximately 11ms (imperceptible) in the interface, effectively creating collocated acoustics for the networked players. Player soundcards are connected via USB, and audio in-and-out parameters control monitoring levels. A text window provides communication between musicians facilitating synchronous dialogue between performers.

The "live cinema" mixing was performed in the multi-user audiovisual interface VisitorsStudio, a Flash based environment, enabling artists to "upload sound files and still/moving images (jpg, png, mp3, flv, swf) to a shared database, mixing and responding to each other's compositions in real-time." [4] Performers upload images, short animations or movie clips, which are then selected and looped in a mix window. Images and clips can be synchronously manipulated, changing parameters such as size, perspective, contrast and filters. Artists improvise with collages of static and moving images responding to each other and the audio stream in real-time. Figure 1 shows a screenshot of the networked live cinema mixing in the VisitorsStudio interface.

As the hub studio was located some miles away from the radio station, the networked performance was streamed from eJamming to the station studio via the Internet broadcasting platform Nicecast. Nicecast is a client-server platform that broadcasts audio as a compressed Internet stream to other machines via a URL (Universal Resource Locator) or web address. This allowed the station to then re-broadcast the stream on their terrestrial frequency 94.5 fm, along side the stations own Internet stream. Both local and international listeners were then able to watch the live cinema mixing via the url <http://www.visitorsstudio.org>. For artistic and evaluation purposes the visual mix was recorded and archived through the interfaces sequenced file playback system, and sound and video of the musician's performances was also recorded. The complete audiovisual performance can be viewed at <http://www.eartrumpet.org/distantpresences>. Despite the array of dedicated network interfaces, the humble telephone served the purpose of tele-communication device between the station studio and the university in a pre-performance interview with the author.

Collaborative Networked Performance

As an area of research, collaborative, networked performance has become a point of considerable interest in recent years. As far back as the 1970s LAN (local area network) computer music experiments of the League of Automatic Composers to contemporary WAN (wide area network) performances of the Stanford SoundWire group, Pauline Oliveros, Avatar Body Collision and Furtherfield, musicians, artists and researchers have been developing technical and theoretical frameworks to enhance and evaluate interdisciplinary, dispersed networked performance. While the examples provide a small contingent of practitioners worthy of inclusion in any networked performance review, they represent a cross section of contemporary interdisciplinary approaches to it. This includes diverse practices such as network acoustics and technology research, composition, improvisation, theatre and social activism.

Gesture and Dispersed Perception

Within the ocean wide area network linking Sydney, Londrina, Braunschweig, London and Munich, three of the musicians were collocated in the hub studio at the University of Technology, Sydney. All participants recorded their individual performances on video providing useful data to contrast the gestures of the collocate group to that of the remote musicians who were unable to see each other. It should be

noted that participant observation and analysis of gesture in this paper is applied only to the networked musicians. Evaluation of the video recordings revealed that where musicians could see each other, they rarely used the opportunity to coordinate their ensemble collaboration. This is in line with previous research where the video relay of networked performers primarily assumes “the purpose of providing an experience for the audience,” [1] and that dispersed musicians usually don’t visually monitor their collaborators during a performance. The role of gesture in improvisation and musical performance is well documented, and has often been seen as a principal problematic for musicians collaborating in the non-visual networked environment. However, in the context of the networked improvisatory performance, the use of a live video stream does provide participants with what Hutchins (2005) describes as a “material anchor” in their “interaction of mental...and material structure.” [2] Viewed through the lens of distributed cognition, material anchors are also present in the appearance of collaborators names or cursors in the interface.

Multimodal Improvisation

The primary focus of the *Distant Presences* performance was not only intercultural and interdisciplinary improvisation but to explore this as a multimodal radiophonic performance. Theoretical musings on the interplay of sound and image in audiovisual arts and experimental film are historical in their weight and depth, however recent discourses have centered on “concepts of interactivity” [5] and montage, veering away from the model of a linear celluloid medium. Live cinema mixing with music and sound art has also caught the attention of technologists keen to create novel interactive interfaces, and artists wanting to re-imagine or “redefine what cinema can be.” [6] While the collaborative domains of live cinema and music are born out of collocated gallery spaces and club culture, it is the spontaneous entwining of the two that informs its methodologies. Makela (2007) argues “what differentiates live cinema from normal cinema is the ability to improvise the narrative or concepts, to alter their course as the performance progresses.” [3] In networked audiovisual performance it is this same “interplay of the audiovisual, performed and improvised in the momentary negotiations of the participants” [6] that shape this experience.

Significant in *Distant Presences*, is how these negotiations are shaped and mediated across disciplines and between cultures. Analysis of post performance interviews and audiovisual instances reveal similarities in approaches between musicians and visual artists collaborating in cross-cultural interdisciplinary improvisation. While there are obvious differences in the creation of content, i.e. pre-performance selection of images versus spontaneous creation of music and sound, what emerges is the use of metaphor as a signifier for perception across the audiovisual spectrum. As Chion (1994) suggests, “listening with the ear is inseparable from that of listening with the mind, just as looking is with seeing.” [7] From a semiotic perspective, the research identifies what Lakoff and Johnson (1980) refer to as “ontological” and “orientational” metaphors as potential experiential signifiers in dispersed interaction. They argue that ontological metaphors give us a way to refer to experience as “ways of viewing events, activities, emotions, ideas, ect., as entities and substances”, which allow us to “refer to it, quantify it, identify a particular aspect of it [...] and act in respect to it. [8] Analogous to their given examples, rhythm, timbre and melody can be considered entities in demonstrating a musician’s experience of tele-musical improvisation. The examples illustrate ways in which dispersed collaborators can think about, and refer to such experience.

That *rhythm* is *pushing* the music to a *climax* at that point.

The *timbre* of that sound was so *cold* that it made the *melody* really *stand out*.

Orientation metaphors, relate us to our “spatial orientation: up-down, in-out, front-back, on-off, deep-shallow, central-peripheral”, however they do not “structure one concept in terms of another but instead organize a whole system of concepts with respect to one another.” [8] This gives a spatial orientation to concepts, for example “happy is up; sad is down.” [10] Applied to networked, multi-modal improvisation, such associations are significant in communicating emotion and meaning across cultures and disciplines. Examples of this emerge from the analysis of post performance interviews where musicians and visual artists reflect on their awareness of metaphor during the performance. This often occurs during complex, cognitively demanding situations in what Schön (1995) describes as reflective practice in action. Musicians and visual artists appear to process their perception and creative expression, while producing spontaneous audiovisual dialogues, revealing “a capacity for reflection on their intuitive knowing in the midst of action [...] and further to “use this capacity to cope with the unique, uncertain, and conflicted situations of practice.” [9]

This is exemplified in the opening 10 minutes as electronic musician Martin Slawig performing from Braunschweig, Germany illustrates “intuitive knowing” and awareness of spatial orientation to musical concepts, “I played a cymbal *in* time but *lost* timing inspired by the section before [...] I liked the *growth* of this moment because of the multi-layer patterns and rhythmic *speed up*, everything was there, guitar loop, bass pulse and at 12’34” *brake down* everything *deleted* and *flatline*”. Slawig is describing a section of group dynamics where the music and visual mixing build to a climax, and then suddenly drop. Sensing this same collective crescendo, Turkish bendir player Yavuz Uydu remembers, “I start playing an increasing metered 2/4 beat, I think this is what triggered everyone to *build up*”. Although most of the live cinema artists reported a cognitive priority to the visual mixing before the music, Helen Varley Jamieson also related an awareness of spatial metaphor to concepts in her strategies during the performance, “I consciously chose images that spoke to the theme in some way [...] to include the idea of temporal distance as well as spatial”. Contributing to this, fellow visual collaborator Graziano Milano notes, “it’s timbre, tonality, pace, atmosphere, melody that triggers in me visualisations of what kind of general mixes/visuals may work”. The author also argues that timbre plays a pivotal role in the perception of meaning in intercultural, and interdisciplinary improvisation. Sacks (2007) also suggests, “timbre constancy is a multileveled and extremely complex process in the auditory brain that may have some analogies with [visual] colour” [10] and this is corroborated by examples where qualities of sound appear to guide participants perceptions of audiovisual events. What starts to emerge in these statements is a relationship between metaphorical signification in sound and the creative responses of collaborators to it.

Conclusion

Distant Presences is an illustration of a successful cross-cultural interdisciplinary collaboration, achieved by combining audiovisual interfaces for an innovative performance outcome. It demonstrates the creative and cognitive challenges facing musicians and visual artists who foray into the liminal collaborative terrain of live, improvisatory, networked performance. Approaches to audiovisual improvisation are discussed and chosen examples illuminate the role of metaphor in signifying meaning in intercultural, collaborative perception and creative interaction. Evaluation of gesture within the non-visual network performance environment suggests that collaborators replace visual signifiers with extended listening practices, in which melody, rhythm and timbre become entities of meaning, fashioning metaphors of experi-

ence and expression in the minds of the participants. Viewed through a perspective of distributed cognition, visual representations of dispersed collaborators primarily act as “material anchors” [2] for the “conceptual integration” of “a shared physical and socio-cultural human experience.” [2] These representations are also present in the networked environment as interface text boxes or moving cursors.

As a model for cross-cultural collaboration, networked improvisation is unprecedented in its ability to create dialogical exchange between musicians and artists from diverse traditions and cultures. While developing technologies can facilitate these unique experiences, collaborators are faced with new creative and cognitive challenges in negotiating synchronous intercultural improvisation. This paper is intended as a contribution towards an understanding of dispersed cognition and the nature of representation in non-visual networked improvisatory performance, recognizing the need for new methodologies to mediate these emerging topographies.

PERFORMATIVE ENCOUNTERS IN MEDIA ART: AN UNSITELY AESTHETICS

MARIA MIRANDA

Traditionally public art has been associated with work that is, to quote Claire Doherty “permanently sited, monumental and commemorative.” I present work that is made for and in public space but in contrast is neither monumental nor fixed. They work simultaneously across a number of sites, both online and offline, and utilize a range of media strategies. These practices create a different aesthetics that I call unsitely.

Traditionally, public art or art in public spaces has been associated with work that is, to quote Claire Doherty “permanently sited, monumental and commemorative.” Today I will present and discuss work that is made *for* and *in* public space but in contrast to these descriptions or definitions is neither monumental nor fixed. Rather the practices I am concerned with play out in public spaces, including the internet, but are not considered public art. They work simultaneously across a number of sites, both online and offline, and utilize a range of media strategies and interventions. They are ephemeral, networked and performative and through their mobile and ephemeral nature they create a relationship to their audience that is profoundly decentred and asynchronous. In presenting us with such different forms of engagement they are, of course, creating a different aesthetics - an aesthetics that I call 'unsitely.'

Before presenting the artworks I will briefly outline three of my key terms, these are: unsitely aesthetics, network culture and performative space.

Unsitely Aesthetics

In my PhD research I developed the term unsitely aesthetics to refer to recent work that plays simultaneously across sites, both online and offline. Unsitely refers to works characterised by their disruption of traditional approaches to site and by their unsightliness. They can often utilise a DIY approach unconcerned with issues of beauty or traditional notions of spectatorship – sometimes inciting laughter and humour to get at something else. In this sense it is a pun, referring to both the unsightly or unspectacular nature of the work while at the same time pointing to the rich history of site specificity in contemporary art. That is, unsitely pivots on the traditional history of site – from the site/nonsite of Robert Smithson’s “Spiral Jetty” to the decades long experience of site-specificity – Miwon Kwon’s book “One Place After Another: site specific art and locational identity” is an exemplary guide through this tangled and contradictory history. [1] In this way site-specificity is folded into the notion of unsitely, both acknowledging its importance and unfolding a new moment as network culture disrupts our common notions of place and of being in one place at one time. Unsitely refers to the paradoxical multi-sited-ness and situated-ness of these uncertain practices – thus calling attention to their lack of presence in any traditional sense, but rather calling upon a more “horizontal logic.” [2]

The ‘un’ in unsitely resonates with Freud’s notion of the uncanny or the *unheimlich*, in particular the uncomfortable and the ‘not at home’ feeling, which some work evokes, and that can provoke the question of ‘where’ is the work as well as ‘what is the work?’ This sense of the *unheimlich* can produce

both unease as well as an attendant laughter. Following John Dewey and his notion of art as *an* experience, unsitely/unsightly suggests a shift away from a focus on the visual to work that invites participation or engagement through media. [4]

Network Culture

The second important term is ‘network culture,’ a term I have borrowed from Kazys Varnelis. [3] With the growth of the internet and mobile telephony across the world we are witnessing new configurations of public space and public culture. In his conclusion to the book “Networked publics,” Kazys Varnelis describes this new state of affairs as “network culture” and argues that network culture has replaced the logics and periodisations of both modernism and postmodernism. For Varnelis, network culture describes a world where there is a simultaneous superimposition of real and virtual space, many-to-many distribution, peer-to-peer social networks and participatory media. These are the salient conditions of network culture, a paradigm shift away from the commonly understood idea of the information age. As Varnelis argues, today “the network has become the dominant cultural logic” replacing the digital abstractions and reductions of pure information with networked relations. [5] Following Varnelis I consider network culture as the context for the uncertain art practices I will present – as well as the context for the performative tendencies that characterise unsitely aesthetics.

Performative Space

The last term that I will briefly describe is ‘performative space.’ In his book “Loving Big Brother” John E. McGrath outlines an alternative way of understanding surveillance than the traditional account of crime prevention or the traditional critique which posits surveillance as either an invasion of privacy or part of the apparatus of a spectacularised society intent on total control. [6] Instead, McGrath proposes a surveillance space – this is in contrast to the common idea of the surveillance image – where public and private are no longer appropriate terms and our relationship to it is performative. Following McGrath’s argument for a more productive understanding of surveillance through the notion of performativity I’d like to suggest that our current condition encapsulated in the term network culture is creating a performative space of encounter.

The Projects

MTAA

The first project I will present is MTAA’s “One Year Performance Video (aka samHsiehUpdate)” from 2004. This work shows immediately the enormous shift in practice and aesthetics from traditional performance art of the 1960s where the presence of the body was of supreme value, to the layered and networked sense of ‘presence’ we live with today. As James Meyer suggests, it was the expansion of telecommunications and increasing mediation that brought forth the well-known 1960’s obsession with presence.

Presence became an aesthetic and ethical *cri de coeur* among the generation of artists and critics who emerged in the 1960s, suggesting an experience of actualness and authenticity that would contravene the depredations of an increasingly mediated, “one-dimensional” society. [7]

MTAA's elegant and humorous project demonstrates this shift not only in art practice but also in the larger social world where the idea of presence and what is "live" have become blurred, extenuated and layered. Media is now part of the everyday to such an extent that the once easy separation between (authentic real) life and the mediated is quite impossible.

In the early noughties MTAA (M. River & T. Whid) made a series of works called "The Updates." These works riffed on seminal performance art from the 1960s and 1970s, "updating" them for our current networked era. The update "One Year Performance Video (aka samHsiehUpdate" reworks Sam Hsieh's "One Year Performance 1978 -1979 (aka Cage Piece)." Like the logic of Liam Gillick's 'What if' scenario-thinking it asks, what if Tehching Hsieh made this piece today, in the public space of the Internet? [8]

In the original work by Hsieh, the artist lived in a cage for an entire year. The cage was built in his downtown New York studio. Hsieh committed himself to a regime of extreme deprivation where for the entire year he didn't talk, read, listen to the radio or watch TV. To pass the time he took photos of himself and marked the wall of his cell – like a prisoner in solitary confinement. His physical needs - food and sanitation - were attended to by an assistant "with whom he did not exchange words." In contrast to MTAA's Update, the work was enacted in an essentially private space, that of the artist's studio, with no audience. MTAA's update was commissioned by Turbulence in 2004, and has been available online since then. However, whenever you access this work the artist statement announces the date you logged on as the start of the work. In other words, the work begins when each viewer commences to view the work.

For MTAA, the work has shifted from the "act of living in a cell" to "images of ourselves living in a cell."

We've transferred the onus of a 1 year commitment to the work from the artist to the viewer. The piece will be realized fully only when a viewer runs it for one year. ... In the work, we mimic endurance without doing the labor. We also know the audience can just close the browser and walk away. No one needs to suffer on this one. [9]

This is a crucial shift – but doesn't necessarily mean that mediation is merely the viewing of images. If McGrath is right, rather than images this performance creates a performative space between the viewer and screen events – one that is open to possibilities, just like Austin's happy performatives. This sort of media artwork accessed and experienced through the internet can be understood as creating a performative space. This is distinct from previous understandings of the internet as cyberspace, where the internet was a separate space apart from everyday life, a space that took you into another realm. Instead MTAA's updates operate as a constantly dynamic space of play, and one which sits beside or even inside the everyday domestic and work spaces of one's life. As McGrath points out in relation to "uptake" and surveillance space, there is a productive gap between the work and the person experiencing the work, thus allowing for an open and dynamic relationship rather than a closed work of set meanings or merely documentation of past events. It is this gap that is productive, as it creates the possibility for a space of performativity "a space between the possibility of sense and the possibility of tyranny of sense." [10] In other words it brings a sense of freedom from the tyrannies of representation that call for absolute truth.

With MTAA's straight-faced performance new questions arise. What is the relationship of audiences to online distributed work? What is the value and importance of documentation historically and today as it is being reconfigured with online performance? And crucially the work throws out a challenge - is this a documentation or a 'live' performance? What can 'live' mean in such a mediated situation where the

time of the performance is totally separate from the time of the viewing? The dislocations and performative nature of the work that these questions imply also make this work unsitely – its existence dispersed across time and space.

NEVER BEEN TO TEHRAN

In the project “Never Been to Tehran,” Andrea Grover and Jon Rubin invited twenty nine international participants to contribute photographs of the city of Tehran as they imagine it to look – on the condition that they themselves had never been to Tehran.

Imagine a city that you've only seen in reproductions or perhaps have merely heard about. A place, like many others, that only exists for you through indirect sources & media; the nightly news, hearsay, literature, magazines, movies, and the internet. Using these second-hand clues as firsthand research materials... Contributors will upload their photos daily to an on-line photo-sharing site, which will be projected as a slideshow simultaneously in galleries and public spaces around the world (including Tehran). [11]

This project utilises a sort of reversed site-specific logic where participants imagine a place, a specific place that they themselves have never seen or visited, through another place, which is their own. In contrast to the previous work where the visibility of the artist was a central pivot of the work, the artist is not visible in these photos. Rather than the artist's body as a phenomenological body of presence, this project works from and through the many different artists' global positions that make up the mosaic of images. The photos, all 408 of them, evoke a place through landscape, decorative motifs, ephemeral objects from daily life, the flotsam and jetsam of the everyday as well as the monumentally built environment. It is a networked collaboration that creates a dynamic shifting mosaic of images of not just an imagined Tehran, but conversely, of the people and places that participated. The specificity of where-in-the-world each image was taken is highly significant. In the work, Tehran can be the stony mountain landscapes of New Zealand, the deli windows of Brooklyn, the carpet sellers in Italy, the diamond-shaped paving stones in Denmark, or stacked supermarket shelves in Japan. This very tension between the pictured Tehran, the imagined Tehran and the 'real' Tehran can create, for viewers not in Tehran, a range of responses – at times the images evoke a sense of the absurd, they can seem uncanny, artful and inventive, wistful, melancholic or simply delightful and oftentimes they provoke a laugh out loud response. In this way the images are obviously not 'real' representations of Tehran, rather they perform the place called Tehran by calling forth images and scenes from the immediate world of each artist, in a non-stop kaleidoscope one could call 'performing Tehran.'

SEARCHING FOR RUE SIMON-CRUBELLIER

The last work is a work I made in collaboration with sound artist Norie Neumark called “Searching for rue Simon-Crubellier.” It is the first project in a trilogy of work exploring actual and imagined relations to place and in particular mediated, networked public space through performative encounters. It was begun in Paris in 2004 while on a residency at the Cité International des Arts.

“Searching for rue Simon-Crubellier” takes as a point of departure the experience of being Australians in Paris and reading George Perec's book “Life a user's manual.” In this book Perec creates a puzzle of a novel set in a building located in the 17th arr. at number 11 rue Simon-Crubellier. Early on in “Life a

user's manual" Perec describes in detail exactly where this street would be. [12] Following Perec's directions we set out from the Cité and began our search in the 17th arr. In the first part of the work we 'performed' the encounters of Australian travellers in a foreign place looking for a particular street by stopping strangers in the street to ask directions. We were directed to one official location after another – the local council, the national archives, the library of maps, the planning department etc, until a month later, we ended up at Boulevard Morland, one block from the Cité, at the Commune de Paris in the department in charge of map-making for all of Paris.

In the course of this project – it was a month long process – we came to understand our ongoing activity as “performative encounters,” rather than performance art or conceptual art, and the video and audio material as no longer to be considered material just to make a work later – it too was the work. In a sense we were not documenting a separate event. The documenting was the event. It was at this point that the significance of media in public places became apparent. We realised that the media we carried was essential to having these sorts of encounters, and the audio and video apparatus created a performative space of encounter. For McGrath, non-performative representations allow the viewer an external relationship to the represented via representation, performative space brings the viewer into the space constructed. As in performative language, ... the space does not exist without the viewer/auditor's implication.” [13] And so it was with us.

This project has been exhibited several times, displaying the accumulated artefacts of its ongoing search, which makes each exhibition of the work distinct, prompting the question ‘where is the work?’ Is it the performative encounters on the streets of Paris? Is it the online Google searches that are undertaken for each exhibition? Is it the exhibition of the accumulated artefacts? The performative encounters invited people to play for a moment. It was an intervention into public space, yet we didn't consider it a participatory project. Rather our interest was in the possibilities of encounters with strangers – thus performing our own sense of Paris, in other words *performing Paris*.

In Conclusion

In using the art historical term “site” to understand these works that are now playing out across public space, including the internet, I want to point to a paradox that looms into view in both current practice and our actual lived experience – the paradox of being in a place and not in a place; of being located and elsewhere at the same time. I have used “site” to focus on this paradox as on the one hand it foregrounds the lived experience rather than the technology, and on the other it troubles the notion of “place” as it is used by writers intent on a singular or essential relation with place. Although site suggests a fixed place, I am using unsitely to unhinge this fixity and to suggest a troubling and opening of the place of the work of art. Hence I use unsitely to evoke a space of tension, ambiguity and potential.

PLAYGROUND GAMING WITH WII, KINECT AND PROCESSING

Grethe Mitchell & Andrew Clarke

This paper is a case study in the design and development of the “Game Catcher” - an interactive application produced as part of an AHRC “Beyond Text” Major Grant project that uses open source software (Processing, libfreenect) and hacked games hardware (Kinect and Wiimote) to create a low-cost motion tracking system that allows the recording, playback and analysis of children’s playground games in 3D.

Fig 1. Hand positions in a clapping game (© Grethe Mitchell & Andy Clarke)

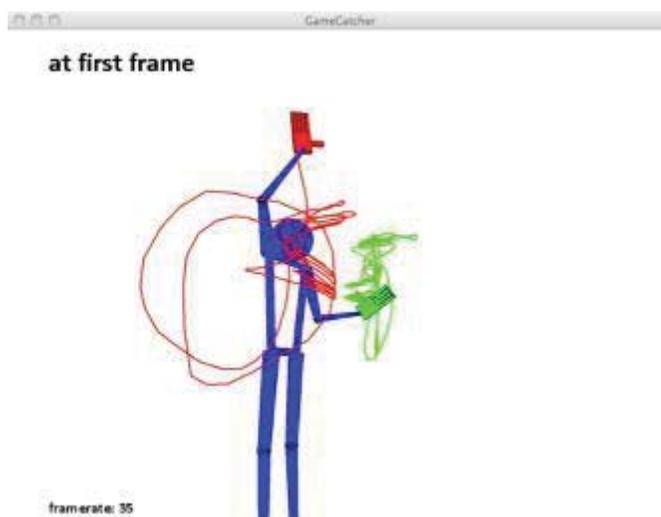

Fig 2. Visualisation of the path of the hands over time (© Grethe Mitchell & Andy Clarke)

INTRODUCTION

This paper is a case study in the development of the Game Catcher, a low-cost markerless motion tracking system produced as part of “Playground Games and Songs in the Age of New Media”, a two-year project funded by a large grant from the AHRC as part of the Beyond Text Programme.

The Game Catcher uses open source software (Processing, libfreenect, DarwiinRemote, OSCeletion, Simple-OpenNI) and hacked games hardware (both the Microsoft Kinect sensor and Nintendo Wiimote) to

create a low-cost markerless motion tracking system that allows the recording, playback and analysis of children's playground games and movement in 3D.

The following paper focuses on some of the technical aspects of the project, particularly the advantages of using videogame hardware and open source software to produce this application. Readers requiring more information on the archiving and visualisation aspects of the application are directed to our other papers [1] [2] and to the project report. [3]

The development of the Game Catcher was supervised by Grethe Mitchell of the University of East London (now at the University of Lincoln), and the final version of the application was developed by Andy Clarke.

PROJECT AIMS/CONTEXT

Recording movement for archiving and analysis is a common task in the Arts and Humanities. Approaches include written descriptions and drawing. Video recording technology is also commonly used, but although it is cheap and easy to use and therefore has advantages at the recording stage, it is more cumbersome when it comes to analysis. For instance, it may leave some details lost (though being out of shot, filmed from too far away, or obscured (either by the subject's other limbs or by other participants). Motion capture has many advantages over video, in that it allows the movement to be viewed from any angle or distance, not just the one that it was recorded from. There are, however, also negative aspects – such as price, availability, and the complexity of configuration and operation – which make them generally unsuitable for use in Humanities research projects.

We felt that a low-cost markerless motion tracking system would be able to combine the price/ease of use of video with the benefits of motion capture. Also, having researched and written about the appropriation of videogame hardware and software, [4] we felt that the new forms of motion sensitive videogame hardware (such as the Wiimote) could be adapted to form the basis for such a system, particularly as this approach would build upon the other advantages of videogame controllers such as an extremely favourable price to performance ratio, easy availability, robustness, familiarity with users, and so on.

The Game Catcher was developed as a fully functional proof of concept application, designed to address the preservation, visualisation and archiving of movement and to fill this price/performance gap between video and motion capture. In parallel, we also wanted to create a playable game which would allow a child to record their (movement-based) game and then play "against" this recording. Our aim here was that the computer game and the research tool could form a virtuous circle, with the playability acting as a reason for children to keep playing with the Game Catcher, thereby also providing more data for the researchers. The process of making the Game Catcher playable as a game also made us look at the issues involved in bringing "real world" playground activities into a computer environment, and made us think more consciously about what makes real life playground activities – and computer games – enjoyable.

TECHNOLOGY

To fulfil its stated aims of allowing the recording and playback of clapping games, the Game Catcher had to perform two different tasks: (a) track the position of the hands in 3D space; and (b) detect the orien-

tation of the hands. From this information, the path of the hands could be determined (and reconstructed in “playback” mode) and claps could be identified – whether they were player to player, player to computer, or computer to computer claps. This all had to be done with a sufficiently high frame rate and accuracy, and sufficiently low latency, for the data to be useful as research material and enjoyable during play. In addition, the Game Catcher had to be usable by researchers “in the field” – meaning that it had to be simple, robust, not require an excessive amount of technical knowledge to set up and use, and provide resilient tracking under a variety of lighting conditions and environments.

Processing was chosen as the programming language for the Game Catcher because of its ease of development, its focus on creative computing, and its extensive collection of pre-existing contributed libraries (and active development of new ones). If we had needed a C-based alternative, we would have probably used OpenFrameworks, for the same reasons.

During the course of developing the Game Catcher, we used a number of different solutions before adopting a “best of breeds” approach which used the Kinect sensor to track hand position and Wiimote controllers to track hand orientation. This proved ideal, exploiting the strengths of each system. One of the issues that we came across (and perhaps failed to fully appreciate in drafting the proposal) was the difference between a controller like the Kinect that does motion tracking and one like the Wiimote which is merely motion sensitive. The Kinect detects hand movements by tracking changes in their position whereas the Wiimote only senses changes in acceleration and therefore has no idea of where the hand actually is.

The Nintendo games are designed to minimise or conceal these limitations, but no such workaround was possible with the Game Catcher. As a result, it was necessary to adopt a hybrid approach which used the Wiimotes for the task that they were most suitable for (determining the hand orientation) and explored alternative solutions to the issue of tracking where the hands were in 3D space. This gave the Game Catcher a theoretical performance of around 3mm in the XY axis, 1cm in the Z axis and 1° in orientation. In practice, unavoidable system noise in the Kinect depth map reduces the XYZ accuracy slightly from these ideal figures, though it still remains well within acceptable levels. The accuracy with which depth is measured varies, and when an object is far from the Kinect, its movement is measured in larger steps than when it is close. The figure for orientation is likewise the raw measurement and in some hand orientations the Game Catcher makes the hand snap to 90° to avoid gimbal lock issues.

The authors have previous experience in video tracking, having used applications such as STEIM BigEye and Danny Rozin’s TrackThemColors Director xtra within the context of dance and technology. As a result, they were aware of the shortcomings of video tracking – being too easily affected by outside conditions such as the brightness and colour temperature of ambient lighting or the clothing of participants.

As a result, we rapidly switched to an innovative approach which used Wiimotes not only to sense the orientation of the hands, but also to track their position. We attached an infra red LED to the Wiimotes in the player’s hands and used a third Wiimote as a camera pointing at the player to track the position of these LEDs. The advantage of this approach is that it is very fast as the Wiimote has a dedicated chip optimised to do this image analysis in hardware. The tracking is also robust and resilient to lighting conditions, etc. as it is tracking infra red light, rather than visible spectrum. The LED point source does not allow tracking depth and we therefore planned to use triangulation to determine distance, an approach demonstrated by researchers at the University of Cambridge. [5]

Although the Kinect was hacked on its first day, it took a while before Processing libraries by Daniel Shiffman and Paul King became available. These only provided access to the raw depth map, not to the

player skeleton, so bespoke hand tracking code was necessary. This approach provided an extremely high framerate – up to 100fps, even when tracking two hands – though self-occlusion was an issue, with the tracking becoming confused and tracking the wrong body part when, for example, a hand was temporarily hidden behind the other arm.

Because of this, we switched to OSCekeleton as soon as it was available as this provided access to the player skeleton. OSCekeleton ran as a separate command line program, communicating with Processing using the OSC protocol. This added additional complexity in setup/use and was felt, in the end, to be inappropriate for the Game Catcher if it was, as intended, to be useable by researchers in the field. For instance, when OSCekeleton experienced a segmentation fault, this could leave both it and the Game Catcher frozen. We therefore switched to the Simple-OpenNI library.

As both OSCekeleton and Simple-OpenNI can track multiple users, we developed and tested a multiplayer version of the Game Catcher, focused on other movement-based playground games such as skipping, hopscotch, dance routines etc.

ISSUES

There were a few issues with the Wiimote from a technical point of view. It does not, on its own, track rotation about the Y axis and suffers from a gimbal lock problem when pointed vertically upwards. This meant that we could not distinguish between two key hand positions: the palm out, fingers up (position 3 in large image) and the similar position with the palm facing sideways (position 5). In addition, the rotation could flip uncontrollably by 180° when the hand was in these positions.

Normally, the Wiimote relies on the Sensor Bar and/or the Wii Motion Plus to solve these problems, but neither was suitable for the Game Catcher. The first would require the user to keep their hands pointing at the bar, which clearly unsuitable for a clapping game, while the latter added too much additional bulk and weight.

An alternative approach was used. By paying attention to the previous position/orientations of the hands and the limits of human anatomy/physiology, we could add an additional level of interpretation to the raw data received from the Wiimotes and eliminate hand orientations which were either physically impossible or made no sense given the context of a clapping game. For instance, when the hands are vertical (fingers pointing up) in a clapping game, it is unlikely that the player's palms are facing their body as this is not a common move and even if they were in this "palms facing body" pose, they would have gone through some clearly identifiable intermediate positions to have arrive here.

This "filtering out" of non-used positions in the electronic environment is one of our "design solutions" of the development, based on the "perceived affordances" [6] of the system and the properties and affordances of the clapping movement ("real" and electronic), as well as on the affordances of the "real world" environment.

The other main technical issue that we faced was the relative weakness of Processing in rendering certain types of 3D graphics. In computer games such as the Wii Sports boxing game, the player's avatar is seen from behind in a ghostly form. This is an established convention which we wanted to use in the Game Catcher when the player is clapping with their recording, but we found Processing unable to render the semi-transparent 3D graphics needed for this effect. A workaround, using a wireframe avatar was felt to be sub-optimal.

The Wiimotes are convenient for holding, but are a little large to be comfortably mounted on gloves (so as to track clapping, for instance). Having done our prototyping using the Wiimotes, we are now looking at using the Seeeduino Film to engineer a smaller alternative.

VISUALISATION AND ANALYSIS

The raw movement data is saved in a plain text format and records the X/Y/Z/roll/pitch/yaw of every body part in every frame along with a timestamp (a sound file is also recorded of the clapping rhyme/song which plays back in sync with the movement). This data file is used in replaying the game, and is also designed to be easy to analyse. The Game Catcher provides an example of this analysis, having a built-in “visualisation” mode (see small image) which shows the path of the hands throughout the entire game. This image can be rotated and viewed from any angle and played, paused and rewound at will.

A natural extension of this would be to be able to view two recordings side by side for comparison or to superimpose the paths of one recording over another. Both of these would assist greatly in identifying similar clapping games or spotting when a variant of a game has emerged. Currently these are difficult, time-consuming, tasks relying on the manual comparison of video recordings, which may have been taken at different angles or be of clapping games performed at different tempos.

Computer analysis is also possible. Identifying clapping games from the analysis of video footage is complex, [7] but doing the same from motion data (such as that collected by the Game Catcher) is feasible as claps can be identified from changes in the velocity of the hands, changes in direction, or proximity to one another. These same principles and solutions can be applied to many different movement-based activities.

CONCLUSIONS

The Game Catcher is a fully functional prototype, working both as a computer game and as a research tool. It has proven the viability of a tracking solution “in-a-suitcase”, an exciting development as it means that ephemeral movement data can be captured, analysed and conserved at low cost, without extensive technical knowledge.

This has interesting outcomes for research in the Arts and Humanities. In terms of development, the Game Catcher allows for a low-cost visualisation mechanism allowing performers of all types (dance, music, theatre, circus etc) to see the shape and position of their activity in 3D space, thus opening up new avenues for artistic development and performance improvement.

In terms of research, the Game Catcher is particularly interesting to the arts and humanities disciplines, where research often takes place in-situ, rather than in a pre-determined, specially designed space as is the case for some medical or sports movement research, or in the entertainment sector (e.g. film and videogame production) where high-end (and expensive) motion capture studios are commonly used.

The above outcomes – and overall process of developing the Game Catcher – have led us to consider more deeply how movement is studied across disciplines, and whether these techniques are shared. From our research, it would seem that the techniques for recording and documenting movement are patchy, with bodies of knowledge siloed within certain fields and little known (or little used) outside of that particular field. For instance, formal movement notation systems such as Labanotation are used

within dance, but not outside of it, even though it could have application elsewhere. Commercial motion capture systems are likewise used in the entertainment industry and in high-end medical or sports research and development, but are not generally used in the arts and humanities.

A follow-on project by one of the authors (Grethe Mitchell), also funded by the AHRC, is addressing this issue. It will organise a symposium and book allowing the exchange of best practices across all disciplines with regard to the recording, analysis and archiving of movement-based activities (in all their forms).

NEW AESTHETIC ENERGY INFRASTRUCTURE AND THE LAND ART GENERATOR INITIATIVE

Elizabeth Monoian & Robert Ferry

The Land Art Generator Initiative addresses public art within the urban fabric of the sustainable city. The goal of LAGI is to design and construct a series of large-scale site-specific installations that combine art with utility-scale clean energy generation. The artworks utilize the latest in renewable energy science and innovate the application of new technologies. www.landartgenerator.org

Imagine yourself walking in a large park at the edge of the city. In the distance, an object appears to rise organically from the landscape. Its armatures and folds relate to the composition of the setting. Looking closer, the large object makes you think of the complexity of patterns that exist in the natural world while at the same time it inspires an awe of human invention and ingenuity. The geometries of the sculptural elements seem to respond to the sun and the wind.

When you reach the observation platform the vision comes into perfect form, like a painting in a frame. As you watch the way that it reacts to the forces of nature, you think about the interconnectedness of human activity with the earth and the delicacy of our shared ecosystem.

You are surprised to learn that the beautiful object that has so captured your attention is also a power plant harnessing the energy of nature in the creation of carbon-free megawatt-hours that are at that very moment providing electricity to thousands of nearby homes. You stay for a while listening to the energy conservation discussion that is going on there that day, stealing glances toward the artwork as it moves to follow the sun.

Is it possible that in the future, all human endeavors could be fuelled by clean renewable energy? And that the systems which generate the energy could be designed to be beautifully and seamlessly integrated into the fabric of our biotic and cultural ecosystems?

While contemplation on the condition of our planet can be dispiriting, it is important to remember that remedies exist. At our most optimistic we can even see ourselves in the midst of a new revolution—one that puts sustainable resource management above planned-obsolescence consumerism.

To get there, we're going to have to convince a great number of people to embrace the ideas associated with the change, clearly understand the need for it, and see its inevitability. This takes a heightened awareness of the cultural drivers of change. The investment in time and economic resources that change requires should be justified in the great return in cultural and economic wealth that the change brings with it.

We've placed our focus on one part of the equation—that of energy generation—because it is critical to accomplishing a harmonious transition and because democratized access to clean energy has the potential to dramatically increase the standard of living of everyone.

When most people think about renewable energy a few things come to mind. We might picture dark blue solar panel arrays or large wind turbines in the ocean and lining mountain ridges. The form of these objects is derived almost entirely from the engineering processes that have made them function more efficiently through each generation of technological advancement. Consideration of efficiency and cost per kilowatt capacity has driven the appearance of renewable energy technologies for two reasons. First, the cost of energy is relatively low in a global market that subsidizes non-renewable fossil fuels and writes off externalities, [1] and renewable alternatives must strive to compete on those terms. And second, large-scale energy generation facilities (i.e. coal-fired power plants) have historically been located far enough away from the city that aesthetics were not of utmost importance.

Functional and mechanical considerations should always remain an important priority of good technology design, and it is imperative that we implement strategies that will ensure universal access to affordable energy. At the same time, we may be wise to question the ability of advances in renewable energy technologies to reach their greatest potential if their physical forms continue to exist entirely outside of aesthetic and cultural considerations. This question is reinforced by the fact that the process of harnessing renewable resources such as the sun and the wind often requires that energy generation facilities be located in more visible locations.

The science of renewable energy may soon find the way to cost parity with conventional fuel resources, and by some measures, they already have. But the popular adoption of new sustainable technologies will require that they have the ability to appeal to people on an emotional level. It will require a popular appreciation of the value inherent within a shift in energy resources and not just of the dangers inherent in not shifting.

Meanwhile, the dangers are quite real. With climate, environmental, and health effects of extraction and combustion on the one hand, and the finite nature of fossil fuels and uranium on the other hand, it is imperative that the next few decades see a rapid transition to renewable alternatives. One of the leading obstacles to greater adoption is the indifference or lack of understanding of policy makers, stakeholders, and community leaders. We therefore should look to all means with which to educate and influence popular opinion.

Every advancement in technology comes with its own complex set of risks and potential consequences and should be well considered ecologically before being applied universally. [2] The incredible bounty of the Earth, if managed sustainably and in harmony with nature's balance, can lead to a heroic triumph over poverty, starvation, and suffering.

Instead, our ability to tamper with the balance of nature and to squander the precious resources available to us has been a tragedy of epic proportions. A short-list of the damage done includes all of the polluting effects of mining and extraction industries, the "resource curse" stifling freedom and progress in post-colonial nations, effects of airborne and waterborne toxins on human health, habitat destruction and species extinctions, wars waged over resources, increased risks to coastal populations, loss of fresh-water resources, agricultural instability, increased desertification and deforestation, ocean acidification, and global economic instability.

This list of 20th century tragedies is in great part due to the historically brief anomaly of easy access to conventional crude oil (~1860-2060). But it also has to do with the corresponding cultural memes that proliferated with and as a consequence of the technological and scientific expansion that was fueled by oil economies.

All along the way art has had a pivotal role to play although it may be often overlooked. In 1909, the Futurist manifesto, [3] along with other contemporaneous movements, gave added momentum to the sentiment of the triumph of man over nature. Europe was gripped by a collective progress-euphoria, as it reveled in the excesses of its scientific and industrial triumphs. It was that same year that humans reached the North Pole, and six years previously the first successful flight had heralded victory over the sky. The world had been mapped and catalogued and ideas about time and space were being challenged. This euphoria of progress is an addiction from which 100 years later we are still recovering. The Futurist manifesto itself was a seduction to the thrilling and fleeting ecstasies that come from narcissistic cultural self-evaluation, environmental destruction, squandering of resources and the waging of war. Above all, its lesson is the ability of art to contribute to change in the world.

While declaring the greatness of speed and progress, Futurism also equally declared the greatness of humanity. But what it did not bring into the fold of its political message was a concern for the well-being of the planet or notions of "humanity" as being defined by a sense of empathy or compassion.

The intellectual profundity of the idea of "Greatness-In-Newness" that was born of those first decades of the 20th century played a critical role in art and design theory that was to follow. On the positive side of the bargain, this grand movement that has seen various iterations and reinterpretations over the last century has consistently questioned the nature of art. The application of its higher ideals has given us the ability to invent spectacular otherworldly creations by fusing together disparate existences into wonderful or shocking manifestations.

On the negative side of the bargain, artistic glorification of mankind's triumph over nature has arguably contributed, if not to the neglect of our obligation to nature, at least to a distraction from it. In the meantime, we have arrived in the 21st century at a somewhat desperate place in which an updated vision of our future may have no place for human life at all on a planet that has been heated up by our combustion and raked clean by our endless mining for metals and fuels in our insatiable and un-moderated quest for speed and convenience.

A countermeasure of serious import to the Futurist ideas of "Progress for the Sake of Progress" and the "Greatness In Newness" has been the dawning awareness, since the middle of the 20th century, [4] of the serious situation that our addiction to unabashed industry and the fast life of unbridled consumption has placed us—and the planet. Artists have been pivotal in expanding this awareness to the critical mass required for action.

This use of art to expose truths and influence solutions continues with the expanding reach of eco-art, environmental art, and art as social practice. Artists are using the tools at their disposal to educate the viewers, readers, and users of their work about the ethical considerations that are so relevant to popular human behaviors. Art and design have been able to enlighten people about a broad range of social and environmental issues and to instill awareness about the products we buy, the foods we eat, and the energy we consume.

In no small part this is being done through art that employs technology, for example visualizations of climate data or air pollution. [5] Technology is being glorified and used in art with a new purpose and with awareness of the potential harming effects of human behavior on the delicate balance of the natural biosphere.

Meanwhile, the growth of social practice art presents a path to overcome the limitations of didacticism. It is good to teach, but the best methods of teaching have always been demonstrative. How can art 'do' as well as 'be'? With the application of social practice to infrastructure art, the 'do'ing certainly implies a partnership with technology.

Renewable energy technologies have the ability to rise to the occasion that is provided by these two conditions of the contemporary art world: social practice and technological integration.

The Land Art Generator Initiative is creating a dedicated platform for public art as sustainable energy infrastructure. [6] The project offers the opportunity for collaborative teams of artists, architects, landscape architects and designers, working with engineers and scientists, to create new ways of thinking about what renewable energy generation looks like and how it relates to the overall fabric of our constructed and natural environments. It calls on interdisciplinary teams to conceive of large scale site specific artworks that provide renewable electricity to the city at a utility scale (equivalent to the demand of hundreds of homes)—offsetting thousands of tons of CO₂ and providing an iconic amenity for the city.

The outcome of the 2010 design competition exemplifies how interdisciplinary teams can come together to create truly innovative and pragmatic solutions. Hundreds of submissions came in from over 40 countries around the world from design teams that included many top international artists and design firms.

The Land Art Generator Initiative has partnered with NYC Department of Parks & Recreation for 2012 to hold an international design competition for large-scale works of site-specific public art for Freshkills

Park (the former Fresh Kills landfill) in New York City, which, once reclamation is completed, will be a cultural amenity almost three times the size of Central Park.

Jurors include: Dr. Henry Kelly, Acting Assistant Secretary and Principal Deputy Assistant Secretary for the Office of Energy Efficiency and Renewable Energy at the U.S. Department of Energy; Bjarke Ingels, Founding Partner of BIG | Bjarke Ingels Group; Patricia Watts & Amy Lipton, Directors of Ecoartspace; the Public Design Commission of the City of New York.

Following are two examples from the 2010 Land Art Generator Initiative design competition that illustrate the potential for innovation that lies in interdisciplinary collaboration.

The Windstalk team, led by Atelier dna in New York City, [7] arrived at a solution to harvesting the power of the wind that had never before been considered. They were inspired by their observation of nature, specifically the way a field of wheat or tall grass blades wave in the wind. Rather than relying on a rotor with blades attached, they conceived of a set of stalks that would move under the power of even the slightest breeze coming from any direction.

By placing piezoelectric generators along the stalk and a torque generator at the base, the Windstalk design has the potential to generate more electrical output per square meter of land area than a conventional horizontal-axis wind turbine (HAWT) array. The reason is that HAWTs must be placed far enough apart so that the wind disturbances and vortexes that each turbine creates in its wake do not affect the efficiency of the other turbines. Windstalks can be placed in close proximity to one another.

An innovative solution for solar power came from the PV Dust project from an interdisciplinary team in London. [8] By utilizing a new solar product called Sphelar(TM) by the Kyosemi Corporation, the team conceived of a three-dimensional array of spherical solar receptors that increases the incident surface area of the installation.

The result is that the design requires 57% of the land area per KW capacity output when compared to an array of flat photovoltaic panels, while maintaining use of the ground for other purposes such as farming or recreation.

These designs go beyond their conceptual and aesthetic innovation to include engineering innovation. But even short of that, the application of existing technologies in new and artistic ways creates cultural innovations, which can be equally powerful as drivers of change.

Because the renewable forms of energy generation such as solar and wind do not pollute in their daily operations, they are more likely to find their way into proximity with residential and commercial neighborhoods. As this has already started happening, there has been some push back from local communities in terms of aesthetics, for example with neighborhoods rejecting wind turbines that they can see from their backyards (the so-called NIMBY effect). [9]

For while such installations do not billow smoke, the argument can be made that visual pollution is no less an impediment to the proliferation of clean energy inasmuch as detractors can point to “not in my backyard” examples of installations that have negative impacts on real estate values and community cohesion.

Cultural innovations via infrastructure art can provide new tools for city planners with which to integrate renewable energy systems into the built environment while addressing such public concerns. And they can provide investors with new opportunities to capitalize on projects that provide multiple revenue generating engines (a power plant that also generates money from tourism for example, or that is partially financed as a cooperative by the community).

We can envision a day when renewable energy generating artworks will add cultural and economic value to public spaces around the world, while giving us cause to feel good about our creative stewardship of the environment.

FROM ARCHIVE TO RETROSCOPE AND BEYOND – PUSHING FORWARD RESOURCE DEVELOPMENT

CATHERINE MORIARTY

This paper presents a chronology of image digitization projects undertaken by the University of Brighton Design Archives and discusses the relationship between this work and archival description in a conventional sense. It suggests a coalescence of, and describes a tension between, information management standards and the curatorial and user innovations that networked archives might provoke.

The Golden Egg Restaurant, London, 1966. (University of Brighton Design Archives).

The intention of this paper was to discuss the outcomes of a collaborative project between the University of Brighton Design Archives and the independent web resource, The Retroscope. However, the project is yet to attract funding and so the following takes the form of a discussion setting out the thinking behind the project and its background. It focuses on ideas about location; of archival photography as described in hierarchical arrangements; as distributed electronically in the form of digital surrogates; and, ultimately – doubling back on itself, so to speak - as the representation of things in the real world at a

particular time and place. It suggests a coalescence of information management frameworks and curatorial innovation of a radical order.

I first saw analogue photographs from the University of Brighton Design Archives represented online in 1999. It was an extraordinary feeling to see these digital images. 100 or so photographs from the archive were scanned for a project in Scotland, the Scottish Cultural Resources Network (SCRAN), and four things struck me immediately: the greater value of our material when located alongside that from other archives and museums; the immediate visibility of photography usually accessible by appointment only; the scale of the potential audiences who could now see it; and, significantly, the importance of place. The latter requires some elaboration.

The photographs contributed from the archive to the SCRAN project depicted Scottish products displayed at the 1947 Enterprise Scotland Exhibition held in Edinburgh. The supporting caption information on the back of each print was incorporated in the metadata of the corresponding digital file and this included the name and address of the manufacturer of each represented product. It became immediately apparent that this information could present a map of manufacturing in Scotland in the postwar years, and that this location data would be of considerable interest particularly to local and business historians. The photographs that had been acquired as part of an archive of design now became re-activated in a new digital environment, with material from other collaborators and as part of a project with a mission to reach wide audiences. Since then, however, the issue of location has re-appeared consistently, sometimes as a dilemma, and more recently as a great opportunity. This paper maps this process.

In a similar way to the initiative described above, subsequent educational digitization projects in which the Design Archives participated involved delivering sets of images scanned from our photographic holdings that were then added to an amalgamation of material from different sources principally the Visual Arts Data Service and more recently, the Joint Information Systems Committee Media Hub. In the agglomerated pools of data offered by these services, we envisaged our images appearing in the results lists of varied research enquiries and reaching audiences with whom we would not have engaged alone. However, an issue that soon became apparent centred on the context of each digital image. For unhitched from the analogue parent, it was difficult to understand the place of the photograph in its home archive; indeed, its archival arrangement – to use the proper term - was never explained. These images were orphaned, detached from their original context and offered-up as separate digital objects.

It became clear then, that the dynamism that digital surrogates of archive photography enjoy is both a blessing and a curse. Indeed, in some ways they seem too free, in that they are removed from their archival hierarchy and presented in a flattened 'chocolate box' thumbnail arrangement, from which the viewer cannot navigate back in order to understand the object in its home environment. In other words, the viewer cannot understand which print or negative is placed before or after it; or how long the sequence is and what its overall purpose was; or, which series or collection group it forms a part of. This is precisely what the International Standard of Archival Description ISAD(G) was established to explain. Building on established principles of archival practice, it is an information architecture that is a flexible matrix, that accommodates a vast array of different multi-level scenarios, from small collections relating to the life or work of an individual, through to the complex structures of huge government departments and their transforming shape over time. Yet though fluid, the ISAD(G) standard has limited possibilities for correspondence or creative linking, in other words, establishing relationships between different archives, and matching a detail in one with detail in another. While the field 3.5.3 'related units of description' can act as a link to associated records, the item, for example a document or a photograph in

its file, or the file itself, and the series in which it sits, and the collection group to which it belongs, remains largely as a self-contained whole. These relationships might be visualized as a tree with numerous main branches, off which smaller branches stem, eventually leading to clusters of foliage made of individual leaves, yet the tree stands separate from others, rather than within a forest, close to and intertwined with its neighbours. Thus, while an ISAD(G) record might sit alongside other archive descriptions, it does not really provide a means of extending beyond itself (in a more creative sense). Despite this, it is undoubtedly the best mechanism for explaining the arrangement of archives and adopting this standard drives a level of consistency at an international level.

At the Design Archives we describe each of our eighteen archives according to the ISAD(G) standard and we deliver these descriptions through the Archives Hub, an online portal to agglomerated archive descriptions relating to British university archives, and other archives outside the sector, numbering 180 institutions in total. As part of the Archives Hub, our multi-level descriptions of each archive unfold beautifully before our eyes replicating how the material was originally generated or collected. By clicking on ‘full record’, the top-level collection description can be seen to have several sub-sections or series that then, as one clicks on the folder icons, reveal further nested sub-sections, and each of these, further files within, that can be opened-up, right down to item level, i.e. we can see, for example, the place of the photo in the file alongside all its neighbours. Even more of a development is the way in which, during the past year, the Archives Hub has introduced the capacity to attach digital images to item-level records, so we can see the photo alongside the description of it. This means it is now possible to attach the Design Archives images produced for other digitization projects (by this time we had amassed a collection of over 6,000), to the correct place in the archival hierarchy, so viewers can see their proper arrangement. This re-attaching of the orphaned digital images to their archival context represented, certainly for the Design Archives, a dramatic alleviation of the symptoms of disassociated digital objects. Yet, this being the case, it raised another idea for it makes clear how the viewer cannot jump from the item level record to explore the greater context of what a particular photograph or document represents. We see the micro-geography of its archival arrangement (its local context as object) but however detailed the scope and content description, we cannot appreciate what this image represents in time and space, i.e. the macro-geography of what it represents, we cannot put it back in its place in the world.

In order to develop this idea, an example might help. In the archive there is file of photographs relating to each edition of the periodical ‘Design’. The February 1966 issue of the magazine included a feature ‘Eating Can be Fun’ with some highly evocative colour images of the Golden Egg restaurant located in London’s Leicester Square. In 2001 some of this photography was digitized and included in an online learning resource, one of seven published by the Design Archives as part of the project ‘Designing Britain’. [Fig. 1] Authored by Matthew Partington, the photograph of the interior of the restaurant was included in a study of British crafts of this period, and the project placed this image in a new context, it had escaped, so to speak, from the box of 1966. How, now, might this action be developed beyond conventional research methodologies? Might there be a way to re-conjoin other digital objects relating to Leicester Square in 1966? Might there be a way to place this object alongside other represented moments, and see what else was happening at the same time, in the restaurant, or across the road, or elsewhere in London, and if we had a photograph of a visit to the restaurant, or a scan of a diary entry or of a receipt, could there be a way to bring these objects together? Could there be some type of digital environment, a matrix or mesh, which facilitated the space and time curation of digital objects? Might there be a way to create a more poetic navigation of digital objects beyond the frames of information management? Indeed, how could we use the indispensable organizational frame of ISADG as a jumping off point? While images or items accessible from a portal harvesting data from many collections might be

searched by time and place 'Leicester Square, 1966', it still would not be possible to perceive the spatial relationship between them. And it is the spatial that is, it seems to me, a critical element in how the past is perceived. Jorge Luis Borges, in 1941, wrote of time in a spatial sense and in a way that presages the potential of digital environments, 'That fabric of times that approach one another, fork, are snipped off, or are simply unknown for centuries, contain *all* possibilities.' Indeed, the theme of time and space is taken up in various places in his writing as a means of challenging perception, and it is this concept to which, I believe, Chris Wild is alluding when he describes his project, the Retroscope, as a 'perception'. And it is to this that we now turn.

By 2011, to recap, the Design Archives had created several thousand digital images from one of the largest libraries of industrial design photography in the world. Now, in the process of being added to their respective archive descriptions on the Archives Hub, the digital images are no longer disassociated from their context. But continuing to repurpose and re-arrange these images to enhance their research and learning potential remained an ongoing ambition. Early in 2010, a proposal entitled 'Design Mesh', with the aim to reconstruct electronically one of the pavilions of the 1951 Festival of Britain site as a frame for positioning digital archive objects, was discussed with the staff of the Visualisation Unit at King's College London. Though nothing more came of the idea as a collaboration with the Design Archives (the project was taken up by students later in the year) a colleague who learned of this proposal arranged a meeting with Chris Wild who was busy working on an idea called The Retroscope, a 'visual time machine' that intends to offer a way of surfing time online by integrating images, moving images and sound in chronological and spatial arrangements for people to explore, add to and curate.

The Retroscope is a development of the Retronaut website which since it was established in 2010 has had more than 1.4 million page views per month. While the Retronaut site delivers content (largely images and film) from one source at a time in a conventional editorial format, the aim of the Retroscope is to bring material from different archives together and to facilitate the potential coalescence of their holdings in a dynamic user-driven environment. The project has attracted the interest of many leading archives, including Getty's Hulton Archive, the Bridgeman Art Library, the Central Office of Information and the BBC. Attracting a great deal of attention, it was described by Ed Vaizey, Minister for Culture as 'the next big thing' and by John Mitchinson, Director of Research, QI as 'one of the richest uses yet for the web'. This was exactly the type of project that could move on how the digitized material from the Design Archives was searched, rendered and indeed, curated. Collaborating with the Retroscope suggested a way in which a University collection could work outside the educational sector to extend its visibility and currency and to make more porous the perceived boundaries between conventional educational environments and other, more public, less formal, venues for learning. Indeed, joining forces with The Retroscope would present a high prolife opportunity for Design Archives resources to reach audiences unimaginable alone. We were curious about the advances in digital curation this might bring about, and the convergences between things that have led separate lives until now. What might this mean for arts education and research and for cross-sector dialogue? How could the placing of archival data in a shared spatial and chronological delivery environment (as opposed to the rigid conventions of archival hierarchies) inform new thinking in the arts and humanities? How might a collaboration of this kind provoke research challenges and opportunities? Already, as part of the JISC-funded Media Hub project we had started to add location data to our metadata and were interested in the possibilities of mapping and GPS technology. In 2010 we received funding from the Arts & Humanities Research Council for a doctoral project with the Chartered Society of Designers which centred on mapping membership data. What would happen, we wondered, with an information architecture, a tool such a Retroscope, that invited user participation in such a way that the unofficial would meet the unofficial. Here, it seemed, could be a project where none of the outcomes are prescribed, or could be predicted, where dormant

possibilities might emerge. Indeed, the National Archives in the UK, are busy considering the possibilities of mapping, or 'space exploration', among its suite of 'Labs' projects where various rendering options are being trialed. Will it be the case then, that the common elements of these systems, connected by their locational data, might one day converge, that the Retroscope could overlay the National Archives map, or the National Archives 'Digital Vaults' project in the United States, and that others could overlay these, and we could experience those multiple, forked stories, that excited Borges seventy years ago, that have inspired our sense of possibility, and which technology is now partly able to facilitate.

THEORIZING NEW MEDIA IN A GLOBAL CONTEXT

SORAYA MURRAY

New media provides contexts for global-scale interaction, but theorization around new media rarely intersects with globalization discourses. In a field largely driven by technological innovation, critical theory may be seen as unproductive and thus extraneous. This paper examines the intersection of digital media's practice and criticality, moving away from theories of form and procedure, and situating its scholarship in a global ethical context.

Few contest the idea that advanced computational and communications technologies play a definitive role in today's global economic, social, cultural, political and even ecological orders. The evidence of this exists in technologies used to implement the internationalization of management, the globally shifting labor pools, the enabling of a cosmopolitan managerial elite, transnational banking and other such signs of economic globalization. It lives as well in social, political and cultural manifestations of globalization such as WikiLeaks and the social-media fueled Arab Spring.

While new media forms have a transnational impact, and profoundly influence globalization, one sees little critique or consciousness around issues of globalization as the context in which new media discourses take place. What is the disconnect between new media's global impact, and new media's discourses, which maintain little engagement with theorization of larger social and ethical concerns? In the context of rapid technological evolution, should the study of digital and electronic culture mirror ethical concerns, given the urgent social and political work that needs doing in the world? For example, universal rights discourses might be one key area where computational and communications technologies have contributed to major shifts by increasing the fluidity with which global subjects move across traditional nation-state borders, in keeping with shifting international demands for both the managerial class and labor. Considering the rights of diasporic, transnational and migrant subjects requires greater attention as their global numbers increase.

How can these and other issues of social uplift extend to an area that is fundamentally concerned with perpetual innovation, and often situated in a profit-oriented context? If we are to attempt an approach to electronic and communication technologies that contains within it a self-critical apparatus for contemplating the effects of those works we make and use, then what critical tools can we implement to greatest effect? Moreover, is the discourse of digital media the place to advance these and other theoretical concerns? I should make clear that I make this critique on the meta-level; it is not aimed at individual artists, many of whose works persistently address the important questions of their day. New media is not a unified discipline, but what one might more generally call an 'area' or 'movement' in scholarship, but it does possess a kind of centripetal pull of ideas that requires careful consideration 'as though it were' a discipline. This discussion is aimed at the level of discipline, and to safeguard the future relevance of what we as new media scholars do. Innovation and profit does not assure lasting significance, and in this regard our fledgling movement has serious problems.

This conglomeration we call "new media" is a truly interdisciplinary undertaking that has no fixed academic home, and by extension no organized intra-disciplinary self-regulating value system or ethics – in other words, no cohesive philosophical discourse. D.N. Rodowick's *Reading the Figural* [1] and Mark Hansen's *New Philosophy for New Media* [2] and the interventions collected in CTheory.net form three

examples of scholarly interventions into philosophical engagement with new media, but these are asymptomatic of the more dominant practice-oriented sector of new media scholarship.

In 2008, the worth of theory for digital media was explored in a public discussion between Ian Bogost and Jay David Bolter at the Georgia Institute of Technology. During this debate, entitled, "The Value of Theory in Digital Media Studies," both scholars pointed to the fundamental tension between what Bolter identified as the "procedural" side of digital media and the "culturalist" or critical theoretical side. Bolter asserted that critical theory is not designed to help make things; that it is not in effect "productive" in the sense of resulting in a product. Rather it is there to make an intervention in the form of critique. On this point there was no dissent from Bogost, who likewise indicated that, "theory's purpose is to change perspective, not create output." [3] And they were absolutely correct in this from the standpoint of measurable outcomes—the critique critical studies offers could be characterized as a drag on productivity, a kind of noise that disrupts the flow of creative efficiency. This is because its concerns are not with production, but with honing a set of critical tools that vigorously assess the products of a given society for their underlying meanings and ramifications. In its questioning and self-reflection, it can be seen to slow immediate results.

Bogost and Bolter debated how the procedural and critical culturalist aspects might better dovetail, a question that hounds combined theory-practice programs. Bogost suggested that the two elements mesh well in digital art production; others suggested this is demonstrated in design, or that it may be the role of scholarship to integrate the two. This seems to configure the coming together of theory and practice as the purview of artists and other 'creative' types, to relegate it to the aesthetic or the academic, as opposed to centralizing its importance for the procedural.

What is this apprehensiveness around theory? For me this question, with its attendant procedural / culturalist tension are connected to a larger contemporary crisis of higher education, particularly the conflict between the classical understanding of the university as cultivating intellectual acuity, versus the more neoliberal iteration of the university as training ground for capitalist enterprise. Writing on this crisis of academia, Gregory Jay characterized it as such:

[a] fundamental tension arises between the academic mission of preparing students to be critical citizens and neoliberalism's demand that they subordinate themselves to the dictates of the market. Obviously, neoliberalism has no need or desire for academic research that questions its operation, as such criticism creates 'inefficiency' in the market. [4]

Even the tools themselves beg not to be analyzed. The clean, abstract shapes of laptops and mobile devices, inscrutable and minimalist, disguise their histories and origins. This is often only ruptured by accident or technical glitch, for example in the famous so-called "iPhone girl" photos snapped of a young Asian factory-line worker that went out on the new device, discovered later to the delight of its owner. [5] That amusement is only possible because of the seemingly insurmountable distance between the phone's assembler and owner, which those images instantly broached. This factory image again masks another representation: that of the waste management and reclamation issues that plague mass production. On the back end of the technological cycle, is the ecological crisis of e-waste; armies of unfortunates must contend with the tidal wave of obsolescent technology, and run the gauntlet between spaces of production and capitalist excretion that mar the environment.

Indeed, there are many ways in which the theoretical contemplation seems not to mesh well with production. Setting these aside, I would argue that the theory's presence in new media scholarship chafes at sensitivities that arise out of an overarching shortcoming in the area: we lack an ethos. That is to say, we may refer to ethics-based theory in our products, but that is very different from having an ethical grounding that guides, provides purpose and articulates a code for the movement. Theory provides the tools for ethical debate and self-critical reflection, and surely serves to articulate concerns that have ethical ramifications. Yet is often seen as an external punitive force, and hence side-stepped. However, rejecting the influence of theory as secondary to production does not displace the central importance of ethics. Ethics in the disciplinary methodologies of new media should and do precede theorization; ethics should act as agreed-upon fair and honest practices in advance of whatever our diverse disciplinary outcomes may be.

Technological development is ideologically configured as ultimately good, necessary and fundamental for progress; that the moral obligation to pursue innovation outweighs the ensuing sacrifice. It carries with it the promise of social betterment through technology, including but not limited to true democratic inclusion, a global web of consciousness and the outstripping of bodily limitations such as mortality. [6] However, there remains the matter of bodies, and how advanced technology imposes itself upon subjects in the world. An array of activist scholars have challenged the ethical neutrality in technology discourses and their visual cultures, including among others: Lisa Nakamura, María Fernández, Thuy Linh Tu, Wendy Hui Kyong Chun, Jennifer Gonzalez and Coco Fusco. "For all the celebration of mobility and fluidity," Fusco has written, "digital technology organizes a world economic order that thrives on a global labor pool of poor non-white people – for whom 'access' to many critical signifying practices – legal, symbolic, and electronic – is diminished and even denied." [7] Fusco along with many others argue for a more equitable set of relations between a global North and South, calling into question the duress of technological production on the bodies of disenfranchised laborers. These scholars are undertaking important work that deconstructs the present-day continuation of imperialist expansion and the rhetoric of technology as progress. They importantly tackle the issues of post-colonialism, hybridity, mobility, migration and Diaspora as they intersect with new media.

My inquiry here, however, is not a cultural studies-based critique of technology. Rather, in a larger sense we have to ask ourselves as members of a common set of interests: what is important about what we do? What is so consequential that intellectuals from other fields would look to our theorists to identify key ethical concerns related to technology in the world and, more importantly, derive useful reasoning that can have impactful resonance outside the hermeneutic specialty of new media? What is it that new media studies produces that is different from what Silicon Valley does? How can our field of collective interests have global relevance – or, lacking core values – even sustain itself? What do we hope to achieve if we do not have ethics?

Consider one lynchpin of internal ethical conflict at play in new media: the imperative to constantly innovate drives technology forward – and this drive is embodied both by those who undertake the challenge of developing new technologies, as well as those who intercede, such as hackers and other interventionists. Alexander Galloway describes this imperative as a part of a larger discussion on the political dimensions of network architecture. "Hackers," Galloway explains, "don't care about rules, feelings, or opinions. They care about what is true and what is possible. And in the logical world of computers, if it is possible then it is real. *Can* you break into a computer, not *should* you or is it *right* to...In fact, possibility often erases the unethical in the mind of the hacker." [8] Galloway refers to hackers and their relationship to code and specifically protocols, but the paradigm of "possibility eras[ing] the unethical" is quite

apropos to other areas of technological development, where the pursuit of innovation demarks a frontier to be discovered as an inevitable form of progress. Technological innovation races toward the promise of a horizon where the better, modern, efficient and more functional purportedly hold libratory potential for culture. As a result, technological industry seems to function largely autonomously from a self-critical apparatus beyond that demanded by capitalism, to guide its aims. Hackers react to institutional systems, certainly tangle with the machine, and are ideologically configured as having an antagonistic relationship with capitalism. But as Galloway points out, this is separate from having an ethical framework to guide them. And in the end, their efforts may ultimately and inadvertently contribute to the strengthening of the controlling logics of protocols, by pointing out the loopholes and backdoors that are eventually sealed. Certainly, Galloway's perspective generalizes; still, it illustrates its point well. It is this question of the ethical (as opposed to merely the possible) that requires a critical foundation, one built from sound theoretical building blocks.

I have here characterized a series of challenges, each nested inside the next: new media exists within a context of globalization, while its theorization seems not to acknowledge major ethical concerns of that context. Meanwhile new media studies is currently driven by its procedural side, while its diminished critical culturalist side seems to contradict the logic of production. However, without critical examination and contextualization, much of what new media does is indiscernible from research and development – a compromised position in the face of the tech industry and its resources. When subject to the accelerated expectations of technological innovation, such production can only temporarily impress audiences, before facing the certain doom of obsolescence. Armed with an ethics and a set of critical tools with which to self-evaluate, new media scholars and producers social actors with agency to affect global outcomes, and whose cultural context is inextricable from their innovation.

One need make no argument about the connectedness between cultural context and the tools that form the object of study for new media scholarship. Noted sociologist and scholar of globalization Saskia Sassen, in example, contests the dominant understanding of the relationship between digital and non-digital spaces. Sassen argues that the dematerialization associated with digital media is largely myth, and in fact the goings on of the datasphere are deeply bound to the material world.

The digital is imbedded in the larger societal, cultural, subjective, economic, and imaginary structurations of lived experience and the systems within which we exist and operate. At the same time, through this embeddedness, the digital can act back on the social so that its specific capabilities can engender new concepts of the social and of the possible. [9]

The feedback loops that she describes between the digital, the non-digital, the social and the possible evidences an interplay that is mutually influential; it potentially opens up new and fertile territories for conceptualizing our sphere of activity not as hermetic but rather engaged with context and subjectivity.

This is one of innumerable possible perspectives, the lenses for which already exist in the array of disciplinary approaches associated with critical studies such as sociology, philosophy, political science and media studies. Seyla Benhabib, a venerated political theorist, utilizes liberal democratic philosophy to reason through the ethical challenges heightened by globalization. Benhabib emphasizes moving from the rights of citizens as defined by national identities and borders, to universal human rights, which acknowledges the increasingly porous nature of borders as a result of global flows of capital, products and bodies. [10] Manuel Castells, arguably one of the most important living sociologists studying the impacts of globalization and advanced communications technologies, has recently published *Communication Power*, which ambitiously undertakes to characterize sweeping impacts of both online social media and

traditional mass media—what he calls "mass self-communication" and its reshaping of global power. [11] Clearly discourse of advanced technology is inextricable from ethical conversation. Technology implements ethics, whether or not its makers self-consciously select or even recognize their ethical positioning. In fact, I would go so far as to say that forms of technology are ethical philosophy in practice. Hence, it is imperative to bring sophisticated language and critical frameworks that enable ethical conversation to take place, within discussions of new media.

As a relatively young area of interest, new media studies need only look to another recent disciplinary struggle, namely that between art history and visual studies, for a cautionary and instructive example. Mieke Bal, a noted cultural critic and theorist, has written of art history and its notorious lack of "methodological self-reflection," which led to a profound crisis around its object of study, and the subsequent formation of alternative approaches to visual and material culture. [12] The emergent scholarly discipline, visual culture studies, promoted analysis that brought rigorous self-criticality to the table. This radically reconfigured the objective of study not in terms of a pedigreed object, but always with a skeptical relationship to the object in its various webs of relation. Meaning, then, does not issue only from the form in itself but also context—and the analytical tools possess a kind of 'self-sharpening' feature. In time, the academy has seen the melding of art history with visual studies; many departments now bear both names and support both approaches as a means of ensuring the contemporary relevance of art history, while grounding visual culture in the object to some degree.

How can we, by developing a problematized relationship to our own material, continue to evolve what we do as new media experts? Now that we are finally moving beyond defining what new media is or isn't we are free to move on to possible tasks such as probing technological essentialism in its many forms, unveiling the workings and political urgencies of advanced technology in context, and advancing a commitment to new internationalism as constitutive of technological experience.

I would like to return once more to the conflicts of the "procedural" versus the "critical cultural"—a dualism that falsely divides the intellectual labor around technology, and that needles the anxieties of both theorists and technologists, particularly those occupying the academy. Theorists are anxious that they aren't understood to be 'making' anything, that they aren't productive, per se, and more likely slow the process of production. Further, in the cases where theorists are not also 'makers,' their contribution may be diminished as navel-gazing and interloping into a conversation occurring between producers. However, contrary to the idea that critical theory produces nothing, the intellectual discernment and criticality developed from training in critical methods is measurable as well, however along much longer timeframes and long-tail effects. The rigor of the resistance criticality provides refines the procedural dimension, but also introduces theoretical and ethical self-regulation to its operations. One senses, in kind, the angst of technological producers who are constantly anxious that they don't make anything important or lasting. Innovation is always overtaken by the subsequent innovation, seemingly without end. The solution to this quandary lies in the development and valuing of a theoretical feedback loop regulated by an ethical framework that takes into account the context and players through which technological progress is made possible, and through which it enacts itself. This should be a rigorous, systemic part of the scholarship that influences the outcomes of production. The digital media we use are not neutral tools, but enact social, ethical and moral worldviews. Theorists and producers needn't worry: the work we do is relevant; but before we study digital materiality, presentation, aesthetics or evolution, before we theorize the algorithmic or the informational, we need core ethics. For a disciplinary sense of self-assuredness that can enable digital media theory and production to do good work in intellectual culture and in the world, it requires a strong ethical philosophy.

HUGGABLE NATURE WORKSHOP

Hye Yeon Nam

Huggable Nature is a public workshop in which participants create wearable interfaces using simple arts and crafts materials to express playful affection towards nature. Specifically, participants design and construct tangible interfaces, which enable them to leave voice messages that play back when they hug trees wrapped with fabric interfaces.

Motivation and Background

MOTIVATION

In the past, when various workshops entailing mechanical electronic parts, including software and hardware, were introduced, organizers often encountered difficulties. For example, at times, their participants felt that they needed to have an equivalent knowledge of computer science or electronic engineering prior to attending the workshop. [6] Simple micro-controllers such as Arduino and Lilypad facilitate participants' engagement with interaction design. [7] However, with such platforms, users still need to have a basic knowledge of programming.

The *Huggable Nature* workshop is intended to provide participants with playful interactions with nature. Because *Huggable Nature* entails the use of simple arts and crafts, with which most participants can use easily and quickly to create interfaces, it is designed for general audience. *Huggable Nature* is a forum for providing playful experiences and for examining participants interacting with nature rather than producing refined results.

BACKGROUND

Do-it-yourself (DIY) practices have been explored in several fields such as sustainable design, fine arts, politics, and health. [1] The general definition of DIY in design and arts is making a product one-self. Broadly, when people create, fix, reuse, and assemble materials, we call it DIY. Popular culture has reflected these movements in TV series and magazines. However, recently, the meaning of DIY has often been used for sharing information, following printed instructions, and collaborating actively. It includes not only the final outputs but also the experience of sharing knowledge and techniques with others. [7] Through DIY, activities become more like playful leisure. People become more engaged and creative when they are enjoying themselves. Such an enjoyable environment is embodied in *Huggable Nature*.

- Popular Culture

The British television series *Barry Bucknell's Do It Yourself* and *Bucknell's House* in the 1950s and 1960s and American action adventure television episodes such as *MacGyver* (1985) and *The A-Team* (1983-1987) played an important role in the popularization of DIY activities. [6] Fan magazines (fanzines) are

also DIY activities, but ones that actively build underground communication channels related to music and sports. [10] A number of fanzines were generated during the first wave of the punk movement in the United Kingdom (1976-1979). Psychiatrist Frederic Wertham has described fanzines as “a special form of communication” in *The World of Fanzines* (1997), and the American writer and academic Stephen Duncombe has characterized fanzines as small publications in which producers create their own unique culture. [2] As independent, self-published publications, fanzines build identities of freedom and resistance in their contents and graphics influenced by the self-empowerment aspect of DIY activities.

- Do-It-Yourself practices

Traditionally, *leisure* has meant the opposite of *labor*. Leisure is regulated by the individuals themselves, whereas labor is structured by other supervisors. British neo-Marxist scholar Edward P. Thompson describes how people’s understanding of leisure time changed as a result of industrialization in the late eighteenth-century. He states that “In all these ways - by the division of labor; the supervision of labor; fines; bells and clocks; money incentives; preachings and schoolings; the suppression of fairs and sports - new labor habits were formed, and a new time discipline established (p.394).” [9] American author Steve Gelber points to the value of DIY activities as hobbies or creative endeavors, noting that “the ideology of the workplace infiltrated the home in the form of productive leisure (p.2).” [4] In this context, he claims that labor could be viewed as leisure. Creative DIY activities bring all the qualities of leisure to labor. Participants in *Huggable Nature* do creative activities individually, share opinions with each other and design arts and crafts to express their affection towards nature. In these activities, they are self-motivated; they do not experience it as labor, but as leisure.

- Playful Interaction

Interaction designer Bill Gaver states in his essay “Designing for Homo Ludens” that “play is not just mindless entertainment, but an essential way of engaging with and learning about our world and ourselves.” [3] He emphasizes the importance and the power of engaging in and learning from play that accompanies intrigue and delight at all ages. For example, in one of the *Huggable Nature* workshops in an Istanbul high school, a senior high school student designed interactive lingerie for hugging trees, thoroughly enjoying the process of creative design. Sometimes she shouted or giggled with her friends while she created and interacted with her devices. In another *Huggable Nature* workshop in the Atlanta Mini Maker Fair, a five-year old boy participated. As he was too young to sew fabrics, he painted conductive inks onto pre-cut wearable devices. After he finished his paintings and left voice messages on the trees, he was excited that his voice messages played from the trees. He commented, “The tree is talking to me.” He seemed to treat the trees as conscious beings. Because the *Huggable Nature* workshops are based on creative ideas and physical activities applicable with all ages or interests, participants are excited about expressing themselves, connecting with nature, and interacting with one another.

Workshop Principles

The *Huggable Nature* workshop is designed to accommodate participants with different abilities and skill levels. The beginning of the workshop leaves time for the exchange of opinions among participants. Then, participants rapidly and easily create playful devices that interact with trees using arts and crafts within a limited time frame. The workshop follows two general principles:

- Openness and collective ideas

People sometimes take nature for granted. In the *Huggable Nature* workshop, participants look for ways to appreciate nature. For example, participants often say that they have never communicated their affection and appreciation to trees before *Huggable Nature*. Also, when they discuss their experience with nature in the workshop, they exchange their ideas and improve their designs. With the success of open software such as *Processing* or *Openframeworks* and web participatory models such as Wikipedia or YouTube in Web 2.0, [8] we can see the evolution of “shareability” and the power of openness in other media. The concept of shareability is similar to Henry Jenkins’ “collective intelligence” or the ability to pool knowledge and compare notes with others toward a common goal. [5] The *Huggable Nature* workshop reflects the concepts of shareability and collective intelligence through active discussion and collaboration, both of which create synergy. As the workshop progresses, unrefined ideas are articulated and implemented into concrete outcomes. Since the *Huggable Nature* workshop is held outside in a park or community garden, more people participate in discussing ideas and creating wearable devices to interact with nature.

- Simple processes and immediate feedback

The *Huggable Nature* workshop focuses on enjoyable and creative designs that are interactive with nature. Simple crafts and DIY practices allow participants to concentrate on their prototypes and minimize the fear of and the need to learn extra technologies. When participants see immediate results, they maintain their interest. In the workshop, they use conductive threads, yarns, fabric or ink to create wearable devices. While touching and hugging trees with their own devices, they close electronic circuits. When the circuits close, participants immediately hear their own or previous participants’ recorded voice.

Workshop Structure

The *Huggable Nature* workshop has been developed over the past two years and presented in three different countries. *Huggable Nature* consists of four steps: set-up, discussion, design, and interaction.

SET-UP

Before the workshop, organizers wrap fabric interfaces around trees. The wrapped felt fabric contains micro-controllers, sound recorders, and speakers. Some interfaces are decorated with words such as “I Love you” or “Hug Me” or with figures of smiling or whispering human faces (Fig 1).

DISCUSSION

In the beginning of the workshop, participants talk about their interactions with nature in their daily life and discuss how they make their surrounding environment happier.

DESIGN

Participants create devices crafted from art materials that they can wear to touch or hug the fabric on the trees while expressing their affection. Some make bracelets or gloves, and others create t-shirts or masks.

INTERACTION

The participants leave voice messages on a recorder attached to the fabric. Then they put on their own designs to touch or hug trees to listen to their own or other participants' messages.

Workshop Results

The *Huggable Nature* workshop has been held in four places: Washington Square Park in New York City on October 9, 2010, as part of the Conflux Festival, the Sao Paulo Cultural Center in Brazil on July 19 and 20, 2011 as part of FILE (Electronic Language International) festival, at the Georgia Institute of Technology in Atlanta on September 10, 2011, as part of the Atlanta Mini Maker Fair, and at an Istanbul high school in Turkey on September 12, 2011 as part of the ISEA (International Symposium on Electronic Art) conference. The first and the third workshops lasted about three to five hours and were attended by about 30 people, including families and local community members, all of whom spontaneously participated in the workshop. The second and the fourth workshop were spread over five hours in one or two days and were attended by around 10 people. All the participants were pre-registered. The following section contains a selection of workshop results:

INTERACTIVE BRA

In the Istanbul workshop, a senior high school student designed an interactive bra for hugging trees. It had two fabric pieces connected with two strings. One was tied in the middle of the back and the other tied behind the neck like a swimsuit. She designed heart shaped conductive fabric and attached it to the printed fabric. After she finished her interactive bra, she recorded her voice messages to the trees. Then she put on her conductive bra. When she hugged the tree, the conductive fabric closed the circuit in the interfaces wrapped in the trees to play her voice messages.

INTERACTIVE GLOVES AND MITTENS

Participants created various gloves and mittens in the workshop since most participants touch the trees with their hands. Some made mittens to avoid sewing a space for each fingers, while some fashion major participants decorated their gloves with letters from "LOVE" or added complicated designs or fasteners (Fig 2).

INTERACTIVE BRACELETS

When participants made interactive bracelets, they needed only rectangle shaped fabric and Velcro tape. Since this is the easiest way to contact trees, young children who are too young to sew fabric as well as adults who do not want to sew paint conductive inks on the pre-cut bracelets (Fig 3).

After they made their designs, they recorded messages, including "Hello trees, I love you and I love hugs," or "You are the earth and so am I." Then, they put on their own designs. When they hugged or touched the trees with their designs, they heard their recorded voice. Some of them became excited

and shouted. Other participants giggled. Many of them urged their friends to participate. After their interactions, the participants gave feedback about their experience. Most said they felt closer to the trees or at least had a positive experience.

Conclusion

The goal of *Huggable Nature* is to have participants reflect on their feelings about nature. By including easy to use arts and crafts materials and techniques, participants can comfortably get involved in the workshop. Whereas many other similar workshops focus on groups of people with similar abilities, the *Huggable Nature* workshop is open to all individuals regardless of their experience, age, income, or technical skill. Currently, participants can only interact with trees in limited interactions. In future workshops, we will add other objects in nature and other modes of interaction.

Acknowledgments

This work was supported in part by the National Science Foundation grants ISE-0741685 and from the Georgia Institute of Technology Public Design Workshop (<http://publicdesignworkshop.net/>) and the Next Generation Design Leaders Program, which is funded by the Korean Ministry of Knowledge and Economy (MKE) and administered by the Korea Institute of Design Promotion (KIDP).

AN AMORPHOUS IMAGE PROCESS

Kevin Sarmiento Navarro

This creative and constructive process is based on a different approach toward thinking, in admitting if the image to build expects to determine what reality is and what amorphous reality is, or to produce a series of "images" with a correlation into an amorphous concept.

Fig 1. The Saltropomorphous

Fig 2. Night morphous

Fig 3. Image Transformophous

“The Saltropomorphous” (The jump of an amorphous landscape), is the imaginative idea of a sub real abstraction of a linear moment of form, colour and volume; Beginning from the concept of an isolated landscape inside of a real or imaginary boundary of “amorphous space” that because of being in the light, generate a shadow or “mirror image” with opposite properties. Two ways to allow each an intermediate step to be an equilibrium state, and produce in a sense the “jump” of the amorphous body into its own unchangeable notions of time and space(s).

AN AMORPHOUS IMAGE PROCESS

This creative and constructive process is based on a different approach toward thinking, in admitting if the image to build expects to determine what reality is and what amorphous reality is, or to produce a series of “images” with a correlation into an amorphous concept. The possibilities are endless, because amorphous thinking in visual terms is an inextricably bound up with sensation and perception. In many ways, how we think is how we see and vice versa. The same mechanisms operated on both the perceptual and the intellectual level, so, these inevitably terms like concept, judgement and conclusion, have to be applied to the work of senses on the use of a method for an amorphous image creation.

Process art attitude may be direct as far as possible toward the perception of “image as such” and closer as possible toward a perception of “amorphous”, to visualize a conception of boundary and form, a brewing scenario for an intuitive vision of an amorphous space, a lapse of time of constant flux where energy and information coming into existence, light and shadow, harmony, a form of animism, the unpredictable on the observer visual sense, the emptiness of absolute identity, an 'inherent existence' – perceived and thought to exist 'from their own side' exactly as it appear.

In the process of creating, the image environment has the constructive idea of “amorphous space”, to create the capacity of finding different approaches, generating themes around space and time, thus springing the changes where the image shape is subdued by the external elements that make it.

Amorphous *thinking* in the form of amorphous images, will transform those amorphous spaces resembling a boundary that never exists inside of it; observer only will see a bit of an image that cause his senses to produce images that make visualize amorphous image shapes.

If the process undergoes a cycle, whether it becomes a larger space, or smaller, then it will have the same amount of image space each time it returns to a particular point. Nevertheless, the open flow of image event is another transfer mechanism, a quantity of image which is independent of any particular process.

For an amorphous image with a few space, the variations in the image parameters become larger than the image processed, and the assumptions of an image process is meaningless. It is an expression of the fact that over time differences in an image process, its place, and results tend to even out an image process which is isolated from the observer.

Therefore, An Amorphous Image Process has its own laws of construction, with problems representing the process of amorphous thinking in visual terms. Though, instead of being formulated the medium of image language, is embodied in visual terms the medium image and process form elaborated, a visual reasoning or visual language, an inquiry based on the constructive and creative process, the cognitive knowledge, instinct and intuition, to encourage and to explore the speculative and the experimental nature into the notions of image place, image space and image event.

AMORPHOUS IMAGE SPACE-RELATED EFFECT

When two amorphous images are in visual contact with each other, there will be a shapely between these unless or until this are in equilibrium. It is not a good idea to create an amorphous image space without any mirror image support. This is a conservation of an image connection. It may refer to the two ways that a closed space transferring to and from its surroundings, by the process of intuiting (or constructing) an amorphous space. The real or imaginary boundary in an amorphous space of an image shape is determined by the image event of these two processes. The amount of an image place in a constant process cannot be greater than the space showed.

Seeing moving space as an image event, if a space moves in a forward direction and one, as a moving image on space, observer will never see the image reform. Images are “jumping” all the time, but never reforming. Therefore, the constant of any unique image place stage is zero. If an amorphous image process happens to have half-image face about quickly, there are two images stages, related by an image-reversal-symmetry, so the dimensionless image constant becomes the record of two images. That is the image for the whole space on any amorphous image. Basically, an amorphous image can not reach an absolute zero space.

Accordingly, images with large associated forms take long time to visualize. For an image of any complexity some of the realization in the amorphous image process could be a two-view image system. The image *viewed* through a first space, to excess image elimination, generating a mirror image which is

stored in a shape. The second process sorts the mirror image, which is then shaped in a quicker image to be visualized.

This alternative approach is to use a concise image form together with indirection spaces. This will reduce shape requirements and performance time. It is convenient to re-use a constant image space form used as in excess of space elimination. The previous space is reduce and convenient. There are two new images and deleting the excess of shape will keep a constant image space form programmed associate for a faster generated image.

In the development of an amorphous image process there is a similarity to the development of feeling from reason, of emotion from language. Emotion = image; language = process. Image shape comes about as the result in return action of two or more intellectual emotions; an amorphous image process occurs from the image impinged of two or more image processes.

Consequently, an amorphous image space represent the possibility of expressing a new image world, because it offer a brewing scenario of an intuitive vision, and during the lapse of the image process, it transform artistic intuitions without having to change images, only transforming it for the benefit of harmony.

Meanwhile most people cannot discover what matter about an amorphous image process and its space-related effect; I can consider what matter about it, as an original and authentic question for a research and experimentation on images transformation.

IMAGE TRANSFORMORPHOUS

An amorphous image process as the begins of an endless line of continuous transformation of an image place, a mirror image space for everyone image event, continuing without stopping, or being interrupted in space or time

DIGITAL TECHNOLOGY, SOCIAL MEDIA AND EMERGING TRENDS IN FILM PRODUCTION METHODOLOGIES

JODI NELSON

I am interested primarily in how the new paradigm shifts in digital technology and the democratization of the filmmaking process allow filmmakers to connect to an 'expert' global niche audience with more immediacy through the internet, engaging virtual communities, crowd funding and fan building initiatives and a variety of social media landscapes.

DIGITAL TECHNOLOGY, SOCIAL MEDIA AND EMERGING TRENDS IN FILM PRODUCTION METHODOLOGIES

With the new paradigm shifts in the film industry, cheap digital technology and the democratization of the filmmaking process, filmmakers now can connect to an 'expert' global, niche audience with more immediacy through the internet; engaging virtual communities, utilizing crowd funding support and fan-building initiatives through a variety of social media landscapes.

NEW PRACTICE METHODOLOGIES

My own work has revolved around two kinds of practice; the first, a traditional methodology invented by the Hollywood studios, which, from a small independent filmmaker stand point proved futile at best. With little to no resources to pull off a production like the big studios do, with their huge studio budgets, political backing, global media support and accounting practices, today it seems a waste to pursue an independent film production in this manner. The second practice is participatory filmmaking. This method enables others to articulate their experiences through my artistic vision via cheap digital technology and social media. It is through this process, they have just as much (or little) control as possible as the filmmaker. But, why you ask would filmmakers want that?

"What defines the documentary genre is also at the root of its limitations...here, I shall call for a different perspective on documentary form: not with a view to discussing what documentary is, but to make some suggestions of what it could be." (Knudsen, p. 109)

In creating the participatory film project and case study entitled: *Single Girl in a Virtual World: What Does a 21st Century Feminist Look Like* my practice aims to engage multiple social media communities such as; Facebook, Twitter, MySpace, Wordpress, YouTube, Kickstarter and IndieGoGo and ask people to participate in the film project itself with a sense of creative input. During the production, I have asked the communities to read the film site's blog, watch podcasts, comment on news feeds and follow me on Twitter. These efforts are the practicalities necessary for audiences to participate in the film project itself – either creatively, financially or both.

The project's content has begun to emerge and appears in its raw shape as a video diary of sorts, with participants weighing in on the topic of the week, freely giving their insights, thoughts and feedback through the multiple social networks—either in video, textural or both. For the filmmaker, this serves as a rich valley of resources that can be integrated in the film's narrative. However, when attempting to construct a narrative thread by gathering content in this way, it brings up many potential problems. "Recording a video diary, if you don't want it to become public, is a risk; perhaps more so than a written diary, because the medium of video implies a mass audience." (Rothwell, p. 154)

One of the exciting things about these new possibilities for filmmakers and audiences alike, despite the potential ethical pitfalls, is the creative flow of information, access to resources and sharing of content. Independent filmmakers who are limited on budget, time and production technologies can gain a tremendous amount of quality production value by sourcing content in this way.

Whichever way they came into the community, the goal is to keep them there, involve them in the production efforts and keep them just as excited as you are about the project. And to do that, there must be a transparency between the creator and the fan-base participating in the project itself. This covers a multitude of scenarios such as; copyright issues, ethical boundaries, life-rights, video-audio rights and original content ownership. By simply asking for their permission seems to be fair enough for their participation. "Key to the success of that relationship is that it demands a responsibility for the consequences of the filmmaking that go beyond the film itself." (Rothwell, p. 155)

When I started this case study, I had an overall fear of intellectual property thievery; which stemmed from my traditional, Hollywood studio practice experience. "Rather than oppose this "illegal activity," we welcomed the pirating and began distribution directly to the pirates at production cost value." (Blagrove, Jr., p. 176) Delightfully, once I began my practice in this participatory way, I could begin to see it actually had many benefits of being 'stolen' and shared virally. The more I blogged and podcasted calls-to-action the more activity my social networks would see, more members would sign up for my news feed, follow me on Twitter, 'Like' me on the *Facebook* page, and read my *Wordpress* blog. Then of course, the whole idea of this process was once they were fans within my social networks, they would participate and share content I could then use freely in my film.

VIRTUAL AUDIENCES

"The on-going conversation with your audience can be a source of inspiration, motivation and ideas. It's this powerful new link with the audience that the old power players don't understand." (Kirsner, p.4) I can no longer imagine going back to a traditional filmmaking practice hoping to make a modest living, or even attempt to have a sustainable career by playing by the old rules of the studio production and delivery system. The windows of financing and distribution are just too complex, too expensive and too long of a cycle to have any hope of quick returns on investments or to gain access to huge marketing budgets for global exposure of film product.

"By empowering ordinary people to speak as experts, they question the basic assumption of dominant ideology, that only those already in power, those who have a stake in defending the status quo, are entitled to speak as if they know something" (Juhasz, p.304). It is with this notion that is measuring how social media, digital technology, alternative production methodologies and various new delivery strategies

are providing information on the impact of the film's message and its creative process. Does this mean the film is suitable for a theatrical release?

My practice is showing that audience participation does, in fact, impact both the audience and the filmmaker inherently by creating art in this way. Instead of outsourcing functionalities to other resources in a traditional sense, I had to become an all-encompassing expert. But, one now asks the question - who is in control? Who is the 'auteur' with the vision? What happens if the film's narrative thread goes off-track? Who are the performers and what ethical considerations are at stake?

How can I draw an audience into the reality of the situations being dramatized, "to *authenticate the fictionalization*?" ...what are we to make of films where real people apparently 'play themselves' (or variations on themselves), or hybrids where a combination of actors and non-actors improvise in a documentary-like scenario?" (Ward, pg. 192) It is the originator's role to ensure that the participatory environment also abides by the community rules of transparency, honesty and attributes of authentic form. "Notions of performance in documentary are therefore potentially controversial – accusations of people 'not being themselves' or 'playacting' are rife, and are deemed to be a central problematic for a film's documentary status or credentials." (Ward, p. 192) Otherwise, not seeing these participants in person; looking them in the eye – how is the filmmaker to know what is factual or fictitious?

A greater embrace of innovation and experimentation in this method is needed in leveraging these projects with the ability to fail without showing loss of value. Technological knowledge and new creative approaches to build communities and better business models that filmmakers and artists alike are needed. It is possible to achieve a quality film production with inherent.

By engaging in filmmaking practices in these fundamental ways, a shift of power away from the larger powers of the studios, and back into the hands of the creative filmmakers and their loyal fans should be embraced, not feared. "The question for makers, consumers and scholars of moving images are what distinguishes documentary online from documentary made for other channels, and whether the internet has any distinct, useful or unique characteristics that offer documentary anything more than just another means of distribution." (Birchall, p. 279) A process of creative flow, execution and community outreach is a necessary part of this practice and to maintain a sense of shared community.

TECHNOLOGICAL SHIFT

A profound new shift in mindset was needed to set off on a new course of practice; even though outcomes are uncertain. "First, in organizing geographically diverse individuals around a common interest in watching or making documentaries, there are new forms of community; second, new means of creation and distribution...to seek to change people's minds or reinforce a viewpoint; third, we have increased access to 'dirty reality' in the form of footage of current events and violent conflict; and fourth, video diaries and other moving images give us an increased range of intimate access to the lives of other people." (Birchall, pg. 179) Differences in workflow patterns, a means of gathering content, and a creative approach within high production value considerations, compromises and technical limitations stretch limits on what is possible.

Thousands of entries, news feed comments, tweets, sharing of videos and user-generated content (UGC) from YouTube and other rich video sites by community members fill the coffers of content. Skype interviews became a relevant resource of production activity for capturing remote interviews, even though the media is still not high value. During this process, I discovered because I was developing a rich social network, people I knew in my personal social circles; friends, family, co-workers, business associates, etc. suddenly became keenly aware of the project I was making and were eager, or at least willing when pressed, to participate in the project.

User generated content (UGC) has been the most pervasive amount of content, shared and streamed by my community members so others can comment, share and watch within the framework of the film's websites. "By contrast, the easy availability of material to work with online is matched by the ease of remixing and redistributing." (Birchall, p. 280) This aids the independent filmmaker who need open-source, archival clips in order to create a film narrative. There are ethical and intellectual rights considerations, however that must be mentioned.

It is also important to note, because technology is cheap, social media pervasive and artistic democracy entering the creative fold, doesn't mean the value of the art or the filmmaker behind its creation should be valued any less. "People made information about themselves available on the internet in such a way that theoretically anyone could see it, but in practice few did." (Birchall, p. 281) The reality of the new entrepreneurial filmmaker is not only making just a film project, but rather building a community of like-minded people who want to support a film project and future projects – in essence building a sustainable brand. This takes an inordinate amount of time, effort, management and technical troubleshooting. Not to mention, technological requirements, necessary to connect all of these networks in a functional and significant way - once they are functional and put in motion, should self-perpetuate. This is an ongoing resource of time and labor that must be considered.

The benefits in making art in this way far exceed the amount of time and effort it takes to build an online brand and identity. Other filmmakers too, are building sites with the intention of creating a sustainable business model, as well as attracting a built-in fan base that can't be bought with traditional advertising and press campaigns by the larger studios. The case study of *Four-Eyed Monsters* by Arin Crumley was a forerunner for this social media movement. Films are now being made everywhere and there are audiences out there who are looking for them. Audiences, however, are fickle, but entrepreneurial filmmakers have a distinct advantage over the big studios by creating art that is meaningful and creatively autonomous, while building a loyal fan base, which will enable the artist to self-sustain.

PARTICIPATION

Does the 'audience' participating in the early stages of a creation raise expectations for the audience? What about for the filmmaker? Does it impact the artist's methodology of creation itself?

Participation between audience and filmmaker enables each to develop a relationship that goes deeper than merely one from a consumer or isolated artist's point of view. It becomes a two-way process; although being auteur and the creator of the project, driving the subject matter, its pacing and narrative criteria, provided an overall control and direction for the project. It is important to note, that

its subject or method itself wasn't diminished in value, nor did it have the perception of being an amateur product. In fact, it's been the opposite, which emphasized stronger value for both the filmmaker and the project being created with the audience. The process has allowed a more authentic, accessible and transparent relationship to develop amongst the community, which makes the film's subject, and experience, more tangible. Having the film aimed specifically towards a key, niche audience, seems to make them keen to be involved and stay invested for future projects. It is the script or narrative and production value which must be the best possible so there is a perception of professionalism throughout the production.

The community does, in fact, communicate amongst themselves and will certainly 'police' any activity that does not acquiesce within the group. This 'policing' by the community assures transparency, trust, authenticity and protection against spam and unwanted advantages a filmmaker or other community member may seek to squeeze information and/or money out of its community for personal gain. "The immediacy of new online forms should not be mistaken for a lack of mediation...authenticity is highly prized by audiences." (Birchall p. 282-283)

There are certain sacrifices that must be made outside of the normal filmmaking agenda; such as engagement in crowd sourcing campaigns, new technological learning curves and social media training, traditionally hired out (i.e. media partners, technology programmers, sales/fulfilment houses, marketing firms) must be learned. There are many perceived benefits, as well as challenges in this new era of digital technology and social marketing tools that are advantageous for both the filmmaker and their audiences.

Measurable changes in production practices must also be adhered to by utilizing these online tools and cheaper production technology. How does this change the storytelling process?

Technological considerations must be made for the lack of financing and a large crew. The entrepreneurial filmmaker is now essentially a 'one person crew' where every single shot, direction, post-production/editing, writing, producing, marketing and digital online development and management can be achieved with the sole artist. Aesthetic compromises are also at stake. However, it is worth noting that with small cinema, mobile and online video distribution choices that are growing every day, there are many outlets of distribution that do not require a 35mm or HD production aesthetic to tell a story. Ultimately, the script is still at the heart of every film – it is only the methodology and system of delivery that has changed. "The film business remains a single product industry. The product may be available on many different platforms, but it is still the same thing." (Hope, 2010)

With the attraction of crowd funding sites such as, Kickstarter and IndieGogo, financial resources are now available for filmmakers, who don't have access to rich uncles, mix with the Hollywood investor crowd, or can fund their projects across a mass of credit cards. "Expectations have changed considerably, probably completely. Buyers and audiences behaviors are different, those that still remain that is. Products are valued at different levels. We live in a new world. Our strategies must change with it." (Hope, 2010) The production and fundraising of a film in this style is beginning to produce a more valuable, sustainable, niche-market product and is changing the traditional market structure of distribution and delivery for independent filmmakers outside of the Hollywood system. It is also providing a platform for artists in countries without the support of film communities, government subsidies or fundraising activities. This enables a global access to films and stories that might otherwise never be told. "On the face of it, *Kickstarter* is pretty harmless, and I think the founder's intentions are good. It's great that people can raise money for cool things from the crowd. It's hard to raise money, especially for the arts, and

there have always been a lot of gatekeepers in the way. Now, the people can decide what gets funded.” (Newman, 2011)

Still, further questions for scholarly and industry debate continues. Will it be profitable? How can a filmmaker, who makes a film online for free ever hope to see a profit, much less sustainability? For Hollywood, what affects the bottom-line ultimately, is the question they [studios] are waiting to see emerge profitable.

CONCLUSION

If it is profitable, how will this change the open democracy of the ‘wild west’ we see now in this new trend? Will it continue to be available and ‘free’ to all or be monopolised, packaged and sold as IPO to the highest bidder forcing filmmakers to go through yet another middleman to make their films? Will these online, participatory, transmedia interactions incentivize the audience to buy the finished product and any subsequent ancillary products associated with the creative product? What about future projects the filmmaker produces? Can there be added sustainability in this model? These questions and more that arise through research and practice will continue to merit further question and research. With arts funding continuing to dwindle, such as the reduction in grants and lottery funding, filmmakers have turned to crowd funding to finance their livelihoods – but will the audiences enable that to become a reality, or will the studio systems in place prevail?

“Creators, Distributors, and Marketers have accepted a dividing line between art and commerce, between content and marketing. By not engaging the filmmakers in how to use marketing tools within their narrative and how to bring narrative techniques to the marketing, we diminish the discovery and promotional potential of each film.” (Hope, 2011) On a larger scale, projects in this realm will emerge answering the question of how this new methodology of filmmaking relates to a wider economic, cultural, environmental and social scale.

AESTHETICS OF VOICE

Norie Neumark

This paper introduces key themes in relation to vocal aesthetics: voice as intersubjective, paradoxical, uncanny, intimate. It asks how voice is determined by and determining of spatial relationships and the way this affects memory and place. The paper explores specific examples from media arts to explore the performativity of voice and an 'authenticity effect' of media voices.

A number of key themes reverberate through the aesthetics of voice: paradox, uncanniness, intimacy, intersubjectivity, performativity, and memory and place. I'll begin with a brief introduction to these themes, turn next to modalities and techniques of voice in media art, and finally end with a discussion of voice's 'authenticity effect.'

Theoretical Introduction

Media artists have long been exploring the potentials and complexities of electronically mediated voice. From Yoko Ono screaming and coughing; to Alvin Lucier sitting and stuttering in his room; to Janet Cardiff leaving the room and the building to take us on sound walks; to Susan Philipsz with her locational singing – to name but a very few. Despite the richness of media art and the resounding way that sound studies burst into prominence in the 90s, vocal aesthetics has remained rather sub voce. And, although it has been several decades since Roland Barthes first invited attention with his concept of "grain of the voice," strangely, little general theoretical work on voice followed.

There was of course Derrida's significant work in the seventies, when he deconstructed the "self-presence, immediacy, identity, interiority" of vocal speech. [1] While this moved past invocations of voice as true, unmediated and authentic, the attention to vocal speech in relation to writing may well have played into a sort of binary, which inadvertently diverted theoretical attention. In recent years, however, critical writing has sidestepped such a binary, attending instead to an ambiguity of voice, a supplementarity, which resonate with Derridean concepts and draw out potentials of voice on which Derrida himself did not focus.

Key figures in this critical revival are Adriana Cavarero, Mladen Dolar, and Steven Connor, who share a sense of the complexity, the uncanniness, the difference and the paradox of voice. They recognise the in-between quality of voice – hinging between the physical (sonorous) and non-physical (signifying). [2] [3] As Steven Shaviro explains, in relation to Dolar's work: [4]

"Dolar... argues and demonstrates that the phenomenon of Voice is in fact far more uncanny and slippery, and already inclusive of difference, than Derrida gives it credit for. The voice always stands in between: in between body and language, in between biology and culture, in between inside and outside, in between subject and Other.... the voice is both what links these opposed categories together, what is common to both of them, without belonging to either." [5]

In its uncanniness – in Freud’s sense of *unheimlich* or unhomely – voice carries a trace of its ‘home,’ the body of the speaker, but leaves that home to perform speaking. Steven Connor is particularly intrigued by the uncanny voice of the double; he works with the *doppelgänger* figure of the ventriloquist’s speech because for him it evokes “the imaginary production of a secondary body, a body double: a ‘voice-body.’” [6] [7]

The doubling of voice undoes a ‘unitary’ subject – not just in relation to an individual subject, but it also disturbs a separation of two ‘unitary’ subjects. Here the work of Adriana Cavarero is particularly relevant, emphasizing the relationality of voice, in order, as she says, to prise apart any ‘unitary’ quality in Derrida’s figure of Speech. Cavarero engages with the alterity, relationality, and intersubjectivity of voice in order to get past the presence, which rightly, in her view, worried Derrida. [8] Relationality also resonates with the spatial relationship that voice creates, a shared space, a relational space, a doubled space – to which I’ll turn next.

Spatiality: Voice, Memory, and Place

While it’s a basic understanding within sound studies that sound operates not only through time but also in space – performatively in/forming the space it traverses – once again too little attention has been paid to how this plays out with voice in particular. Just as voice can be thought as a hinge between the sonorous and signifying, it also hinges between bodies and the spaces they inhabit: “...bend[ing] and connect[ing] rather than dividing.... facilitat[ing] openings and intertwinings (of doors, concepts, subjects, experiences, materials) rather than discriminating one side or one thing from another.” [9] And so voice hinges bodies and spaces, mediated and personal memory, memory and place; it connects speaking and listening bodies physically and affectively with each other as well as/through the spaces they share.

To explore this, I’ll discuss two works at Cockatoo Island, Sydney – a location resonant with its history as a prison and an industrial site and now an art and event site, tourist destination and camping ground. The first work is Susan Philipsz’ “The Internationale,” originally sited in an underpass in Ljubljana, during the 1999 European Biennial, Manifesta 3. The work was restaged in Cockatoo Island for the 2008 Biennale of Sydney (‘Revolutions - Forms that Turn’) in Turbine Hall – a large, abandoned post-industrial space. This is one of those works that takes you by surprise: What is the work? What is it doing here? Almost instantly, however, it seems completely sensible and at home. Yet, uncannily, of course, not at home, and thus disturbing our own location in the space. Philipsz’ singing of the classic workers’ anthem taps into the Hall’s physical memory, echoing through the space and through us. We feel ourselves differently in that space, sensing, somehow remembering its industrial history, as her frail, obviously recorded voice re-inhabits the space as if with workers’ memories – as if those memories haunt her voice, as if those memories haunt those enormous spaces, as if we overhear it in that space – a private, intimate voice wafting on that memory.

As always, Philipsz sings in a lone (lonely?), unaccompanied, palpably untrained voice – thin but reverberant. Here, it is an electronic voice emerging from one lone old speaker, calling you into the space as you approach. The effect of Philipsz’ recorded voice, evidently with little or no ‘art’ or ‘professional’ postproduction and no deployment of sophisticated speakers, is almost like an old radio abandoned somewhere in the Hall.

"When I make the recordings, it is important to keep the breaths and pauses in between, so that the song sounds natural and intimate. The idea is that when you hear a voice taken out of context in this way, your own sense of self becomes heightened while at the same time, you begin to experience your surroundings in a new way." [10]

For Philipsz this sort of production gives listeners the possibility to imagine it as their own voice. [11] For some it is a melancholy lament for revolutionary workers' hopes, for some it is exposed, fragile and brave, for still others, stirring and sad... Like any "cover" version, Philipsz is inhabited by and inhabits this song, bringing her own emotional response to it, but leaving us room to have our own.

Another, very different work – though like Philipsz', complex and ambiguous thanks to the voicing as well as being strangely in and out of place – is Richard Grayson's work, *Messiah*, in the 2010 Sydney Biennale. *Messiah* is located in one of Cockatoo Island's long tunnels – a transitional, hinging space, moving from the expansive and bright outside into a dark, intense, echoic domain. Off that tunnel, in a small low ceilinged dark room, plays Grayson's sound/video work.

Richard Grayson, who is interested in belief systems and the way that he sees Theology taking over from enlightenment rationalism, had emailed The Midnight Amblers, a group of musicians from Erskville, Sydney, to rewrite and perform Handel's *Messiah* as country music – revoicing and rescoring it so that we could hear the words anew. He asked the band to perform the work in a back yard, recording it with various DIY video cameras. When Grayson edited in Berlin, the sync turned out to be a bit off. He embraced this 'failure,' which served well to "foreground the artifice," He wanted to "bring back the weirdness and the spookiness... of something we take in a way as granted." [12] In its room strewn bizarrely with classic country and western hay bales, the out-of-sync mode – where sound does not seamlessly sub-serve the visual – add to the disturbance and heightened sense of awareness of the materiality of each sense. Itself dislocated from concert hall to suburban back yard to funky Berlin and now to this 'art' space, Grayson's *Messiah* is dislocating – mediating and enhancing our sense of the layered memory of the work and of this place.

Performativity

In both of these works the voice is not just performing, it is performative – performatively bringing forth memory of the place in which we find ourselves. The concept of performativity helps to take us beyond voice as straightforward performance or as the emission from some fixed unitary subject. Performativity is suggestive of the way voices DO and create, the way they change something rather than present or represent. Recalling Cavarero's attention to the relationality of voice, I would suggest that voice performatively evokes this relationality, bringing it into being rather than expressing it. What I'd like to emphasize here is the complicated and intimate intersubjective relations, which are staged as performative electronic voices lure the other, across space, even across the familiar space of the Internet.

The example I'll present is the networked performance of visual artist Barbara Campbell. The title of her durational project, *1001 nights cast*, [13] played with the *Tales from 1001 Nights* (The Arabian Nights) and with the fact that the net cast of this performance involved a webcast and a cast of over two hundred writers, who submitted their stories online for Barbara to perform each night. When you logged on to her evening performance, you saw only her mouth, giving prominence to the voicing, which storytelling involves. Framed by a story of a bereft bride wandering the world and greeted by strangers who give her stories "to heal her heart," the webcast opened with a view of Barbara's tongue, pierced and

wounded—like the heart of the bride— with a numbered tongue stud that signaled the number of the day/performance. I was fascinated by that mouth and tongue— a bit like a Chinese acupuncturist, searching it for deeper meanings, to see what it told about her, as it told her/other's stories. I asked Campbell about the choice to frame her mouth and foreground her tongue, in a conversation we had for Maria Miranda's forthcoming book, *Unsightly Aesthetics*. We discussed the mouth as visceral evidence of the physicality of the storytelling, and the importance of voice.

"Barbara Campbell: Of course the other thing about my tongue was that it had the tongue stud in it which had the number of that night ... I previously didn't have any kind of piercing.... that was another kind of reminder to me that I was carrying the project around or that it was inhabiting me or I was inhabiting it because to have a piercing in your tongue is very much like carrying an open wound because the tongue with all those enzymes from the saliva is always trying to heal itself..." [14]

This pierced and wounded tongue not only performed the stories but also performatively brought forth an intimate and wounded affective space that inhabited us and that we inhabited together during the ephemeral nine minutes performance.

Modalities and Techniques of Voice

Technique is somewhat like performativity—it shapes the object and technologies to which it ostensibly responds. Elsewhere I have discussed a number of bodily techniques or habits that shape voices as well as various modes of voice that throw the normal voice into relief—from the broken and stuttering voice to the scream.* Here I'll focus on the 'ground zero' of voice, breath.

Breathing is both a technique that enables and shapes voice as well as a mode in the whispered or breathy voice. As an example, I'll reference my own collaborative artwork. For a number of years Maria Miranda, and I have been working on a project called *Talking about the Weather*. In this work, we've been collecting breath, beginning with performative encounters with strangers on the streets. The project was animated by a desire to get the world's biggest collection of breath and use it to blow back global warming.

As Tim Flannery said in a few poetic lines, which were the inspiration—literally and metaphorically—for this project, the intimacy of breath is not just between people but also between people and the planet:

"The air you just exhaled has already spread far and wide. The CO₂ from a breath last week may now be feeding a plant on a distant continent, or plankton in a frozen sea. In a matter of months all of the CO₂ you just exhaled will have dispersed around the planet." [15]

Breath is a particularly intimate and alluring mode of voice. Like full-throated voice, of which it is an essential condition and part, breath is compelling and intriguing in that it is both bodily and not—it starts in one body and then connects to and communicates with another. I should emphasize that I am not talking here about the commodified intimacy of TV ads that have become all too familiar. Rather the performative intimacy and breath that I am interested in and that I hear in a range of artists works, is more strange and in-between. It is a way of speaking about a shared affective, inter-corporeal space that is beyond that of two separate unitary subjectivities. Following Alfred North Whitehead's idea that "the body is only a peculiarly intimate bit of the world," cultural geographer Sarah Whatmore understands the way in which "the corporeality of the body and of the world fold through each other." [16]

Breath, in its affective movement, performatively calls forth the space around us – it is “the very engagement between body and world from which these feelings arise.” [17]

Returning to the streets where we collected breath... With the weather feeling so frightening when we started this work in 2006, we needed to talk about it – obsessively, incessantly – to connect with people through this talk. We were asking people to contribute the breath they would use to talk about the weather to our project. The project felt to us like a very intimate communication in that we were asking people to contribute something personal and vital. We asked first for a minute of their time and then for their breath. We were calling upon and calling forth their generosity – and doing it in the middle of their everyday life, going somewhere on the street or in the park – we were inviting strangers to enter an imaginative, performative zone with us.

As you can imagine, gathering the world’s largest collection of breath is a big task and we realized we needed to extend our search as widely as possible, so in 2008 we took it into Second Life. Not having played in such worlds as a gamer, my experience there was unexpected. While at first appearance, and certainly if you haven’t been “in world,” Second Life may look like a familiar cartoon world, but this fails to account for the strangely magical, compelling and intense feeling of being there, including an intimacy with avatars, one’s own, and others’. While preparing for the breath collection events, I wandered around Second Life and noticed its voice activation mode. However after one attempt, I quickly realised that I did not want to use it, because it actually broke the intimacy of the connections between me and my avatar and others’ avatars. That is, voice activation, my own voice and others’, took me out of the world. In a sense, this is obvious – the avatar has its own specific materiality and therefore needs its own voice. The implication of this is that in order not to break the intimacy of the Second Life experience, what is needed is either a silent voice, full of potential, but not actualised, or a particular voice for your avatar, that you choose or make, like all its other body parts and clothing. That voice would speak from the avatar’s ‘embodiment,’ not ‘yours’, and thus maintain the intimacy. Thus, in our own work in Second Life, which we experienced as a public place in which to collect breath, we chose to work with the specificity of avatars’ connections and still have the affect of voice by using only breath rather than spoken word.

Authenticity Effect

To end, I’ll briefly discuss what I call an ‘authenticity effect’ of voice. Although in the heyday of postmodernism and in the early days of the Internet, artists and everyday users seemed to revel in the disruption of identity and authenticity, now with social media and YouTube, there has been a prevalence of direct address and ‘at home’ videos that many read as a desire for and return to authenticity. What I sense in this, however, is a performative voice, and, as Cavarero would remind us, when voice works performatively, it is not necessarily a call to (or from) essentialism or authenticity. What we have here instead, I suggest, is voice performatively evoking authenticity – an authenticity effect.

Contemporary artist TV Moore provides my final example here. Timothy Vernon Moore delightfully invokes the network between subject and machine as he goes by his very own, proper name’s initials, TV – ‘no pun intended’, as he says. In his work, we can find stunning examples of what Nicolas Bourriaud insightfully understood as ‘postproduction’ (Postproduction, 2002) or what Mark Amerika inspiringly explores as remix culture (REMIXTHEBOOK 2011). After months of playing around in the Australian Broadcasting Corporations archives, TV Moore found a documentary about marginal people, earlier recog-

nised as 'vagrants' or hobos. In the 60s, they were a different sort of nonconformist or outsider or prototypical artist-- alienated youth outside 'normal' structures of work, family, home. What TV Moore did for the work "The Forgotten Man" (2006) was perform the script of all the people in the documentary, from the snooty bureaucrats to the youth themselves to the ABC narrator. He re-performed their words, lip-syncing with amazing closeness. And so you watch this video in wonder and wonderment... whose voice are you listening to, why do they all have the 'same' voice? Is it the same? The lip sync is so neat, so 'authentic' yet...

And then you wonder, what has become of these characters, now ventriloquized, haunted, inhabited by TV Moore – or is it he that is inhabited by them? 'Inhabiting' is one of the key ways that Bourriaud understands the working of Postproduction artists.

"Artists actively inhabit cultural and social forms.... By refilming a movie shot by shot, we represent something other than what was dealt with in the original work. We show the time that has passed, but above all we manifest a capacity to evolve among signs, to inhabit them." [18]

TV Moore voices an inhabiting of the forgotten man and all who discoursed around him, to mediate them and our memory of them, but also to displace them and himself. In this way, TV Moore's work not only provokes wonder – about the forgotten man, about history, about documentary and about authenticity – but also provides a stunning final example of the intimate, uncanny and paradoxical aesthetic potentials of voice.

Acknowledgments

Introduction

This paper by Kim Newall and Charles Walker presents part of a larger, practice-led research project to develop a new understanding of sketching as a methodology for creative practice in the post-digital age. It will be presented through a reflective critique of the researchers' own hybrid, interactive, public performance-based practice.

The presentation will explore the concept and nature of sketching as a methodology utilizing a variety of media and operating across normative disciplinary boundaries. The research involves defining notions of the sketch as it relates to historical and contemporary practices; speculative design, documentation and critique of methods for sketching in differing media, material formats and contexts, and; the critical conception, development, application, execution and performance of sketching in the context of the researcher's own creative practice. The work draws on recent research in mathematics, physical computing and cognitive science to suggest that sketching shares with these disciplines properties that can externalize cognitive processes or reveal categories of thinking. [1] [2] Through linking sound and video-based work, hacking, physical modeling and archival material with traditional drawing techniques, the presentation itself takes the form of a real-time, improvised sketch. The accumulation of such sketches (archived in "sketchbooks"), in turn, informs further conversations between differing modes of knowledge and expression.

Defining Sketching

Definitions and descriptions of sketching have remained relatively constant throughout history and have emphasized its “speedy, exploratory, spontaneous, abbreviated, unfinished, indeterminate, fiery, contingent and/or disordered qualities often characterized by loss of control or openness to the unexpected.” Frederik Stjernfelt notes that elements within modern art have can also be seen to have focused on certain features of the sketch, “to isolate them, cultivate them and see them as just as essential – or even more so – than the finished work of art.” [4] In design disciplines, sketching is commonly seen as an interim activity; making images to assist in the creation of something more real.

The sketch has also been widely understood as an interim stage in the design process in different disciplines. In design-based or visuo-spatial processes, such as architecture and product design, sketching is frequently defined as “the making of images used to assist ... in the design of something else.” [5] It is important to note here that, in such domains, the terms ‘drawing’ and ‘sketching’ can overlap in meaning and sometimes can be interchangeable. For example, Eames, suggests that “the thinking space that you move to during the working process is drawing.” [6]

Yet, while Eames suggests that “drawing provides an essential means of prodding and probing, doing and undoing, glimpsing and maybe seeing and experiencing reality and virtuality”, he also makes a distinction between the “high and low focus thinking” that drawing facilitates. [7] High focus relates to logical and analytical thinking. However, Eames low-focus thinking is characterized by “loss of control, creative fancy and the ability to be receptive to the unexpected or fantastic” – a description that suggests an activity that others would recognize as sketching.

Current reading has also highlighted how some of key concepts and practices of sketching have recently been adopted by or transferred to different media.

Deanna Petheridge, for example, notes that while sketches are often characterized by medium: “a musical, literary, a clay, or an oil paint”, other disciplines such as mathematics, philosophy and science have also appropriated the idea of the sketch. [8] In recent years sketching has also been of particular interest to cognitive psychology, in as much as mental states and sketching “share certain properties which are imprecise, ambiguous fluid, amorphous, indeterminate etc and can reveal the thought process or externalize the cognitive” thus linking looking and thinking. [9]

Others have also used the duality of internality (i.e. mental) or externality (i.e. physical) in studies of creative practices or processes. [10] Eames similarly sees the sketch as a way of externalizing the thinking process “... putting down an idea before it floats away – or materializing an idea.” [11] Bilda, Gero, & Purcell have suggested that, for the expert artist, ‘externalizing’ the idea may not be necessary and that the process happens internally. [12] Scientific studies on sketching (for example [13]) have compared differences between the EEG brain signals of trained and non-trained artists. Anderson & Helstrup have studied the effectiveness of mental imagery with and without drawing support (perceptual assistance) in the visual synthesis. [14]

For Simon Downs, such activity is a “two way process” that “oscillates between seeing, thinking, remembering and imagining, controlling and being controlled as the image emerges.” [15] This suggests that process and product may continuously and simultaneously shift in the course of making

Defining Creative Practice

A creative practice is defined by continual evolution and change. There are many ways that an established practice can be contextualized. Reflecting upon the practice reveals that there is a method that has been employed from the start and that this method can be defined as sketching.

In Newall's practice both real and traditional media defined as analog and digital media (including computers) have developed together. The process of digital has informed the process of the analog media. While originally seen as separate; over the years they are emerging into a new hybrid space. Sketching has played a pivotal role in the emergence of this space.

The traditional analog media employed include paper, card, pen paint, watercolour, tape. The digital media used include, computers, programming, microcontrollers, projection, video and electronics. Both these media domains however are constantly being augmented for different sketches to include music videos, video games, public interactive installations, VJing, live audio/visual shows, theatre shows, art gallery installations, and street art. Some of the above are formal finished works; others are works in progress that are always changing and are not seen as a piece of work. Often without a title they might happen spontaneously, in casual acts such as street art stickers.

Fundamentals

Some fundamental methods were established in the early period of the practice that still drive the current work. In the 1980s, with the advent of the microcomputer the availability of the computer at home for the non-professional provided the opportunity for anyone to experiment with computers and programming - in effect, to become a 'programmer'.

The low storage capabilities of Newall's first computers forced him to develop programming skills by working around limitation. Using what was available, with limited but evolving skills and knowledge, exploring the possibilities and gaining more knowledge and skills. In this process, Newall developed the capability we here call sketching, in which the sketch is a product or artifact in itself.

From following simple examples the practice developed to produce very simple programs that made simple drawings on green and black screens. When the computer was turned off the drawings were no longer there. They could only be reproduced from memory and in this process they did not always come out the same. These sketches were a set of commands or instructions that were executed in a linear fashion however having a visual, graphic outcome was very important. The simplicity and naivety of these 'sketches' became a defining characteristic of his practice and the basis of a new 'non-expert' expertise.

In the 1990s the Graphic User Interface (GUI) allowed computers to be used more efficiently by non-programmers. Examples of this commercial software include Adobe PhotoShop and Alias/Wavefront Maya. In recent years open source software, such as "Processing" and "Openframeworks" have again made programming accessible for creative and hobbyist enthusiasts, and has enabled programs to be sketchable.

A similar understanding of process has informed the design of a method of sketching to be explored with computer code. One result was *Processing*, a software program developed to encourage artists and designers to use computer programming as a means to create work (processing.org). The creators

of *Processing*, Ben Fry and Casey Reas, named the files that are created by the program, *sketches*, a clear signal that enabled artists and designers to relate to programming through techniques they were familiar with. The idea being that the computer program can be treated like a sketch; as something that is malleable and that can be pushed and pulled like clay, or drawn and erased like pencil. This notion that code can be put down as if by impulse, as a 'what if I do this?' kind of operation, suggests that the program does not need to be 'designed' top down, then 'executed' to perform a specific action or set of actions. Rather, programming can be used with a bottom-up approach, as tool for exploring or discovering, analogous to what happens in traditional forms of sketching.

Processing is a designed platform upon which the sketch may be made, performed or take place. It hides details that the sketcher does not need to know about. Technical requirements are minimal, so the non-technical user does not get stalled by having to deal with technology. The intention is to approximate the more familiar or 'natural' relationship of paper and pencil.

A similar concept - based on *Processing* and aimed at artists and designers rather than technical people - informs the *Arduino* platform - an open-source electronics prototyping system based on a few basic, flexible, easy-to-use components, including the microcontroller that can be programmed from an *Arduino* program language.

The tools that have been developed over the years that have allowed the non-expert access to technology, have enabled Newall to use these tools for sketching. Fostering an ability to try things out with fluency and intuition without being hindered by the complexity of technology.

Circle Hacking

Circle hacking is another example of digital sketching. It began by using an example in a computer manual on how to draw a circle in the middle of the screen. By changing the numbers in the equations to see what would result without knowing what was happening mathematically. The images were 'Spirograph' like drawings. The process of iteratively changing small bits of the code enabled the discovery of different, but related patterns.

This was the start of exploring what would happen if things were changed without a preset plan or idea. That hacking is one of the central ideas that has also lead into or applied to the traditional media. This was a fundamental way of thinking by beginning to change things to explore the possibilities with the media that was being used.

Graham describes his method "I tended to just spew out code that was hopelessly broken, and gradually beat it into shape" then he concludes "If I had only looked over at the other makers, the painters or the architects, I would have realized that there was a name for what I was doing: sketching." [14]

Hacking can be applied to any type of code or data with include different types of media and disciplines, Wark define hacking neatly in the following quote:

"Whatever code we hack, be it programming language, poetic language, math or music, curves or colourings, we create the possibility of new things entering the world. Not always great things, or even good things, but new things." [15]

This is one of the ways of summing up the creative practice described in this paper. Hacking is a process of bringing the intangible and the abstract into the real world as Wark explains

“To hack is to release the virtual into the actual, to express the difference of the real.” [16]

The process of hacking that was discovered in the hacking circles has been applied into the sketching with analog media. Changing/altering to find out what will happen. Hacking as a form of sketching applied to different media both analog and digital is key to Newall’s creative practice.

Sketch Books

The following section and visual presentation summarises Newall’s practice to the present time, highlighting some of the key concepts. A collection of sketches that included different media were developed in the early years, and now form the basis of current creative practice. A strong archival practice of maintaining sketchbooks also developed using traditional media or analog media such as pencil, ball-point pen, watercolour, etc., on paper. The sketchbooks evolved using digital printouts as starting points for further sketches and the digital and analog began to merge in new ways.

In the mid-nineties, Newall explored real-time 3D computer graphics that he began to label as ‘Sketches’ or ‘Drawings’. The idea of ‘performing’ came out of the act of manipulating these drawings; hours were spent exploring possibilities, often accompanied by responding to music in real time. A handful of videotapes were produced that he came to think of as an equivalent/alternative to sketchbooks of drawings. VJing was introduced to his practice at this time; this provided a way to perform live in front of any audience and could include projecting the mix of these videotapes in parallel,

The creative practice thus seeks to develop a conversation between different modes of artistic expression. He has come to realize that an original language is emerging from his search for further possibilities for interaction, mixing analog and digital together across virtual and real media, extending the “what if” question.

Animations and/from drawings, manipulated, come together as performance in the form of VJing; in turn, suggesting the performance itself as a form of sketch. Indeed, in the field of performance, the term ‘sketch’ and related ideas about ‘improvisation’ could be used to refer to a quality of sketching in terms of exploring the possible in real time.

Recent Work

The exploration of this relationship and a type of mixed reality that is ‘in-formation’ - always ‘in process’ and neither real nor virtual - has continued up to the present time. Examples include the interactive public projection work “Urban Life” (2009), the works for “Vending Machine” at Splore Festival (2010) where digital designs were sketched and materialized into real attachments for the human body and “Evolutionary Experiments” at MIC Gallery, Auckland (2010) where creatures developed from “Sketching” with software, hardware and cardboard, created and occupied a new space that would not have been possible in either digital or analog form.

The interactive work “Roosting” (2011) consisted of 12 birds on 12 TV screens in a 3x4 grid that reacted to movement in front of them. So how can sketching relate to the work? The answer is that the users

sketch with the work, not in the literal sense but in an abstract way. Some users would mimic the bird's booth with sound and movement on screen to see how the birds would react. This is exploration of what the work does, causing the user to improvise or sketch with the characters on screen. This opens up possibilities of how user interaction can be seen as sketching for future works

Conclusion

Many things are possible. There does not always need to be an outcome. The sketch enables technologies both analog and digital to merge. The sketch is not limited or restrained as a method. It is adaptable; it can operate at different levels and in different ways. Sketching can be done in any media with any technologies with many different outcomes. Sketching is an exploration of the possible, and can become a record of impossible. A sketch can exist in a moment of time and become an artefact. There is a time and place for the work to be what it needs to be: Sketch.

THE HIDDEN HISTORIES OF OBJECTS: PROVENANCE, STORYTELLING AND TAGGING TECHNOLOGIES

Simone O'Callaghan & Chris Speed

As part of TOTeM, a £1.39M project based around the internet of things, this paper explores linking creative artefacts to stories of their inception, using QR codes.

Introduction

This paper explores storytelling methods to follow the lives of objects from their first inception to the narratives they collect along the way. It is part of TOTeM [1] a £1.39M research project based around the "Internet of Things" [2], which opens up new ways of preserving people's stories through linking objects to the Internet via "tagging" technologies such as QR codes.

The process of appending immaterial data such as textual, video and audio stories, offers a significant additional dimension to the material attributes of an object. Hand produced creative artefacts already transcend a material value because of their individual characteristics and their reference to social and cultural frameworks. As the emerging technology of the Internet of Things supports the tagging of more and more objects, things will begin to accrue an immaterial data shadow that will begin to outweigh its material instantiation (Sterling, 2005).

Project Partners at The University of Dundee and Edinburgh College of Art have been unpacking these notions through creative practices, working both as, and with artists to embed the Internet of Things in a more social and interpersonal context

A rolling stone DOES gather moss

In April 2010, the TOTeM project team launched the web project www.talesofthings.com. The site offered a simple but novel approach to recording social histories and a playful critique of the tagging culture that is associated with the emerging concept known as the 'Internet of Things'. Our platform allows anybody to attach web content (text, image, video and audio) to an artefact through the generation of a unique QR barcode that the owner is encouraged to stick to their thing. When scanned by somebody else using a smart phone, media is launched and the object can be seen/heard to tell a story about the memories that it is associated with.

Our reasoning was simple, that the existing public use of tags (RFID, traditional barcodes and two dimensional) is based upon a 'read only' relationship. And although the web savvy amongst us can generate a QR code and associate it with web-based media, for many people the scanning of codes is a practice reserved for people working on super market checkouts and in passport control booths. As well as offering a place in which unique codes are generated and allow stories to be associated with artefacts,

TalesofThings allows any other beholder the ability to ‘add a tale’ to someone else’s ‘thing’. By scanning a tag through the phone App, or by visiting the website, artefacts become ‘writeable’ and ‘open’ to further association. This is a critical dimension to the projects politics, that lessons learnt through Web 2.0 should be integral to any Internet of Things.

Following our launch last April the website began accruing stories that were associated with peoples actual material artefacts. However as the immaterial database grew it became clear that we needed an event that allowed the material artefacts to become an interface to our internet of things, rather than online repository of stories. RememberMe at Future Everything offered this context. The RememberMe artwork was a collaborative project with the Oxfam shop charity shop, in Manchester. During Future Everything 2010, a research assistant based in the shop, asked people who dropped things off to tell a brief story about one of the objects into a microphone: where they acquired it, what memories it brings back and any associated stories. These audio clips were then linked to an RFID tag and QR code and attached to the items as they joined the shop’s stock. Visitors to the shop, including conference delegates were able to use bespoke RFID readers, or their own smart phone to browse artefacts that were displayed amongst the many thousands of other objects. Labels highlighted the RememberMe objects and once triggered, speakers located in the shop replayed the previous owners story, evoking a ghost from the past. Once tagged the objects were in the public domain for purchase by other members of the community, and the project’s iPhone and Android apps allowed new owners to access old stories but equally importantly, add their own.

This material ‘turn’ in the life of the project readdressed the balance of where the immaterial data was located. Instead of being accessed through a web interface, the RememberMe work explored the potential of the TalesofThings project to manifest a social Internet of Things that is situated in the event based context of exchange. An exchange of things and stories that contests many of the habitual consumer practices that have formerly defined concepts of value, quality and the destiny of artefacts. A year later we wanted to exploit the projects ‘write back’ feature and see if we couldn’t tip the balance between immaterial and material in favour of the former. During Future Everything 2011 the team developed a follow up project entitled RememberUs. The project consisted of two shops that acted as supernatural portals to the Internet of Things. Visitors to the Oxfam Emporium were invited to ‘let go’ of memories that are associated with particular things by attaching stories to our memory vessels, moments later in the Oxfam Originals shop just down the street, people were able to ‘pick up’ memories when they are associated with another ‘thing’ that they chose to buy. Upon leaving the shop, buyers found that the item that was ‘new’ to them was associated with a host of old memories, exploding the assumption that a rolling stone gathers no moss.

Artists Stories

When thinking about linking stories to objects, there always has to be a “first story”, the one of how a thing came into being. The TOTeM project team is collaborating with creative practitioners to explore some of these first stories to establish platforms for provenance, where storytelling methods are examined for defining and capturing provenance. Looking back at the history of old objects, as well as forward to the possible futures of new objects it is also a means of providing legacies of provenance for future generations.

In tagging art, design & craft objects, the QR code acts as a “digital makers’ mark” with the potential to hold far richer data than traditional marks. Inspiration for the object’s creation and its maker become the key focus, rather than facts about production and manufacturing. Working in a similar way to social networking sites such as Flickr, users of TalesofThings can comment and build upon existing stories with the potential to create a crowd-sourced bank of knowledge about any individual object. This then has the potential to provide future generations with artworks, craft and design objects, which have integrity and a traceable heritage. Whilst the provenance captured by the data shadow of commercial things may be logistical: price, temperature, best before dates etc., information provided by artists and designers has the potential to provide significantly more evocative stories that may change entirely the perception of an object.

In 2005 YBA artist Simon Starling, won the Turner Prize for his work *Shedboatshed*. It appeared to be an ordinary shed and not particularly noteworthy. However, knowing that it was a shed found in rural Switzerland which Starling took apart, made into a boat, floated down the Rhine to the Kunstmuseum in Basel and then reconstructed back into a shed, has made the work, and winning of the Turner prize for it, objects of controversy in both the art world and mainstream media. Paul Shephard, a champion of Starling’s has said of the work: “One of the interesting things about this *Shedboatshed* is that the thing you’re looking at isn’t the whole work. Now this is always true in conceptual art generally because conceptual art uses its artwork to illustrate some other idea. I think what’s interesting about Simon’s work is that he doesn’t deal in concepts so much as actions - so the work is evidence of action having taken place which is slightly different.” (Shephard, 2005)

The idea that a particular action has taken place is pertinent to many objects, but we only know about these actions and the reason for something being identified as an art object if the artist tells us. With tools such as TalesofThings, there is a platform for makers to tell these stories, in an arena that facilitates the conveying and validating of peer reviewable truths. But these can also be subverted, allowing for fictions to be written and for myths arise, both about the objects and their makers. For how do we know that Starling really did float his *Shedboatshed* down the Rhine? The stories woven around creative artefacts also become a reflection of the persona or identities that a maker chooses to construct and portray in the context of their creative practice.

Such myth-making is not new but what is interesting is that by using tagging technologies that allow others to comment on an object’s stories, these myths can be exploited. Take for example, Andy Warhol, around whom myths have evolved. What does artwork made by Andy Warhol actually mean? His screen-prints are iconic, but, in contrast to the Congress of Artists’ definition of what constitutes an original print, Andy Warhol did not make original plates, work the stone, or in his case create even the original screens for his prints, yet he is still recognized as the artist. He did, however, add the “final touches” such as blotting lines to give a less mechanized feel in the final prints. This highlights that even an artist such as Andy Warhol recognized a need for something that resembled the touch of the artist’s hand, even to the point where works were signed. Through in true Warhol style, he was not the one to sign them, his mother was, and when she tired, another artist from The Factory took over. (Buskirk, 2003)

Imagine if those artists working in The Factory were able to tell the stories of the prints they worked on through tagging the artworks, and then allowing others to add to those stories. We can assume that many of those in The Factory were bound by loyalty to Warhol, but it would only take one disenchanted

person to open the floodgates. What would Valerie Solanas done have done with such capabilities in her hands? The myths of Warhol that we are familiar with today could have been very different.

Artist, Claire McVinnie, who like Any Warhol creates artworks using screen-printing, has been profiled in a collaboration with Dundee Contemporary Arts Print as part of a case study examining printmakers using QR codes as digital makers' marks. Over the space of 9 months, Claire has written about her works on TalesofThings, tagged and exhibited them with QR codes and has been filmed telling the tales of her works. Through these activities, the identity as an artist that she wishes to convey is being constructed for an audience who, quite often, may not share the same space and time zone that she does.

Tacitly, Claire is aware that there will be occasions where people will view her telling stories in a space that her works inhabit but that she does not. This is the phenomenon of tele-presence, defined by Lev Manovich as "representational technologies used to enable action, that is, to allow the viewer to manipulate reality through representation...the essence of telepresence is anti-presence" (Manovich, 2001). The art objects become signifiers of Claire's identity as an artist, whilst the digitally mediated content delivered to a users' mobile device can be seen as one way of confirming this in the absence of her actual physical presence. Such a validation can then affect the actions of those at the receiving end, for example the telling of her story may influence the purchase of one of her prints exhibited in a gallery, which may not have otherwise been purchased had the story not been told.

When discussing the filming of Claire's work and stories, she suggested that she be filmed at the print studio where there are screen-printing beds and the tools that she uses to make prints. She also has another studio where she preps her files and works on designs before actually creating the final pieces. The print is studio open-access, often noisy and full of bustle, whilst her own studio is a calm and quiet haven. In communicating her identity as an artist she chose to be filmed in the place where she has a more public image, rather than revealing her personal space on camera. This could be seen as her way of editing what is considered appropriate to convey as a professional artist, whilst remaining protective of a space that could reveal more a more intimate aspect of her working life. Typical of artists in the print studio, Claire wears an apron, one of the many communal aprons that the artists here share, its stories smudged and smeared across it in a colourful splatter of dried ink. The ink is a testament to the numerous artefacts that the apron has witnessed coming into being and suggests a more experienced artist than if the apron were pristine and unmarked.

Through the use of digital media storytelling methods to construct a rich identity of the artist as a person, the stories can also illustrate the emotional investment of the maker in that creative artefact. In her screen-print of New York, Claire tells of how she went on a college trip there in 1995 and took photos from the Empire State Building, but was so disillusioned with the foggy weather she didn't bother to get them processed. Years later she found the film and did eventually process them, realizing that with photoshop she could claim back parts of the image that she had lost to the mist and rain. She also admits that "This is one of the first screen-prints I even did, so I was still just learning". It was also the first artwork that she chose to talk about when being filmed, which considering the strength of the image and the success she has had in selling it, suggests that the work is seminal in her journey as a professional artist.

Enhancing Aura

During the study of artists working at Dundee Contemporary Arts, the integrity of the artist as a print-maker is articulated through many of their stories and is poignant in Annis Fitzhugh's text-based entry on TalesofThings accompanied with an image of her work *Cancellation Proof*: "when a limited edition is completed, the plate or block is defaced, often with a cross, so that no more prints may be made from it. The plants represented are all on the Red List of endangered species." (Fitzhugh, 2010)

This entry implies that the edition is "authentic" because Annis created a cancellation print for her edition, a "proof" that the edition is limited. The content of the artwork, like the print itself, is endangered, rare and limited. Annis' entry also explains printmaking processes to non-printmakers and the comment following up on this by a user called "froggo" shows a discourse beginning to emerge about the work, and about printmaking practices, when they write: "That's sad that a lot of nice images get defaced in such a way :(" (ibid) One can infer that froggo is not a printmaker, but that they appreciate the print that was cancelled. This comment is also thought-provoking in how accepted norms and "good practices" in printmaking can be perceived as destructive by those outside the field, who are unaware of the critical debates surrounding authenticity and originality of the print.

By examining artefacts and the stories that creative practitioners use to express how their objects came into being, the frameworks in which they are viewed enables a privileged insight into maker's creative processes, experiences and emotional states. Through tagging technologies, this "mobile augmentation" of art and design objects, where the physical has digital and therefore multiple presences, Walter Benjamin's notion of "aura" comes into play, "One might generalize by saying: the technique of reproduction detaches the reproduced object from the domain of tradition. By making many reproductions it substitutes a plurality of copies for a unique existence. And in permitting the reproduction to meet the beholder or listener in his own particular situation, it reactivates the object reproduced." (Benjamin, 1934). In her study of Le Courbusier's archived drawings at the Le Fondation Le Corbusier in Paris, Susan Yee of MIT describes her experiences as she handles his largest drawings: "All I could think about was that this was Le Courbusier's original drawing. It was meticulously hand-drawn, but the drawing was dirty. There were marks on it, smudges, fingerprints, the marks of other hands, and now I added mine. I felt close to Le Courbusier..." (Lee, 2007). On her last day in Paris she discovers that all the drawings have been collated in a digital database and she mourns that "the scans for the website gave me nothing to touch" (ibid).

Benjamin's concepts come from experiencing the "original" work first hand, being able to see the marks that the artist has made in their exploration of the medium in which the work is created. The same applies for any object and the memories, bumps and scratches that it collects on its journey. Although the Internet of Things, and mobile tagging technologies demand a need for the digitisation of artefacts, one could argue that when an object is tagged with the previous owner's memories or a creative artefact is tagged and augmented with the artist's voice, the "aura" has the potential to be heightened and enhanced rather than lost.

ACKNOWLEDGEMENTS

This work was made real by the TOTeM research team whose Co-investigators are (in alphabetical order): Maria Burke, Andrew Hudson-Smith, Angelina Karpovich, Simone O'Callaghan, Jon Rogers, Chris

Speed. Additional team members are: Ralph Barthel, Martin De Jode, Kerstin Leder, Arthi Manohar, Jane McDonald, Duncan Shingleton.

Thankyou also to the artists and DCA Print Studio and in particular, Claire McVinnie and Annis Fitzhugh who were so candid with their stories.

NETWORK MEDIA: EXPLORING THE SOCIOTECHNICAL RELATIONS BETWEEN MOBILE NETWORKS AND MEDIA PUBLICS

Rachel O'Dwyer

Considering 'media publics' as an assemblage of ICT networks, technological devices and human collectives, this paper explores the complex conditions across social and technical spheres that influence the character of contemporary media production, consumption and distribution on the go. Critiquing the current study of sociotechnical collectives it considers tactical media as one alternative approach.

Introduction

This paper concerns the sociotechnical relations between Mobile Information and Communication Technology (ICT) Networks and 'Media Publics', using a term to describe collaborative and non-proprietary practices emerging around the collectivised production, consumption and distribution of digitally networked media. In light of the ongoing integration of ICT networks into cultural practices, this paper calls for a critical theory of sociotechnical networks.

The following discussion critiques the epistemic frameworks available for the study of networked media, and in particular the intersection of technical and social apparatuses occurring around online culture. While the network as a cultural trope is prevalent in critical theory, the technical characteristics of network media (Infrastructure, topology, protocols and standards) are frequently 'black-boxed' in favour of overarching discussions of an immaterial network culture as it relates to broad frames of governance, subjectivity and political economy. By eliding a deep consideration of the material substrate of the network and subsequently the many ways in which media publics are generated in diverse relations between a range of actors, contemporary theory has failed to explore the complex ecologies of sociotechnical networks. Instead, in the literature of social media, we continually encounter linear causal models of analysis that all too easily equate centralised systems with proprietary cultures and decentralised networks with democratic media practices, failing to attend to the many nuanced ways in which the apparatuses of a communications network constrain or alternatively enable the formation of autonomous cultural collectives. If we really wish to explore the possibilities to design, implement and scale networks that support collaborative culture, we require a theoretical framework that traces agency through all layers of the network. Such a framework is still absent from network culture.

This theoretical gap will be illustrated with reference to an obviously sociotechnical assemblage, drawing on recent prototypes for episodic networks, a species of mobile ad hoc network that uses human proximity rather than fixed infrastructure to distribute data packets. Superficially these networks represent an ideal platform for the kinds of user-generated practices commonly associated with utopian accounts of media publics, suggesting a network topology that is fully distributed, supportive of peer-to-peer communications and dynamically self-organising. However, through an iterative analysis of the relations between different layers of the network, this paper explores how algorithms immanent to the substrate of the network expropriate user-generated content, monitor activity, shape future network behaviour and ultimately produce the network in ways that might advance proprietary interests and limit the agency of media publics.

This study demonstrates the need for appropriate frameworks and methods for research into networked media. While a number of approaches from technology studies and complexity are useful for the formation of a network media theory, this paper will conclude with a consideration of tactical art projects as one suitable approach.

Network Cultures

This discussion is situated within the disciplinary remit of 'network cultures' understanding new online media practices as endemic of a broader societal condition in which a distributed network topology supplants centralised and hierarchical models as the dominant cultural, social, political and economic organisational logic.

It is necessary, therefore, to begin with a brief disambiguation of the term 'network' as it is used within this paper. There are growing ambiguities around the term 'network' arising from its application across different disciplines: referencing a technical assemblage such as transport or electricity, or in the sociology of organisation, used to quantify institutions, markets and states, whereby the network represent an informal way of associating together human agents. In the context it is applied in this discussion, which draws from Manuel Castells onwards, the two meanings merge, since the 'network' becomes a privileged mode of organisation thanks to the very extension of Information and Communication Technologies. [1] A 'media public' therefore, as an assemblage formed around the production and distribution of online culture, is an example of one such network, including the producers and consumers of content, the content in question comprising text, voice or rich media, and the underlying technical assemblages which facilitates its transmission. This is comprised of contingent logical and physical strata; the higher level protocols and services implemented in software, and the lower substrate network, comprising tangible hardware such as user devices, transmission technologies and the available physical resources such as spectrum, bandwidth, real estate, man power and energy.

It is clear therefore that the 'media public' is a complex assemblage comprising not only human relationships but a whole range of logical and physical resources. These may be mutually supportive, but just as often they are structurally contradistinctive or otherwise opposed. Where the media public as a progenitor of a rich online culture is contingent on technical infrastructure, our analysis should also proceed towards the complex and iterative relations between network layers, in particular the mutual enforcements or structural antagonisms that might alternatively constrain or enable the emergence of an autonomous cultural collective.

Media Publics

Common terms for media publics such as Howard Rheingold's 'Smart Mobs', Mimi Sheller's 'Mobile Publics' and Kazys Varnelis 'Networked Public' model all converge on the idea that recent technological transformations inherent to ICT architectures herald a correspondent shift in the collaborative media practices developing over these. [2] [3] [4] The 'media public' emerges as a counter-capitalist ideology whereby technical affordances in the network are thought to disintermediate controlling interests and facilitate an autonomous networked information economy. [5] These affordances include a consumer electronics culture that places the means of immaterial production in the hands of a majority, the primacy of distributed topologies and non-discriminatory protocols over traditional centralised communications, and a consequential shift from the audience as passive consumer, towards the ambiguous subjectivity of the 'produser' as an active agent in non-proprietary culture. [6] These broad transformations

are in turn associated with peer-to-peer economies, an inherently democratic mode of governance, an invigoration of the public sphere, and the emergence of an online collaborative culture sustained through voluntary production over the network.

With the emergence of Web 2.0 platforms that emphasise collaborative production and content-centric architectures, and the subsequent progression of these activities beyond the desktop to mobile and pervasive contexts, the advocates of online collaborative culture identify a relative increase in the role of nonmarket practices taking place around the collective exchange of mobile information, knowledge and culture. These include frameworks such as Open Source, User-Generated content, DIY Production and Grass Roots Media. These theorists see the immaterial culture of the media public progressing outwards into hybrid space, as an online culture that has potential social, juridical and economic implications for real world cultures and material economies. Mobile networks are a space in which this intersection is thought to be particularly prevalent, representing a point of intersection between virtual and physical practices.

This paper identifies certain issues with the theoretical frameworks that underpin the dominant ideology of media publics. These are based on two interrelated criticisms:

The first claims that cultural studies of online media publics avoid a full consideration of the technological infrastructure underpinning online culture. While ICT technology is the necessary precondition for a networked public, its physical concatenations are again and again rendered immaterial in favour of the generalised tropes of links, webs and globalised interconnectivity. Network cultures frequently fail to take into consideration the politics of the material substrate, its counter purposes, proprietary origins and deep structural organisation, promoting instead a benign equivalence between superficial traits of the technical architecture and modes of autonomist social organisation. Too often the technical system is taken at face value and its agency is not fully explored.

Tensions frequently emerge between an online culture based on voluntary production and loosely woven collaboration and the organisational and economic logics of the material systems that underpin these media publics, such that a non-proprietary culture at a content layer might be subsumed, expropriated or otherwise conflicted by proprietary or controlling interests underpinning the network. An example of this can be gleaned from a consideration of current mobile networks. On the one hand, the distribution of networking capabilities within everyday spaces and contexts is frequently associated with new forms of collaboration, political economy and public activism. At the same time, it is increasingly clear that these networks are also aligned with new economic frameworks and powerful forms of governance that thrive on decentralisation, monitoring behaviours, extracting surplus value from user-generated content and otherwise surveying, exhausting and constraining online cultural activities. The reality is not a dialectic in which dominant or subaltern forces are externally located. Proprietary and non-proprietary, liberatory and controlling agencies are endogenous to the network, and frequently operate in symbiosis, producing complex and emergent behaviours.

Which brings us to our second criticism, namely an identification of alternatively social or technologically deterministic analyses in the literature on media publics. Research in social media continues to employ linear-causal models of analysis that all too easily equate centralised communication technologies with proprietary frameworks and the distributed topologies of communication networks with inherently democratic media practices, failing to attend to the many ways in which collaborative online culture is generated in diverse relations between human and non-human actors. Even as the research pays lip service

to the language of complexity or critical reflexivity, studies fail to account for the dynamic and iterative qualities of sociotechnical networks.

Episodic Networks

The complexity of the mobile publics can be illustrated with reference to an obviously sociotechnical assemblage: forms of mobile ad-hoc, and delay tolerant networks that are often termed episodic, opportunistic or pocket-switched networks. 'Episodic' describes a network whose topology is constantly performed and negotiated through pair-wise connectivity between mobile devices. Unlike the majority of networks that rely on relatively stable material infrastructure in the form of fibre-optics, cables, base stations and routers etc., episodic networks are by definition contingent, their elements dynamically reconfiguring based on necessity and circumstance. Episodic networks route data through a network of mobile peers. Each peer (human) forms a node within the network, transferring data from device to device without the aid of a centralising relay structure. Nested in human interaction, the concept of the 'people as network' is increasingly resonant. These networks utilise everyday patterns of mobility and varied and sporadic forms of connectivity between strangers and familiars in dense environments to leverage a dynamic network topology for the distribution of media content. The value of the system is correlative with the user's social connection to others in a networked space. In principle they facilitate the production of self-organising groups, bypassing the hierarchical structure of traditional mobile communications to form peer-to-peer reconfigurable communications with individuals in proximity to a user.

The episodic network is discussed here more for its heuristic value than its relevance to current network architecture. However, there is evidence of the increased relevance of such topologies in future mobile networks, with 4G and LTE supporting various mesh-like topologies that resemble ad hoc modes of connectivity. Initially theorised in the 1970s as an emergency service and valorised in the early noughties, they are increasingly discussed as a viable component of future mobile media architectures. Principally designs for episodic networks concerned the exchange of text-based files or operational instructions for proximate devices in a user's environment, but more recently following the exponential growth of content-centric activities on mobile and wireless networks, the episodic network has re-emerged as a potential strategy for the dynamic exchange of rich media content in real spaces and a form of data-of-flooding for increasingly congested wireless network spaces.

Undersound is a proposal for music exchange on the London Underground. [7] It utilises an episodic network topology within the transport system itself for the opportunistic exchange of audio files. These files are associated with static terminals in train stations throughout the city. Users can upload and download tracks at these centralised points and exchange them using software on mobile internet devices such as a phone. Users on the tube can browse each other's playlists in transit and choose to share and distribute music between devices. The system also includes algorithms for monitoring media consumption/distribution patterns and the propagation of files throughout the network. When a user re-connects to an upload point at a station, therefore, metadata concerning file exchanges and relational patterns are also automatically uploaded to the network and subsequently used to model sociality and media-exchange occurring within the underground. The designers of Undersound theorise this data as informative to the future design of social media networks that utilise context-aware information to enable file transfers and opportunistic sharing. [8]

At first glance these networks are every promising architectures for the kinds of user-generated practices that are typically associated with optimistic accounts of media publics. It can be argued that the distributed topology of the network and the nesting of technical agency in everyday environments leverages a public brought together around the dynamic exchange of information and rich media content. But such an easy analysis fails to account for the complex characteristics of the network that emerge through the relations between the social and the technical. Through an iterative analysis of the episodic network, we can explore how social behaviours and everyday habits are aggregated by proprietary devices and platforms and subsequently utilised: as valuable metadata for proprietary interests, as dynamic information that informs decisions at the logical layer of the network, and as quantitative research that informs the design of future network architectures.

A large amount of information can be gleaned from episodic networks. These include a whole range of user-generated content both consciously and unconsciously produced from demographic, geographic, social and even biometric data. In terms of social network analysis, information about everyday sociality; who we come into contact with and for how long, what value we, as individuals, offer as a node in the network and broad mobility dynamics concerning our movement as a group are all important data for determining the reconfigurable topology and routing protocols implemented by the network, its efficiency, and overall performance. Secondly, meta-data collected through often deeply embedded processes running on proprietary devices or fixed points of infrastructure are lucrative forms of user-generated content. Just as this data forms the economic base of fixed internet conglomerates such as Facebook and Google, this mobile data is associated with a significant market value, further leveraged by context and geo-spatial data provided by a mobile network. Mobile episodic networks therefore provide ideal platforms for the expropriation of contextual metadata that can be sold to external corporations looking to enhance, rationalise and personalise marketing and advertising,

This raises some questions: How do these systems quantify human sociality as inherently productive of valuable? What kinds of collaboration or sociality are subsequently encouraged or normalised? How is the production of user-generated content on such a network used to advance the interests of corporations, expropriate the value of creative practices and ultimately constrain the formation of an autonomous culture?

The situation we witness therefore is not only the creation of new social practices, but furthermore, the controlling, monitoring and expropriation of these through mechanisms facilitated by the architecture of the network itself.

Conclusion

In the highly mediated spaces of online culture, it's clear that we require a critical awareness of the sociotechnical geographies of enablement and constraint operating across all layers of the network. The previous illustration still only gestures towards this complexity. We require approaches that can move across methods and trans disciplines traditionally aligned with the humanities or the sciences and appropriate complex, emergent behaviours.

While a number of approaches from the Philosophy of Science and the Science of Complexity provide useful starting points, the previous discussion points toward the need for practical methods that are themselves immanent to the network. Described as an intermediary between artistic and ethico-political activism, tactical media provides a frame from which to categorise a variety of extra-curricular methods

through which a sociotechnical system might be made visible. These include practices such as the tracing or mapping of connections, the fictionalisation, inversion or reflexive exploration of networks, and the misuse, recontextualisation, exploit, or abstraction of economic, social and political processes through technological media.

Umbrella.net for example is an episodic prototype developed by a team of artists working in the Network and Telecommunications Research Group in Trinity College Dublin[9]. The work in question comprises a coincident network in which everyday items, in this case an umbrella, activate an ad hoc network when they are deployed in public. The network itself, from a commercial perspective, can be theorised as a solution without a problem, (why would you need a network only when its raining?) but from a heuristic perspective it allows a user to trace the layers of contingency between social circumstances, and pervasive technologies, to expand forms of assembly and ultimately make mediators of constituents that would otherwise be intermediaries. While it is beyond the scope of this short paper to explore the spectrum of relevant work in detail, the reader is referred to a number of tactical media practices useful to the study of mobile publics such as work across Locative Media, 'Hactivism', forms of data sonification and data visualisation, and critical Net-Art. These propose oblique ways of critiquing, imagining and disassembling the mobile public in the character of the techniques and apparatuses that came to structure it.

PARTIALLY BURIED UNIVERSITY

Karen O'Rourke

Robert Smithson realized one of his first works of Land Art at Kent, Ohio in January 1970. *Partially Buried Woodshed* (1970) was an example of the process he called "entropy made visible". At the time, Smithson said he had always wanted to bury a building. For my part, I have always wanted to unearth a Smithson.

Fig 2. Partially Buried University, 3D interactive application, 2010. Karen O'Rourke, production: CITU.

Fig 3. Fig. 1. Site of Robert Smithson's *Partially Buried Woodshed* (1970), photograph: Karen O'Rourke (2005).

Robert Smithson realized one of his first works of Land Art at Kent, Ohio in January 1970. *Partially Buried Woodshed* (1970) was an example of the process he called entropy. At the time, Smithson said he had always wanted to bury a building. For my part, I have always wanted to unearth a Smithson.

The Centre Saint Charles has a problem with rain water collecting on the roof and infiltrating the lecture hall just below. Inspired by two of Smithson's projects, "Partially Buried University" involves creating a garden on the roof terrace to absorb the residual water, reduce our carbon footprint and contribute to sustainable development. Since the roof was never intended to support the weight of growing trees and shrubs, it is likely that at some point it will collapse. The garden may then develop on its own, with weeds springing up throughout the building.

A 3-D model of the roof was built, simulating weather conditions and plant growth, thanks to models developed by engineers and scientists at the ECP-INRIA.(i) The visitor stands in front of a 3-D VR projection of the building, on the second floor overlooking the roof which has been made into a garden. She chooses a seed, putting it in a basket, then moves through the garden to plant it. After a number of people have sown poplars, cypresses, pines, maples and chestnut trees, the garden grows quickly, the roof just may give way and visitors suddenly find themselves climbing over rubble in the lecture hall below.

I will document the creation of *Partially Buried University* from preliminary research on Smithson's conception of entropy, and the public reception of one of his earthworks, to the realization involving artists, scientists and developers.(ii)

Partially Buried Woodshed

On January 22, 1970, Robert Smithson "partially buried" a woodshed by having twenty backhoe loads of soil dumped on it until the central beam cracked. Usually artists and theoreticians are concerned with the genesis of the art work. How did it come into being? From his interest in entropy and what he called "the dialectical landscape", Robert Smithson focused on process, the long-term and medium-term evolution of sites before and after the artist's intervention.

Smithson had been invited to spend a week as artist-in-residence at Kent State University by the organizers of the Creative Arts Festival. Self-taught, well known in avant-garde circles, shown in Europe ("When attitudes become form", 1969), published in *Artforum* and *Arts Magazine*, he had begun to realize his first earthworks in brownfield sites. On the Kent campus, he intended to pour mud down a slope as he had done with asphalt a few months earlier in Rome. Yet that winter in northern Ohio the ground was frozen solid: there was no way he could pour anything. Suffering from the flu, the artist was ready to return to New York. The students gathered around him at Professor Brinsley Tyrrell's house were not willing to see him go so soon: What else could he do? Upon reflection, he mentioned the idea of burying a building.(iii)

In an old farm the university had just bought at the far edge of campus, one of the students spotted an abandoned woodshed, filled with dirt, gravel and firewood. While the artist made sketches, the teacher and the students spent the day carting away most of the wood. A local contractor was hired to move twenty bucketloads of earth from another site on campus and pile them on the shed. According to a witness, "the earth was put on scoop by scoop, like applying paint with a brush".(iv) When the center beam cracked, the work was completed: it announced the beginning of the process of entropy. Smithson took snapshots with an instamatic camera. The local newspaper ran the headline "It's a Mud Mud Mud World".(v)

Partially Buried Woodshed was one of his first works on a large scale in the landscape. On January 22 he wrote a deed, giving the structure a title and a monetary value (it was Dwan, the artist's New York gallery, who came up with the price). He donated it to the university to prevent it from being bulldozed. "It was given a \$10,000 value because if we were going to try to preserve this thing, then we could argue money," said Brinsley Tyrrell, "The money thing was all a game...to convey its importance to people to whom you couldn't talk about aesthetics."(vi)

Thus began the slow decline of the woodshed, which gradually lost its logs, roof, walls, as the work was gaining notoriety. Estimated at ten thousand dollars at the time of its completion, it was worth two hundred and fifty thousand dollars at its demise fourteen years later. Today the object itself no longer exists, while the work has become legendary. Its bibliography contains dozens of titles.

In April Smithson was in Utah to build *Spiral Jetty* at Rozel Point on the shores of the Great Salt Lake. At about the same time, Kent State University was the scene of protest against the American invasion of Cambodia. The Ohio National Guard was called in. On May 4, guardsmen opened fire on demonstrators, killing four students and wounding nine others. The campus was evacuated, twenty-five students arrested. Some time after the university was closed, on the lintel of the shed appeared a graffiti painted in large white letters: "May 4 Kent 70". As Nancy Holt remarked later, "the students obviously recognized the parallel. Piling the earth until the central beam cracked, as though...the whole country were cracking. It was the end of one society and the beginning of the next." (vii). It certainly divided Americans into

two camps, the peaceniks and the war mongers. Kent State was thought by many to be the last great nationwide protest, the swan song of sixties' era student revolts, paving the way for Ronald Reagan's "conservative revolution" ten years later.

On July 20, 1973 Smithson was killed in a plane crash in Texas while preparing his project *Amarillo Ramp*. Although he had specified when he made the work that he wanted it to be allowed "to go back to the land", his widow, Nancy Holt, considered it an important work and petitioned for it to be preserved, and maintained.

In the years following the killings, Kent State's reputation was tarnished. Eager to attract students and alumni donors, the University administration invested in sports facilities. Oblivious of the work's growing importance, Kent State President Glenn Olds asked the university architect to prepare a project for enhancing the campus which would involve the demolition of the woodshed. It now stood near the new entrance to campus, on the way to the football field. To make matters worse, in March, 1975 during spring break, an arsonist set fire to the shed. The left side was destroyed, while the right side, where the earth had been piled up, was spared. This gave university officials added reason to demolish the entire structure: it was not the original, they argued, it was dangerous (visitors could be injured by the debris), it was ugly. A group of art professors objected. In the contemporary art world, *Partially Buried Woodshed* had become an object of pilgrimage: visitors came from afar to admire one of the earliest works of "Land Art". The University Arts Commission voted to preserve the work. After much negotiation, a compromise was reached: the shed remained, but the gardeners who maintained the campus were allowed to cart off debris that fell on the ground. Later the university would plant a grove of conifers around it, a barricade meant to hide the view of the "eyesore" from the road.

Visiting Kent State in 2003 I was struck by the beauty of the spot where Smithson had caused a chain of events nobody could have foreseen.[fig. 1] The process continues even today. Nancy Holt believes that it is characteristic of works of art to provoke a cascade of effects: "Works of art tend to be focal points and centers of energy that other people spin off of, and that's because works of art have no other reason for existence. They are not there for any functional reason: so they get right to the heart of things."(viii). For some today (like Dorothy Shinn), Smithson's work continues to live its life, while others, including Brinsley Tyrrell, believe that beyond a certain point the art work no longer exists: for them the site is a ruin with only archaeological value.

Partially Buried University

At first sight *Partially Buried University* (fig. 2] has little in common with its namesake. It was designed in the framework of the project Terra Numerica which developed "new tools to model the 3D city and explore new forms of urban representation". Whereas the Smithson work was experimental, more or less improvised to fit the situation, my project was more of a top-down, highly planned affair that took two years to conceive and several months to model. Smithson was inventing an art form he called "earth-works", I was interested in imagining artistic uses for technologies developed for the military and industry.

The concept of "competitive cluster" (pôles de compétitivité) is part of an industrial policy launched by the French Interministerial Committee for Planning and Development (CIADT) in 2004 to increase

France's capacity for innovation. It aims to foster an active partnership between industry, research centers and training organizations from both the public and private sectors in a strategy "designed to create synergies around innovative projects conducted jointly in the perspective of one or more markets." Led by Thalès, Terra Numerica mobilized seventeen partner organizations (all members of the cluster Cap Digital) for four years to represent the large urban areas: "urban heritage in 3D for the benefit of sustainable cities."

The context is that of a large, "top down" project driven and supported by the governmental bodies to increase the attractiveness and visibility of France in the field of information technology and communication. As a member of Cap Digital, the CITU laboratory focused on scenarios using augmented reality and virtual reality. A 3D application was produced by the CITU with the help of partners at the ECP-INRIA.

In my scenario, the visitor stands on the first floor of the Centre Saint Charles. She can move around the area on the terrace set aside for the garden, visit the rooms and corridors that overlook the terrace, move down one floor to the lecture hall, move up to classrooms on the higher floors. At the entrance to the terrace, a shelf contains several varieties of seeds for her to plant. After choosing one, she must move around to place the plant where it will begin to grow. As the number and size of the plants increase, the terrace becomes fragile and collapses into the lecture hall below.

For Smithson, entropy meant not only the deterioration of order, but more importantly, "the clash of uncoordinated orders".(vii) He told an interviewer "entropy contradicts the usual notion of a mechanistic world view. In other words it's a condition that's irreversible, it's a condition that's moving towards a gradual equilibrium.... Perhaps a nice succinct definition of entropy would be Humpty Dumpty. Like Humpty Dumpty sat on a wall, Humpty Dumpty had a great fall, all the king's horses and all the king's men couldn't put Humpty Dumpty back together again."(x)

Yet the action of entropy over time is contradicted by other processes. "Scientists have long been baffled by the existence of spontaneous order in the universe." writes mathematician Steven Strogatz. "The laws of thermodynamics seem to dictate the opposite, that nature should inexorably degenerate toward a state of greater disorder, greater entropy. Yet all around us we see magnificent structures -- galaxies, cells, ecosystems, human beings -- that have somehow managed to assemble themselves. This enigma bedevils all of science today. Only in a few situations do we have a clear understanding of how order arises on its own."(xi)

In *Partially Buried University* the viewer can see a projection in time (accelerated): the evolution of the garden, the collapse of the terrace, the invasion of the biosphere. The whole process has been greatly simplified, but users can continue to plant trees even after the collapse. The idea of collectively maintaining a garden on the terrace above the lecture hall to absorb the excess water could provide a functional solution to an architectural problem. The process creates a tension that must be taken into account, to ensure perhaps that the garden does not collapse. I would like to maintain the tension between the work of "entropy", the possible collapse of the roof, which would disrupt the course of events, as breaking the center beam of the woodshed did in Kent, and the agency of users (humans or plants) who might take advantage of the breach to build something new. As Smithson's work seemed to symbolically represent the rift in American culture of the seventies, so *Partially Buried University* could also refer obliquely to the French university strike in the spring of 2009.

I would like the final work to maintain this tension. What do we want to do after all? Plant a garden? Bury a university? And if being "ecologically correct" meant cutting off the branch on which we are seated? Others may argue that the "invasion" of the Centre Saint Charles by "weeds" ("vagabonds" as

Gilles Clément calls them) is the best-case scenario. In ecology, entropy is a measure of biodiversity. By introducing plants "foreign" to the terrace, we could contribute to this diversity.

The project should reveal the dramatic tension between entropy and organization, between the act of an artist "demiurge" and the inhabitants of the Centre who live with the consequences. They may want the artwork to be removed (and the roof rebuilt), but they might also take advantage of its action to create something else. This is not necessarily in the lecture hall, as I suggest in the prototype, but if the roof (or part of the roof) collapses, that's where we fall. The result does not depend entirely on the growth of vegetation, human users could develop improvised architectures, transform the lecture hall into a duplex, add a spiral staircase, a skylight.

LUDIC LISTENING: SOUND ART IN VIDEO GAME DESIGN

Aaron Oldenburg

This paper will briefly discuss the history of sonic experimentation in digital game design, and describe one of a series of games the author is in the process of creating that directly address ideas in sound art theory. These projects focus on the world of audio with the intention of distancing video games from the rational and concrete. Video games in turn facilitate the exploration of relatively new paths in sound art.

This paper describes several experiments in audio-based game design that attempt to expand the expressive vocabulary of games, briefly discussing the histories and theories of sound art and video game design while outlining their potential to merge. These experiments probe what appears to be under-explored territory in audio games: although music-based play has been popular for some time, dating as far back as Mozart's musical dice game, [3] other forms of sound are relatively under-explored as the basis of game mechanics. This paper assesses the history of audio-based digital games, particularly the genre of music games, examining their limitations while drawing attention to areas of current and future experimentation. The author is in the process of creating a series of short games that explore new forms of audio-based game design, and will discuss one that involves voice-activated visual echolocation in an evasive three-dimensional sonic landscape.

The majority of audio-based digital games are musical and are comprised of the following two major categories: those that build gameplay around pre-existing musical compositions and those that generate dynamic music as a result of player action. In many music video games, the challenge that players face is to hit specific buttons in time with the beat of pre-recorded music. By contrast, the shooting game *Rez* allows players to compose music indirectly, by playing notes that are generated by the player's firing pattern. [5] Much interactive music software falls outside of games and into the more general category of "toys," as they have no set goals or obstacles. Often the player's only given objective is to compose music through experiment and play. Game or interactive toy-based generative compositions are not without constraints, however, as designers often restrict players to a certain set of notes to prevent them from creating music that is too dissonant and in some cases even alter the player's feedback to fit a pre-conceived rhythm.

Broader definitions of music, such as those proposed by John Cage, have not been widely explored in music-based digital games. Independent and experimental game designers, however, have explored other forms of sound-based game design. Eddo Stern's "Darkgame" installation relies on visual sensory deprivation, focusing in part on the side-effect of heightening other senses such as hearing. In experimental game design competitions, it is a popular challenge to create non-visual gameplay that requires the player to navigate by sound. Although three-dimensional first-person shooters have always relied on audio cues to alert players to the offscreen presence of enemies, the aforementioned games explore new ways to use audio as a way to augment or replace visual navigation.

Sonic art theorist Seth Kim-Cohen argues for a conceptual sound art that is not based on what is heard, "but in the elsewhere/elsewhen engagement with ideas, conventions and preoccupations." [4] Just as

the visual arts have explored the verbal and written communication of ideas over the retinal, he believes that sonic arts can move beyond the sensory. "Hear, Hear," an artwork created by Papermen at Eye-beam, New York, in 2011, is a silent kinetic sculptural representation of the collecting of vibrations by the ear and processing by the brain. It is a silently moving sculpture that nonetheless sparks a cognitive engagement with the processes of hearing. Are there ways that games can represent sound without reproducing it? Games are simulations, or, as Salen & Zimmerman put it, "procedural representations of reality." [6] It is interesting to note that most representations in game worlds, whether they be of death, conflict, conversation, are all simulated, yet sound is almost always reproduced (like visuals). An important area to explore, it would seem, would be simulation of sound through gameplay: having the player perform actions that are representative of the physical and cognitive aspects of hearing, listening and sounding.

What aspects of audio hold potential for game-based simulation? Consider the following descriptions of sounds in the context of actions, environments and visual representations in video games. David Toop compares sound's properties to those of "perfume or smoke," stating that "sound's boundaries lack clarity, spreading in the air as they do or arriving from hidden places." [7] He points out that sound "implies some degree of insubstantiality and uncertainty, some potential for illusion or deception, some ambiguity of absence or presence," and that, "Through sound, the boundaries of the physical world are questioned, even threatened or undone by instability." [7] Sound also has the "ability to stretch across the cut, to meld continuously from one 'object' or entity to another." [2] Sound always arrives at our ears blended, like shadows. [1] Typical games, by contrast, are often about the manipulation of distinct objects with logical boundaries. Games are often, however, about discovering alternate universes, and so contain the potential to allow players to explore worlds with fluid boundaries and objects that blend or arrive with ambiguous origins, like sound.

Optic Echo is a game created for mobile devices with the intention of representing visuals as sound is heard. Walls in the 3D environment are represented not as solid points in space but as particles flying toward the player "from hidden places." Visualization of the player's environment and non-player characters is migratory, ephemeral, like sound. Gameplay references echolocation: the player makes a constant noise (for example, with his or her voice) into the microphone and the game uses the volume of this sound to visually render the walls of the 3D environment, as if the particles were noise echoing off of the walls. The location of solid objects, like the origin of sound, must be inferred from the "optic echo's" movement. The manner in which the visuals were created to resemble sound was inspired by a quote from Frances Dyson in *Sounding New Media*:

like the fire, sound is always coming into and going out of existence, evading the continuous presence that metaphysics requires; like the fire also, sound is heard and felt simultaneously, dissolving subject and object, interior and exterior. Like the river, sound cannot be called 'the same' since it changes at every point in its movement through a space; yet like 'Soul,' it does not strictly belong to the object. Nor can sound's source and ending be defined. [1]

This was an attempt to mimic audio through another sense, a step toward simulating audio through gameplay.

Humans cognitively approach sound in ways that we do not engage with our other senses. Could it be that in games, navigating a 3D spatial tactile world is not the best way to move? How about forward and backward through the time of a sound? What choices could the player make as they move, what obstacles overcome? Studying audio gives game designers new ways to construct (and deconstruct)

space and action. Conversely, the 3D spatio-centric worlds of video games give artists who work with audio a space where they can explore goal and conflict-based compositional techniques, giving their audiences the potential to engage and procedurally explore the processes of hearing and listening.

BODIES, INTERACTIVITY AND TECHNICITY IN MEDIA ART

ANDREIA OLIVEIRA

This paper addresses the *degrees of interactivity* produced with and within an artwork. The act of experiencing an artwork shows that any experience is made up of relations of intensity within processes of interactivity between bodies and milieus. These ideas are based on the philosophical writings of Baruch Spinoza, Gilbert Simondon and Gilles Deleuze and are applied to the field of interactive art.

Introduction

This writing is inspired by Spinoza's question—*What can a body do?*—and by his answer—*we never know what a body can do*—until the encounter, and then, what it *can* do depends on the intensity of the encounter and the body's capacity of affecting and being affected. Spinoza's question is the foundation of this paper and it will be concurrently problematized in three different fields of knowledge: Arts, Philosophy, and Psychology. Also, we avoid paradoxical extremes, e.g. natural and artificial, art and life, analog and digital, human and technological, real and virtual, etc which can be reconciled by creating paradigms that propose novel conceptions of what constitutes bodies, environments, artworks and technology.

It begins by asking the question *What can a body do?* and proceeds to ask *How much can a body do?* in the encounter, in our case, with an artwork. In this encounter with the artwork, the relations of affects and affections between the artwork/artist's/spectator's bodies and the milieu happen as an interactive process. Any experience implies interactivity but our interest lies in how this interactivity happens: What are its modes of production? How are bodies themselves affected? What are the nuances of such experience? Thus, our aim is to investigate the ontology of experiencing the artwork, or better yet, in the artwork with its processes of interactivity, herein referred to as *degrees of interactivity*. [1] The artworks as outcomes of a processual and systemic thought which does not dissociate the artwork-human-milieu, and directed to the intensities of the encounter. So, the question *How much can the body do?* in the encounter with the artwork is posed in terms of *degrees of interactivity* between bodies and milieus associated in intensive experience.

The body referred to here includes not only the human but the non-human as well—animal, technological, immaterial—formed by the speed or slowness of matter-taking-form. According to Spinoza, “we have conceived an individual as composed of several individuals of diverse natures, other in respect of motion and rest, speed and slowness”. [2] To imagine the body differently we will need to cast off anthropocentric and transcendental positions and consider its spatial extension, potentials, intensities and movement in new ways. The question of the body will be examined from a Spinozist perspective based on the idea of parallelism between body and soul and the concept of the intensive immanent body; from Deleuze and Guatarri we will use the concept of the body without organs; and from Simondon the information body.

The body formed by a technology—thinking, walking, seeing, typing—its nature is essentially artificial. A body is not dualistic as it integrates dichotomies: it is analogue and digital, human and machinic, natural and artificial, perceptive and imperceptive, body and soul, matter and form. It must be stressed that the

body as matter-taking-form only exists in the presence of other bodies and belongs to the associated milieu by which it was created and within which it was created. Artwork, human, animal, machine, landscape, idea-body... bodies of flesh, blood, computer chips, images, sounds, waves, frequencies, affects, signs... bodies not bounded by skin, canvas, walls, or screens... extensive bodies in milieus where they become associated as intensive relations.

Thus, bodies are always in relation with each other, associated to the milieu to which they belong. This paper emerges from concerns and observations about how the artwork is constituted: the artwork belongs to the associated milieu; the artwork is a techno-aesthetic object produced by technology and its entrained technicities; and the artwork can only be understood through the artwork-human-milieu system.

Associated Milieu

In this sense, we propose a relational perceptual causal chain that underlies a machinic experiential interpretation of the interactive process where viewers become one with the artwork in the experiential milieu that will come to be seen as the exhibition spacetime.[3] We seek to consider the experiential milieu itself as the conditioning environment for the subjective entity that constitutes the event and locate it at the junction of the site of exhibition and the viewer function where the virtual and the actual coincide and become pure experience. In order to do that what we need is not a perceptual causal chain per se but a remapping of the experiential milieu where viewers become one with the artwork-world within which they are enveloped.

The milieu is normally understood as the ensemble of external conditions within which a living being lives and develops or as the assemblage of material objects and physical circumstances which surround and influence an organism. Conceptually, "milieu" can also be seen as an environment in the widest ecological sense of the term, i.e. as the locus of the dynamic interaction of all the factors and mechanisms that participate in the sustenance of an ecosystem.

The concept of the associated milieu, conceived by French philosopher Gilbert Simondon in his book *Du mode d'existence des objets techniques* (1989), is a useful model to analyze the co-arising relationships that take place between an artwork and its conditioning environment. The descriptive term "associated" when applied to describe milieu refers to a specific mapping of an ensemble made up of constitutive elements (which can be sub-ensembles) and conditioning environmental modalities which come together to create a concretized individuation through the ongoing exchanges of energy that take place within that specific milieu. [4]

The milieu allows for a reciprocal relational causality to take place between the elements so that we may conceive of spacetime as the immanent plane from which the subject and object arise. The associated milieu sustains, unites and brings together bodies: it is not a stage upon which a scene unfolds, or a play where only the actors perform, or a canvas upon which the pigments run into each other, or a manuscript where the words follow each other in sequence. The milieu is the setting and environment of concretion, of aggregation, where things condition each other in order to form something which in turn, simultaneously, allows these very same things to take form themselves. In other words, the milieu allows for a non-static, dynamic form as an event of taking-form as experience.

The milieu crosses through bodies, simultaneously existing within the body and outside of it like the air which one breathes, or the water that permeates our body, or the earth that nurtures and nourishes us. To think of the milieu is to think of the production of the body proper, its modes of functioning, and its pre-established connections and relations. In this way, the milieu is active and defines itself as a source of energies, perceptions and actions.

From these preliminary ideas about milieu, it appears that the artwork is produced from the relations between bodies and milieus, mediated by *technologies of creation* and their technicities, where relations are expressed as variable intensities of interactivity, i.e. as *degrees of interactivity*. These degrees are nuances of the act of experiencing: mixtures, attractions, embodiments and perceptions. Various and concurrent movements, mixing within the milieu, attracting each other, incorporating fragments of bodies, perceiving (themselves) as body and associated milieu as ephemeral landscapes.

Degrees of Interactivity

Mixtures are inevitable; they are voluntary and involuntary affections between bodies and associated milieus; hybrid bodies belonging to the milieu and keen to experience themselves in different ways. To understand the pragmatics of bodies, it is imperative that we understand the immanent relations of bodies. Plato's, Spinoza's, Deleuze's and Simondon's ideas of immanence produce differentiated bodies. In Plato and Aristotle, the transcendent and immanent planes oppose each other, as do body and soul, where the supremacy of the soul prevails. Spinoza brings together transcendence and immanence, as well as body and soul, as parallel relations. The relations between bodies and milieus are immanent and intensive, bodies and souls being relations of speed and slowness. We are equal in terms of attributes, and singular in terms of modes of existence.

Their Ethics are based on what a body is capable of doing, and the positive encounters which potentialize it. In Simondon and Deleuze, bodies and milieus mutually adapt to and create each other in the act of experiencing. Bodies, as relations/gestures of individuation, are no longer subordinate to Aristotelian substance mentioned earlier; being, as the union of the individual and the milieu, is no longer Spinoza's Divine Being; mixtures address the interdependent relations between bodies and milieus. They are mundane signs inhabiting mixtures. These paradoxal mundane signs can lead us to intensive relations with the milieu, exposing bodies to contagion; or they can leave us with empty action-reactions, abandoning the body to suffer the effects without knowing the causes.

Attractions move bodies. Bodies touch each other through the associated milieu where they come together complicitly. Desire expands bodies throughout the milieu, and keeps them connected. We are dealing with an animal art that shows us the potential of the milieu and the affects bodies resulting from the animal behavior of feeling the vibrations of other bodies of through the associated milieu. "All art begins with the animal, for it is the animal, and not machines, minds, or subjects, that carve territories and bodies simultaneously: minds, machines, subjects are themselves the artistic products of this coupling of bodies and milieus". [5] Animals can only catch their prey when part of their body and part of their prey are mixed. When part of the artwork is already part of the spectator's body, we enter the artwork with one body and leave it with another one. Animal-becomings make us discover non-human bodies.

We fall back on affects of relations, where the agent-causes of other bodies on our own are known, where affects are felt as variations of the force of existence of the soul and of the potential of the body

to act. “For, in proportion as the body is capable of being affected in a greater variety of ways, and of affecting external bodies in a great number of ways, so much the more is the mind capable of thinking”. [6] In the attractions, it is understood that bodies produce affects—Art being a block of affects and percepts. [7] When attracted, one is captured by the amorous signs that deceive and create fictions, either making us prisoners of the illusions of representation, searching for origins and truths, or releasing us to confabulations, lies and invented realities.

Embodiments are visceral once we give body to that which is lived. Causes are not only known, but also created; propositions, objects, experiences are produced by means of technologies. The act of embodying life is technological, in that what is natural is effected by the artificial. Appropriate technologies are needed to give form, or better yet, for matter-taking-form. Artists use/invent technologies to compose the elements affecting them in order to arrive at the technicities of the artwork.

In this sense, Simondon rescues the relation between man and technics by re-defining human existence in terms of the technical reality that surrounds it. Simondon developed the concept of technicity in terms of open machines and conceived new environments for their unfolding in terms of the associated milieu which allows the inter-dependent co-arising of the technical object, creator and environment into an event.

Through the techno-aesthetic object, art liberates technics and techniques from their technological and cultural contexts in order to surpass their initial function and purpose as well as promote other ways of feeling and thinking. It must be emphasized that this direction consists of a political and ethical position (and not a moral stance) that provides us with the means of thinking our existence in terms of the technical reality that surrounds us.

Technicities belong to bodies; they are the expressive qualities that arise from the composition and organizations of their elements as individual ways of composing: the singing of a bird, the coloration of a plant, the functionality of a machine, the expressiveness of an artwork, the gestures of a dancer... Technicities move within the technical and aesthetic dimensions of techno-aesthetic objects, centering us on that which happens within matter and form. “Matter is thus defined in terms of a *form-taking activity* immanent to the event of taking-form.” [8]

Each element draws out implicit forms which are manifested in the techno-aesthetic operations which also determines them. The aim is to understand that which is produced in the experience, in the artwork, artist, spectator, art gallery—with its materials, elements and implicit forms. From sensuous signs, we embody that which tells us about the material qualities and guides us to the immaterial in Art. Signs bring on degrees of interactivity which create information that disrupts the artwork-human-milieu system while internal resonances are produced. Thus, tendencies and attractions become embodiments.

(Im)perceptions are landscapes of creations/actions to be lived. They are actions resulting from embodiments, i.e. they are the effects of mixtures, attractions and embodiments. In order for us to live, we need landscapes to shelter our bodies and souls. Art goes beyond explaining the creation of ephemeral landscapes, it brings us to create unusual landscapes. The singularity of landscapes consists of making visible that which is invisible and allows us to arrive at the imperceptible in perception, the immaterial in the material, the technicities in technologies. It must be stressed that the body perceives before the soul can contemplate; the body perceives not only with the sense organs but also with the affects which inhabit it. Perceptions take place between the perceiver and that which is perceived by means of dynamic forms. “Art brings back out the fact that all form is necessarily *dynamic form*”. [9] For this reason, the

artwork can only be understood through the intrinsic and extrinsic dynamics of the meta-stable system of the artwork-human-milieu. This system encompasses an internal resonance herein understood as interactivity. Because the system is meta-stable, it is subject to the problematizing caused by information, which triggers new individuations. [10]

The function of Art is to produce information, to cause alienations so that landscape-simulacra can arise. Landscapes are created through the oscillation between panoramas—prisoners of false impressions and mimetic representations—and simulacra formed in the encounter of dissimilarities in order to produce invented realities: invention is the highest degree of interactivity. Signs in Art give access to the information that produces phase changes in the artwork-human-milieu system: the sign in Art is not the perfection of the sign. It is paradoxical as any other—it closes up when it falls apart in the dissolution of the form, where it can reach the extremes of schizophrenic landscapes; it opens up when absorbing the immaterial dimension of life though the perception in the perception, where landscapes full of different signs are created.

Conclusion

Mixtures in mundane signs, attractions in amorous signs, embodiments in sensuous signs, perceptions in signs in Art: [11] *degrees of interactivity* of an experience. For an experience to be intensive, the sign must remain open to its dynamic and associative processes as it is not a particular sign or element but the associations of signs and elements which move through all *degrees of interactivity*. In this sense, the problem the paper considers is the dynamics of *degrees of interactivity* in the experience of bodies—artwork, artist/spectator, machine, ideas—and their associated milieus, or better, the process of interactivity in art.

We seek to problematize questions of interactivity in order to open pathways to think the techno-aesthetic art object in terms of real interactivity and not simply responsiveness: What constitutes interactivity? What is the role of the spectator/participant? What is the role of technology as the mediating agent? What kind of bodies, milieus, space-times result from the interactive techno-aesthetic object? What are the ontological implications of these techno-aesthetic considerations? How may we think of interactivity in the humanities through art experience?

When researching interactivity in the Arts, it is inevitable not to take the problem to the field of interactive art. Interactive artworks take place and are modified during the artist/spectator/artwork/milieu experience; as they are fundamentally relational, they break down the frame and require participation. Their immaterial potential will be realized in the relational mode in which they operate by acting as a mechanical translator of content and representations, or as a machinic transducer of information. “We understand transduction to be a physical, biological, mental, and social process through which and activity is propagated from individual to individual within a domain.” [12] By being an art of action, interactive art can instantly produce action-reactions, or the action can be the effectiveness of the techno-aesthetic operation of the artwork itself as performed by the spectators, in other words, an artwork keeps its operation open in order to allow the spectator to access its implicit forms. Interactive art presents possibilities to explain the processuality of *technologies of creation*.

Technology has its own specific modes of producing bodies which go beyond those which participate in interactive processes. In this sense, when interactivity is produced within techno-aesthetic objects, the compositional relations create novel modes of expression of what a body is and what it can

do. Therefore, the questions become: what is possible (or not) within this construction of bodies and milieus in interactive art? Where is the ethical limit which guides such productions? How much can a body endure within the proposed relations?

This paper comes to the conclusion that *processes of interactivity*, especially in interactive art, address the ethics of the body's potential to act [13] in terms of *how much can a body do?* We seek answers to how an artwork can provoke "joyful" encounters which liberate the potential to act as well as *degrees of interactivity*. The artwork itself does not *per se* exist except as the aesthetic experience with and within the artwork: it exists as an individuation of the artwork-human-milieu system. Simondon's ethics propose processual thought as a constant individuation. His philosophy of technics addresses an ontogeny of human and non-human being (individual and milieu) and is not concerned first-hand with the final configuration of things but with how they become what they are. It is thought that can support interactive art and made to be modified over time as it gathers existential amplitude in its matter-taking-form process.

Promiscuous/ethical bodies are found in the art-life experience; they are promiscuous in the act of mixing amongst themselves, and ethical in their potential to act according to the dynamics of *degrees of interactivity* within each experience.

NANOVIBRANCY: AN AUDITORY PERFORMANCE OF NANOSCALE RESONANCE

Joel Ong

Nanovibrancy explores nanoscale activity by amplifying the oscillations at the surface of a model tympanic membrane in real time. The project repurposes the AFM by extending its reach into the creation of abstract, subjective and ephemeral sound. It shifts the observation of the miniscule from scientific eye to artistic ear, amplifying the resonance of reality and imagination through a confluence of nano and human scale listening.

Introduction

This paper describes key concepts and processes behind Nanovibrancy, a sound performance installation that utilizes the atomic force microscope (AFM) as a listening device to record and amplify vibrations on the surface of a membrane. It rests the probe in the centre of a silk membrane that functions as a model for tympanic listening. In so doing, the AFM does not deliver a visual representation of the membrane insofar as it is tasked to provide an image of it; but more to determine its process over time and stretch the image into an evolving and ephemeral soundscape.

The project aims to subvert the premise of visual imagery in the current climate of nano-scientific observation through audile, subjective and ephemeral data derived from the AFM scans in real time. It is also site-specific in that it creates an immersive sonic environment fusing the nano-scale resonance of vibratory matter and the human-scale acoustical environment of the gallery space. Nanovibrancy was presented as a durational performance-installation at the John Curtin Gallery in July 2011. (Figure 1)

While the AFM is still an image-creating machine (albeit through complex but arbitrary algorithms), it removes the distance required by the focusing lenses of light-based microscopes and actually contacts the sample's surface as a way to gain atomic resolution. This emphasis on touch as the operant sense for nanoscale perception therefore allows a reordering of the scientific observation strategies commonly associated with microscopy. In addition, it also offers the chance for an artistic, poetic representation of the nanoscale environment. Since the sample's vibrations are highly influenced by environmental factors like ambient noise, air flow, temperature and humidity, this process reflects a vibrancy and agency that is not only centered on the sample, but also in its dynamic position within the environment.

Sidelining Ocularity

The invention of the Scanning Probe Microscope (SPM) and its offshoots the Scanning Tunneling Microscope in 1982 and the AFM in 1986 by Gerd Binnig and Heini Rohrer (Binnig and Rohrer, 1986) revealed that to image high-resolution samples at the smallest scale possible, light had become obsolete.

While conventional optical approaches reflected light off the sample through a series of lenses, these devices worked by directly interacting with and touching its surface. The resolution possible was now beyond the effective wavelength of light, inaugurating a range of microscopes that could see into the nanoscale, but ironically were 'blind'.

This invention of the SPM technique signaled a paradigm shift that Peter Galison (2006) refers to as replacing visual ontology with an action or intervention. In so doing, the visual output of the microscope becomes connected to this ability to contact and change, becoming sidelined as a sensory accomplice in the creation and manipulation of nanostructures. Thus the image ceases to be an end in itself - even more than just highly publicized and highly seductive icons of a new science, they implicate the objects they depict as malleable and kinetic.

In Michel Certeau's 'Walking in the City', he describes the vertiginous experience of one observing the street from the top of the World Trade Centre as being created in distance and removal from the "grasp of the city", and later the collective experience at street-level of pedestrians as a "swarming mass (that) is an innumerable collection of singularities" (Certeau, p155). He describes the way in which sight functions as a voyeuristic activity that immobilizes the mass of individuals from a distanced perspective. To

walk the streets of the city therefore warrants an Icarian fall - to place oneself under the threshold of visibility 'down below' and to be immersed as a walker, a Wandersmänner, charting the trajectories of movements as a subjective and durational activity.

Salome Vogelín adds that the 'godlike' view from the tower results in total, objective knowledge whereas the activity of the man on the street is not receptive, but exploratory:

"De Certeau's city on the ground level is created by these blind practitioners, who by association hear rather than see its text, 'make use of space that cannot be seen' and produce with their footsteps the city as a heard phenomenon." (Vogelin 2010, p92; Certeau quoted in Vogelín 2010)

In the same way optical methods of observation and image creation that rely on focal distance are sidelined in favour of the physical exploration of the cantilever on and in the membrane. Nanovibrancy relies on this performativity of the membrane as process, replacing the static visual ontology of the sample with an auditory documentation of its material agency. The position of the listener in this case is explored between his/her bodily presence within the soundscape and the perspectival distance arising from the representation and mediation of nanoscale audition.

Leaning on the surface of a Membrane

Nanovibrancy is as much a performance as it is a passive observation. Any sound that is heard relies on the inherent agency of the membrane, rather than on a form of composed or pre-determined activity. This inclination to inflict and impose oneself on the activity of the membrane is both an artistic and scientific tension. Since nanotechnology offer the capabilities to manipulate atomic particles, the impetus to 'do' something rather than just passively observe matches the expectations of sub-molecular rearrangements, attaching and removing individual atoms, or even leaving marks on the surface as experimentally useful procedures.

The sounding of a membrane that 'amplifies' rather than 'affects' it emphasizes the sounds that are already present in it. Jane Bennett refers to the "capacity of things . . . not only to impede or block the will and designs of humans but also to act as quasi agents or forces with trajectories, propensities, or tendencies of their own" (Bennett 2010, viii), echoing Bruno Latour's definition of the "actant" which is a source of action which has an individual efficacy and the ability to modify another entity. The membrane is seen, and heard, as an actant, with its own agency and efficacy.

But as a membrane - a flap of freely suspended 'skin'; it is implicated as an active listener of its environment, extending the repository of internal sound to include its acoustic environment. Scanning the membrane reveals its internal structural mechanisms and the inter-atomic forces at its surface; it also reveals its exteriority within the medium of air and the vibrations it experiences as a result of gaseous atomic activity. The membrane thus becomes a dynamic actant whose agency is reflected in a state of becoming within its external acoustic milieu. Gaston Bachelard argues:

In its energetic folding the atom is becoming as much as it is being, motion as much as it is object (Bachelard quoted in Andrews 1992)

Similarly, the membrane as dynamic process literally and metaphorically usurps a visualist definition of the 'object' - it does not offer a static depiction of the sample. Instead, it stretches the effective image

into the observation of a process – of the object as a vibrant participant within its environment occupying a transitory middle ground “between potential and actual” (Andrews 1992).

In Nanovibrancy, the listener is brought into the space of the nano-cosm through a sharing of the acoustic environment of the membrane. Listening to the membrane thus creates a dynamic continuum that connects the listener and the object in an ensuing relationship within these energetic oscillations. The perception of sound is determined by the physicality of all the components that conduct it. Therefore, the physiological hearing activity, its model through the silk membrane and AFM assembly in Nanovibrancy explore their “energetic unfolding” within the acoustic environment, becoming indicative of the continuum of vibrations through the membrane, air and listening bodies. As Salome Vogelín describes:

Listening produces me as a dynamic subjectivity intertwined with the dynamic things that are thinging the life-world rather than in relation to a substantial and permanent vis-à-vis of a transcendental world. Any connection of myself to another thing or subject ensues in this dynamic. (Vogelín, p 94)

By extrapolation, everything present is a dynamic actant involved in the sensitivity of the membrane. This presents an interesting contrast between the reductionist ontology of the ‘atom’ and the expansion of an ecology of materials into the macro-environment where it is defined not by itself, but in its enfolding external relationships. Georges Canguilhem’s defines the milieu as “an array of decentred and mutually influential relations between an organism and its surrounding environment” (Canguilhem, quoted in Roosth 2009). By extension, the acoustic milieu therefore can be said to be made up of mutually influential assemblages of organisms and their environments within a landscape of vibratory oscillations.

The assemblage in Nanovibrancy is made up of connected things extending the vibratory continuum upward and outward into anything and everything in the environment but extends even further through the air in the room into the listening bodies.

The model of tympanic listening through a membrane implicates the physiological hearing pathway as a series of connected, conductive mechanisms all grouped in an assemblage that effects the eventual signal that is perceived, even as it is an indication of an inter-subjective phenomenon.

From the listening body, the room as the metaphor of a resonating chamber implicates its structural components as material participants rather than passive observers of the performance. Sound accentuates the physical construct of an architectural space because at certain “resonant frequencies”, the walls of a room will begin to ring, presenting every constructed space as a palpable entity with its own sonorous potential.

In Nanovibrancy the perpetuating feedback loop between the listening membrane and the gallery space becomes an aggregating mass of auditory feedback. These frequencies that arise through this process do so at the natural resonant frequencies of the architecture. Albeit, the architecture is a dynamic entity in itself, responding to change in variables like human movement, air flow, thermal flux etc.

Imaginative Listening

Sounding the membrane does not only reveal the material assemblages that bridge the listener and the object through conductive resonance; but through the cognitive activity of listening, it furnishes an imaginative proximity to the source.

Sound draws together the sounding object and the listening body in a relationship fortified by the acoustic connection of the two. Where Nanovibrancy aims to bridge the distance of scale, this is not an acoustic one but more an imaginative one. By amplifying the membrane, it presents the illusion that transplants one, blind, onto the surface of the membrane – What would the eardrum sound like if we were small enough to stand near it? (Figure 2)

In the metaphor of the nano-scopic microphone, the stimulation of “magnified” listening also presents a duality of cognitive spaces. In the first instance, the recording of nanoscale vibrations situates the context of listening within a visual causation of atoms vibrating i.e. my mind sees images of the atom in motion, the atom in the assemblage and so on because I know that this is the supposed result of the experimental setup. But in alluding to a post-perspectival space away from the inclination towards visuality, perceiving the space of the nano-cosm becomes a fundamental activity in reduced listening. It becomes an imaginative, mythological realm where the image is abstracted into its visceral, somatic and immersive soundings. In this position, I do not know, and I do not have to know what exactly constitutes these vibrations, I hear, feel and am immersed in it as a tangible, vibrant and energetic gestalt.

Nanovibrancy thrives on the imaginative experience of sound, one that emerges from sensory extension of our ears into the nanoscale. In the actual performance, the sounds that were present in the gallery space were not stylized representations of nano-activity; instead I sought to present the sounds as they were. As a result, there were often patches of silence, or low-level static sweeps that were not the most interesting sounds possible. This artistic tension in allowing the sounds to be themselves became a defining character of the performance and the developments leading up to it.

Conclusion and Further Thoughts

Nanovibrancy thus presents a site-specific installation performance that subverts the optical expectations of an objective science. Through its amplification of the minute vibrations on the membrane’s surface, it unfolds the nanoscale interactions of molecular bombardment and thermal interference as an evolving soundscape over time. This enhances the emerging rhetoric of nanoscience as being invested in the materiality of atoms and molecules and their interactions with each other, and within the broader molecular environment. With the proliferation of haptic feedback devices that provide users with more tactile control over their samples, the visual output would then become connected to this ability to contact and change, becoming more of a sensory accomplice in the creation and manipulation of nanostructures.

In its ability to reach into the nanoscale, nanoscience becomes a milestone in the creation of scientific knowledge. This potential to now see, touch and hear at such a small, yet physically grounded scale goes beyond the social constructions of art and science. And in the work of Nanovibrancy, it reveals a deeper essence that is found within the vibratory continuum existing at the nanoscale. The words ‘minute’, ‘miniscule’ and ‘infinitesimal’ that litter the discourses of nanoscience become more than imaginative sources but palpable entities; the connections we forge across scales of perspective are now

founded within the common ground of vibrant matter. Our listening ear is to be reinvigorated by knowing its place in the atomic assemblage, and our imaginative minds brought to new spaces of creative exploration through the immersion of sonic potential.

Gaston Bachelard reveals in the *Poetics of Space* that such imagination of the miniscule cannot be founded upon the logic of human-scale perception, but instead need to be subtended down the rabbit hole of abstraction and absurdity. And as *Nanovibrancy* locates itself between the spaces of material resonance and mythological imagination; the milieus of fact and fiction, the fertile grounds of imagination and reality now collide and reside in close proximity with each other.

Acknowledgements

Nanovibrancy was developed at at SymbioticA, the Centre of Excellence in Biological Arts, Anatomy and Human Biology at the University of Western Australia and has the generous support of the Ear Science Institute of Australia, the Nanochemistry Research Institute and the John Curtin Gallery at Curtin University. As most nanoart projects require the collective efforts of scientists and artists, this project could not have been possible without the infallible guidance of Ionat Zurr, Ralph James and Thomas Becker. I would also like to thank Chris Malcolm, Paul Thomas, Salome Voegelin, Rob Murano, Rob Eikleboom and all at SymbioticA.

TOUCH INTERFACES – BETWEEN HYPERREALISM AND INVISIBILITY

DAVID OSWALD

In this paper current trends in mainstream multitouch interface design are analysed. Based on a critical review of Apple's iOS Human Interface Guidelines and on experience from teaching several multitouch design seminars, recommendations for design practice and some forward-looking statements concerning hyperrealistic interface metaphors will be derived.

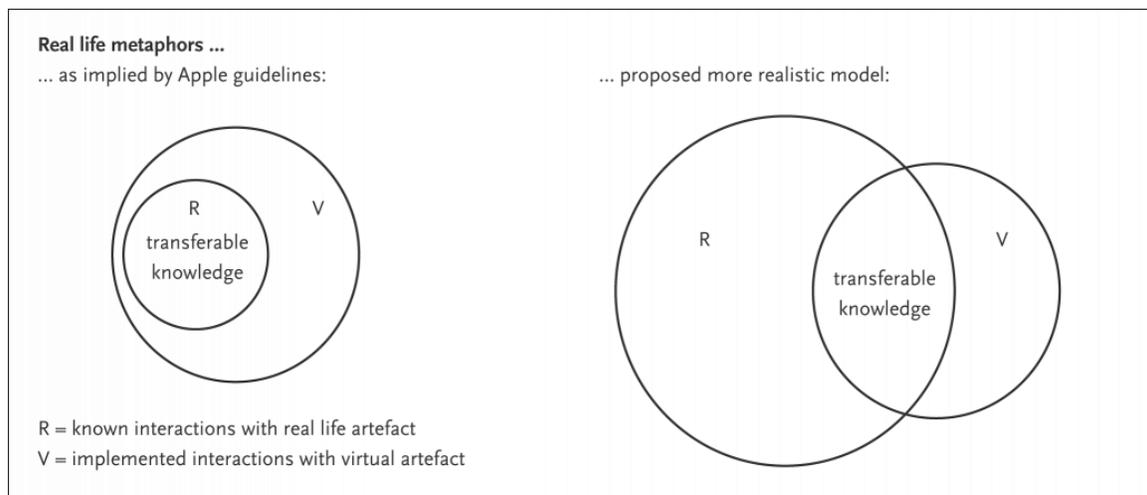

Figure 1: Knowledge that can be transferred from interaction with real life objects to interaction with metaphoric interfaces. Copyright by the author.

Introduction

Multitouch technology has existed for several years today. [1] While big multitouch tables have mostly been found in public places like exhibitions, small screen devices like multitouch smartphones have become an everyday phenomenon. In both cases the context of use has been different from the use of a desktop computer. Multitouch table systems often are designed for specific content, an individual location and fixed context of use. In contrast, smartphone applications are to be used in any context – due to mobility. With the emergence of medium sized multitouch devices like the iPad, more and more digital products, which are known from a work-related desktop context, are being redesigned for multitouch use. But just like the invention of the computer mouse was a prerequisite and an activator for the invention of graphical user interfaces and new software genres, [2] multitouch interaction is a prerequisite and activator for novel interfaces and the emergence of media formats and applications which are specific and typical for medium-sized multitouch devices.

Today two trends in multitouch interface design are already apparent: Photorealistic real live metaphors like wooden bookshelves on one hand and direct, touch-based interaction without any visible buttons or handles with content like maps on the other hand, or even sensor based interaction.

Realism and Learnability

The real-world metaphor approach has already a tradition in human-computer-interaction. The very first graphical user interfaces of the late 1970s were based on a visible real world metaphor. But due to technical limitations the visual style and the iconography of the desktop interface was quite abstract – black and white pixels only in low resolution. This relatively high level of abstraction helped to forget about the original meaning of these metaphors once the user's learning phase was left behind and the meaning of interface elements had been internalised. When seeing "menus" in a software application today, no one thinks of a restaurant's list of dishes. The idea of a restaurant menu was helpful in the early years of GUI, but today's computer users would be rather distracted or even confused by a photorealistic imitation of a restaurant menu card with "cut", "copy" and "paste" listed on it.

A second wave of more realistic real world metaphors hit the interface design discipline in the early 1990s when "interactive multimedia" became popular. Abstract and text-based interface elements like menus, buttons and drop-down-lists were replaced by the display of everyday objects in everyday environments. These were again real live metaphors – now with a higher level of detail, showing greater similarity between the real world objects and the visual representation. In spite of significant usability problems the naive realism of these interfaces was a success in so called "edutainment CD-ROM" applications. Attempts to transfer this approach to standard software (like Microsoft BOB) at this time failed completely. [3]

HYPERREALISM IN MULTITOUCH INTERFACES

Today applications on an Apple iPad again look like real objects. E-books look like real books, software calendar apps mimic paper sheets, leather covers and even chrome-plated spiral binding. Compared to 1990s multimedia the level of photorealism and the aesthetic quality are obviously superior, but the concept is the very same. And also the theory behind real-world metaphors is still the same: They should help the user understand and learn how to use virtual artefacts by transferring knowledge from real

world interaction to the computer world. In their Human Interface Guidelines for iPhone and iPad, Apple therefore recommend the use of real world metaphors as standard practice: "When virtual objects and actions in an application are metaphors for objects and actions in the real world, users quickly grasp how to use the app." [4] Addressing possible limitations of such an approach, Apple are worried only about possible shortcomings of the real-world antetype's functionality: "The most appropriate metaphors suggest a usage or experience without enforcing the limitations of the real-world object or action on which they're based. For example, people can fill software folders with much more content than would fit in a physical folder." [4] This is a quite one-sided view – only focussing on limitations of the real-world object and disregarding the limitations of the virtual object. When we see a book in the real world we exactly know what we can do with it, how we handle and navigate it and we also know what we are not able to do with it. With a photorealistic representation of a book on a screen this is different. Of course the resemblance to a book gives the user some clues how to possibly interact with the interface, but it is quite clear that the user can only interact in ways that are anticipated and implemented by the creator of the software. Probably it is possible to "flip pages". But there are several ways how to flip real books' pages – where do you have to touch the page, what kind of movement is expected? Is it possible for users to write annotations? How? Does it allow to mark pages with dog-ears – and why not? Is it possible to rip out pages?

Based on everyday experience we know how we can interact with our environment and what we can do with the objects surrounding us. Due to this everyday experience we are even able to anticipate possible uses and interactions with artefacts we have never seen or touched before, just by looking at them. [5] We immediately know how our body relates to the objects, for instance if we can sit on it or where we can put our fingers in. And we successfully anticipate possible handling and mechanical constraints of objects. Well designed artefacts stimulate these expectations by indices – visual cues communicating their handling – and by that make a product self-explanatory and easy to use. "Which parts move, which are fixed? Where should the object be grasped, what part is to be manipulated? [...] What kind of movement is possible: pushing, pulling, turning, rotating, touching, stroking?" [6] Needless to say that the induced expectations should be met at the end. Elements that look moveable should be moveable in the expected way.

CAN INTERFACES BE NATURAL?

Most of this kind of everyday knowledge today is not "natural" but deeply rooted in technology driven culture. Interaction with light switches, bicycles or books may feel natural for us, but it is artificial. In any case there is not too much difference in figuring out how we can climb a tree (natural), or how we can use a knife (artificial). Both is based on experience, which implies that it has to be learned in the first place no matter if natural or artificial.

The same is true for virtual interfaces. We make assumptions about how they can be operated and controlled based on experience. This experience today primarily is experience with other virtual interfaces and only in the second place it is based on knowledge acquired while interacting with physical everyday objects. When test users of a gestural interface were asked what kind of gesture they would expect for accessing a selected item, the majority proposed pointing at it twice – a double tap in the air. [7] This is clearly not a natural gesture, but it has been internalised in years of performing double clicks in standard desktop interfaces. With more and more people growing up with digital media, the discrimination be-

tween knowledge from the analogue world and knowledge from the digital domain seems to be antiquated and obsolete. For so called "digital natives" a double click is more familiar and feels more natural than cracking a nut or peeling an orange.

When everyday objects are used as interface metaphors some interaction techniques will be anticipated and expected, but the intersecting set of possible interactions shared by real and virtual artefacts is actually rather small and is determined entirely by the software design. So there are two gulfs to bridge in order to use such an interface effectively. One is the difference between what the real objects allows or affords to do and what the virtual one does not. The second gulf is the difference between what the virtual interface allows or affords and what the real thing does not (see figure 1).

Invisibility and Intuition

Actually the problem is not the difference between the two sets of interaction possibilities but the lack of knowledge about it. In interfaces with a hyperrealistic reproduction of everyday objects this lack of knowledge is mainly caused by a lack of visibility. The interface lacks visual cues of what is operable and what is not.

Despite this conflict between real life metaphors and visibility, Apple also recommend to pay attention to readily identifiable interactive elements: "Controls should look tappable. iOS controls, such as buttons, pickers, and sliders, have contours and gradients that invite touches." [4] Already a superficial analyses of iOS applications shows that this works fine in abstract interfaces where clickable elements are clearly discernable – by visibility and by convention. But real life metaphors often lead to inconsistencies. Shape and materiality of virtual objects "invite touches" where touching has no effect. Then again clickable and movable objects are not identifiable by the eye: paper pages do not look scrollable, telephone numbers do not look clickable.

For decades mobile device interaction lagged behind desktop software, mainly due to hardware limitations. Since the introduction of the iPhone in 2007 it has been the other way round: interaction techniques of mobile devices drive innovation in standard desktop interaction. Apple continue to implement multitouch gestures, which were developed for mobile touchscreens, to classic input devices like the trackpad and the "Magic Mouse" a mouse with a multitouch area on its upper surface. In the tradition of the "direct manipulation" interaction paradigm, this is said to make interaction more intuitive: "New Multi-Touch gestures [...] let you interact directly with content on the screen for a more intuitive way to use your Mac." [8] Several different definitions of intuition exist in philosophy and psychology. It is probably easier to agree on what intuition is not: It is not a discursive or conscious process of reasoning. It rather is a way of judging and decision making without analytical reflection, mainly based on tacit knowledge. Tacit knowledge is indeed unconscious. But it is also, like knowledge in general, based on experience – that means it has to be learned. For instance there is no "natural" way of interaction with a map, because using maps is already a cultural technique. Once we learned how to work with real maps this knowledge can be helpful to work with digital maps as well. Touching and moving maps around works intuitively indeed, but Apple offers more: "New gestures include momentum scrolling, tapping or pinching your fingers to zoom in on a web page or image, and swiping left or right to turn a page or switch between full screen apps." [8]

The popular two fingers "pinch" gesture to zoom maps, images and websites is not intuitive at all: Neither the interface shows any sign that would indicate "pinchability", nor does the idea of a real map or photograph suggest "zoomability". Again the problem is that the virtual artefact does not actively communicate what kind of interactions are possible in addition to our tacit knowledge from the real world. The pinch gesture is successful, not because it is so intuitive – it simply isn't. It is merely easy to learn

and easy to remember. Actually it is not based on a real life metaphor – in the physical world it is hard to find any example where objects can be scaled by simply moving two fingers. But still it is learned and remembered easily due to the simple analogy it is based on: A change in distance of the two fingertips is proportional to the change of the size of the touched object. Accompanied by direct visual feedback the logic of this interaction method is understood immediately.

But without knowing that one can "pinch" a map or a photograph hardly anyone one would try. This simple fact does not attract too much attention because seeing the gesture just once in one of Apple's TV commercials for the iPhone or the iPad will suffice to understand and remember. This leads to the conclusion that interaction does not need to be intuitive, but has to be learnable.

Conclusion

Merely copying reality does not necessarily lead to understandable interfaces. When using real life metaphors, designers have to be very conscious about interaction disparities between real and virtual objects.

Much more important than intuition is a good balance of learnability and effectiveness. What a good balance is of course depends strongly on the type of user and the context. Especially in professional software intuitive use and learnability do not have to be top priority. In the long run rather ease of use and effectiveness are crucial. For a software that is used on a daily basis and for years some learning effort for the sake of effectiveness will be worthwhile.

The terms "simple", "easy" and "intuitive" seem to work perfectly as marketing phrases. As general and universal goals in interaction design they should be refused. Often easy to use artefacts do not have too much potential and power. Just take a violin and a triangle (the percussion instrument) and consider their learnability and their potential – probably not everything in life should be about ease.

THE LIGHT AT THE END OF THE TUNNEL: AN INTERACTIVE INSTALLATION IN PUBLIC SPACE

Selin Ozelik

While the interactive media become ubiquitous in public space, how it communicates with its site stays as a question. In this paper, an alternative answer is offered by analysing a multimedia installation focusing on how the social components are triggered by digital interaction. Consequently, the importance of social integration and social-site-specificity become apparent as additional components in the design of interactions in public space.

no caption

"Like all social practice, spatial practice is lived directly before it is conceptualised..." [1] (Lefebvre 1991)

It was a rainy day in April 2010 in Frankfurt. As one of the most central junctions of the city, Willy Brandt square was crammed with many people who were hastening to their goals. People who were hurrying up to the main station, waiting for their trams at the tram station, waiting in a line in front of the theatre, walking through the opera building at the bank square. Business women, business men, students, employees, unemployed, visitors and habitants of Frankfurt, old people, young people, children...The passers-by of this junction were streaming to the underground metro station as the rain flows to the underground.

A man's shouting was heard at the metro station 'I am Paul Auster! It is not my real name!'. People could not realise what was happening down there. 'You are the baleful one, that maculates the country', the other one answered accusingly. Then a scared young woman stated 'I think... you never had loved'. Then another woman was proud of herself stating that she had a mission there. Surely, people could not understand what was happening at their usual metro station on that day overhearing the loud yells of all these people. After a few steps a light theatre welcomed them at the top of the escalators with the voices of Quinn of Paul Auster, Terasias of Sophokles, Lulu of Wedekind, and Motte of Stockmann under the stage lights.*

'The Light at the End of the Tunnel' is an interactive sound and light installation, produced by Atelier Markgraph GmbH in collaboration with city theatre Schauspiel Frankfurt, Martin Lighting Professionals and the station managers VGF, for the fifth Light Culture Festival, Luminale 2010 in Frankfurt. The Light Culture Biennale, Luminale, is held parallel to the Light + Building trade fair every two years in the city. [2] It is a creative platform which makes the light professionals and lighting artists, designers, urban planners and architects meet, and gives them an opportunity to illuminate all over the Rhein-Main region collaboratively and innovatively. During the festival, the city becomes an open space to create site specific illuminances. Around 150.000 visitors of the festival witness a colourful ambience around the sky scrapers, on the historical museum buildings, at the public squares and through the boulevards of the city. That is to say, during the Luminale the light becomes a medium to transform the city into an art space creating new visual experiences through it.

Hosting also the city theatre, Schauspiel Frankfurt, the underground station at Willy Brandt square is a meeting point of thousands of people during the Luminale. With four entrances and three floors, it is an intersection of six underground metro lines. Within a human traffic, the passers-by's experience of 'the Light at the End of the Tunnel' starts at the entrance of the station with the voices of the actors from the original theatre plays, and with the guidance of floor markings. After walking through these, at the B-level of the station, people encounter a bright, colourful theatre scene with moving stage lights and an eight-meter-long LED panel. It is a set for passengers and passers-by whose audience are the people driving the escalator. As they move on the stage, they can activate quotes taken from current plays at Schauspiel Frankfurt. By stepping on one of the role markings, a passer-by can trigger the stage lights which spot him, the LED panel which lights the quote of corresponding character of the role marking, and the sound which is vocalized by the theatre player. In this means, a multimedia performance takes place interactively. A quote from a classical play and another one from a contemporary play were embodied by the participants like a conversation. Similar to the stage at 'Théâtre de l'espace'**, 'spectators experienced the scenes juxtaposed with one another, whether in a planned confluence or a chance intersection of sights, sounds, and narrative.' [3] With this interactive setting, a passer-by creates his/her own theatrical narrative by experimenting different roles of this interactive play. Additionally, s/he can be a part of a common performance where the other fellows act on the stage. In both cases, purposely or unknowingly, people, who only pass by, become the actors or the audiences of a theatre play which narrates 'the moment' in this specific public space.

That is to say, it can be claimed that 'The Light at the End of The Tunnel' is nourished with its potentials in enhancing these moments and in triggering social interaction among people. Besides that, it also sustains the social interaction supporting the social function of its public space as a component of digital interaction. It uses light, sound, graphic not only as architectural components but it congregates them via interaction and supports the public content of its site. Beside the regular function of this public space, it provides people an opportunity to involve in creating another social layer in this public space. A metro station, as a place where people only go by, is transformed into a public space where an additional social communication level achieved via multimedia. They pause, they share moments and create their own narratives with fellows or with strangers using interaction. They try to catch the stage light on themselves, jumping on to a classical role from a contemporary one to create an absurd dialog or moving continuously to change the light ambience of the whole room. With the presence of such an interactive installation at a metro station, people become aware of the 'publicness' of this public space that they have already become a part of, and start to construct a new kind of social relation with people around them. It is definitely a physical intervention to their usual, mundane, every day space which creates awareness via attention, participation, collaboration and performance taking place in this public space.

Thus, 'the Light at the End of the Tunnel'*** becomes also a catalyst to arouse social interaction there. In this sense, this place gains a public layer beside its functionality where people share an experience. In that means, if McLuhan's approach of 'the light as medium itself' is considered, it can be claimed that, 'the Light at the End of the Tunnel' transcends being a 'light bulb' [5] with the communicative exchange with its public. Within a context of a light festival, it intervenes the public space creating a dynamism in social interaction. This is because it is not only site specific in terms of architecture but also site-specific for its social context. With this social-site-specificity, the installation as an 'intervention' in the public space becomes an 'integration' into the public space by stimulating and supporting its publicness.

References and Notes:

* In this project, ten roles and around fifty quotes from the plays in the April 2010 programm of Schauspiel Frankfurt were selected for the interactive setting. These plays were 'Antigone' of Sophokles, 'Oidipus of Sophokles', 'Das blaue blaue Meer' of Nis-Momme Stockmann, 'Lulu' of Frank Wedekind, 'Stadt aus Glas' of Paul Auster, 'Phaedra' of Jean Racine and 'Geschichten aus dem Wiener Wald' (Anonymous).

** *Théâtre de l'espace* is an experimental space performance by Architect Edouard Autant and actress Louise Lara. In Gray Read's words this experiment 'used theatre to investigate architecture as an art of situation, of placing people in meaningful spatial relationships with one another. Autant designed the *Théâtre de l'espace* to model the experience of an urban plaza with multiple, simultaneous scenes that both surrounded and were surrounded by the audience. Performances juxtaposed fictional narratives, improvisation, and real situations to propose a paradigm for public space in a modern, collective society. Through theatre, Autant and Lara investigated architecture not as form but as action, a practice particularly relevant to design in cities.'

THE RHETORIC OF THE JPEG

DANIEL PALMER

As a method of compression for digital photography associated with the World Wide Web, the JPEG is today the default mode by which we experience on-screen images. Curiously taken for granted in discussions around digital photography, this paper asks what is at stake in the development and implementation of this standard, and proposes that the JPEG is a social and ideological phenomenon.

JPEG compression artifacts (saved at low quality) Image credit: Daniel Palmer.

Fifty years ago, Roland Barthes famously called the photographic image “a message without a code”. [1] Barthes was concerned with its illusionary transparency or ‘photographic paradox’, the double structure of what he called ‘denoted’ and ‘connoted’ meanings operable in the reading of any photograph. Three years later in his essay “The Rhetoric of the Image” (1964) – hinting at the medium’s indexical nature that later preoccupied him in *Camera Lucida* – Barthes tells us that the relationship of signifieds to signifiers is not one of ‘transformation’ but of ‘recording’. As such, he argued that *reading* a photograph involved relating it to a rhetoric – all the social codes within which signs make sense to readers (including the function of postures, expressions and gestures; associations evoked by depicted objects and sequences; and accompanying text). Yet the image itself, Barthes argued, is “a message without a code”, since being “captured mechanically” it does not involve “rule governed transformation.”

Charge-coupled devices (CCD) were already under development when Barthes published those essays. By 1969 CCD sensors could convert photos to electrons, collecting light and converting it to a voltage charge and a numerical code. And by the mid-1970s, computer programmers set to work on developing

compression techniques that would eventually lead to standards such as JPEG and TIFF. Digital photography is encoded all the way through, in elaborate algorithms built of zeros and ones, yet this code remains as invisible as the social codes that govern the reading of images. Under normal circumstances, when we see a digital image on-screen, or printed on paper, its numerical basis is repressed. The makeup of the image only becomes visible when the algorithms are pushed, typically in the form of cosmetic disturbances such as jagged edges. Usually undesired, compression artifacts – and other blocky raster effects – are like the accident in Paul Virilio's economy of speed, unforeseeable but substantive. Compression artifacts have themselves become the basis for creative exploration, most famously in Thomas Ruff's *jpeg* series, which ironically demand to be seen in the flesh, rather than on-screen.

What is a JPEG? The Evolution of a File Format

As a method of compression for digital photography closely associated with the World Wide Web, the JPEG is today the default mode by which we experience on-screen images from computer monitors to mobile devices. According to a 2011 press release from the official site of the Joint Photographic Experts Group that gave their name to the format, over a trillion JPEG images have been created (see www.jpeg.org). The same press release states that the format has “contributed to the progress of e-commerce, where digital images offer new opportunities in the form of products and services” and that “the existence of standard image coding formats” has been an “enabler” of our “digital imaging ecosystem”. Facebook and Flickr are celebrated as part of that ecosystem, while the growth of the online pornography industry is unsurprisingly neglected (Thomas Ruff once again draws our attention back to this theme in his *Nudes* series).

Most photographers and media theorists – surely everyone reading this – know that the JPEG is a technical standard that specifies how continuous-tone image data is compressed into a stream of bytes and decompressed back into an image. Beyond that, the JPEG is strangely unknown, almost completely neglected in the critical literature around digital photography. On the one hand this is unsurprising; after all, most photographers barely understood the history of Kodak, Agfa or Fuji film stock either. It was just a neutral substance, and the choice to use one or the other was based as much on habit as aesthetic preference. As for the (art) history of photography, where the final image is privileged, discussion of the technical means of its production is considered vulgar (even as this is a regular topic of conversation among photographers themselves). But the JPEG is different from film, since it is not something we choose to use, being built into cameras and the default file-sharing format. Undoubtedly its history – buried in reports and technical releases – is obscured because it appears so ‘natural’, and so concurrent, to the digital era. And indeed, its history is unremarkable. Following early research in the 1970s around the ‘discrete cosine transform’, international standards bodies began the push for an image compression standard in 1982. This resulted in the formation of the Joint Photographic Experts Group in 1986 – as a joint committee between the International Organization for Standardization (ISO) and the International Telecommunication Union (ITU). The official standard dates to 1992 in Geneva.

As part of that “general interface between systems of equations and sensory perception” – as Friedrich Kittler describes computing – the JPEG format was designed to exploit the human eye's differing sensitivity to chrominance and luminance, to discard information that the eye cannot easily see. [2] Essentially this means the so-called ‘redundant data’ of subtle color distinctions and high frequency brightness variations. However, since the quality of the image declines as this data is removed, JPEG compression is considered ‘lossy’. The original format offers only 8 bits of data per color, providing a relatively coarse

256 levels between complete darkness and complete brightness. Images containing large areas of a single color, such as blue skies, are therefore particularly prone to compression artifacts. Nevertheless, a 20:1 compression ratio can be achieved without noticeable loss of quality. If rhetoric is classically defined as “the art of adapting discourse, in harmony with its subject and occasion, to the requirements of a reader or hearer”, the rhetoric of the JPEG involves reducing an image’s file size to the minimum without drawing attention that loss.

Smaller file sizes are useful for two obvious reasons: to save memory or disk space, and for faster transmission across networks. Since JPEG compression was developed at a time when memory was expensive, camera makers welcomed more images fitting on a memory card. Moreover, the release of the JPEG format coincided with the first popular graphical web browser, NCSA Mosaic, in 1993, quickly followed by Netscape, Internet Explorer and the popular explosion of the Web in the mid-1990s. In those early years, so-called ‘progressive JPEGs’ divided image files into a series of scans for progressive rendering as they loaded over slow dial-up modem connections. Each scan gradually improved the quality, with the image slowly losing its blurriness and becoming clearer. But even this did not stop me from choosing the option of ‘turning off images’ in the browser preferences – an option still available on many web browsers.

As Lev Manovich suggested in 1995, rather than “an aberration, a flaw in the otherwise pure and perfect world of the digital”, “lossy compression is increasingly becoming the very foundation of digital visual culture.” [3] Indeed, amateur photographers have proved unexpectedly content to accept a lower quality image for the convenience of digital speed. Kodak, in particular, eventually admitted their early miscalculations on this front. As the bulk of their profits had come from manufacturing film, Kodak came belatedly to promoting digital cameras for obvious reasons – and not least as they mistakenly believed that film sales would continue to flourish simply because celluloid produced a superior image. Kodak, perhaps more than any other company, should have realised that economics and efficiency always win out over image quality.

Image quality remains the primary discourse in which JPEGs are understood by the photographic community. A typical online photo-lab will offer advice regarding the level of JPEG compression that “will not lead to visible loss in quality or detail.” More dramatically, a best-selling guide to Photoshop proposes that: “shooting in JPEG mode is like taking your film to a high street photo lab, throwing away the negatives and then making scans from the prints.” [4] The argument here – spurred on by the rise of so-called RAW and DNG (digital negative) files – is that JPEGs are degraded, even inauthentic, copies. It echoes a common misconception about JPEG images that they degrade each and every time they are opened. For serious amateurs and professionals, RAW and DNG files are akin to ‘digital originals’. Even more than compression is at stake: JPEGs are associated with ‘destructive editing’ and tied to ‘in-camera’ processing of qualities like colour balance and sharpness, as opposed to the ability to post-process such settings in software like Photoshop, Lightroom or Aperture. In many respects the RAW vs JPEG debate thus updates the craft versus automation tension that Julian Stallabrass discusses in his 1996 essay “Sixty Billion Sunsets”. [5] On one hand, the drive behind JPEG-producing point-and-shoot camera design is to automate what used to be called ‘previsualisation’ – most recently including smile-activated shutters and ‘face recognition’ that prioritise the focus and exposure when a familiar face appears in the frame. Stallabrass’ argument – that relieving the camera user of manual control has the paradoxical effect of *mystifying* the camera’s processes – still holds. Indeed, iPhone apps even play with the automated ‘developing’ of JPEGs in nostalgic ways (leading to recent minor controversy when photojournalist Damon Winter won an award for using the Hipstamatic app in Iraq). On the other hand, the economics of film-less photography also encourages photographers to ‘over-sample’ the subject, and defer their

imaginative conception of the image to its post-processing. The increasingly widespread awareness that to post-process JPEGs is to risk an avalanche of artifacts has at least focused attention, among serious amateurs, to file formats, including the issue of the proprietary nature of RAW files and format obsolescence.

More importantly than image quality, the JPEG format is part of the new computational logic of photography. Crucially, all digital cameras also save JPEG files with EXIF data – an acronym for Exchangeable Image File. The term exchange is key here. The camera model and settings such as shutter and ISO speed, aperture, capture date and time, focal length, metering and flash mode, and geolocation are all stored as metadata – helping to enable images to be catalogued, searched, shared and used. Likewise, descriptive tags – increasingly semi-automated via software may also be built into the JPEG image via EXIF data. This metadata is fundamental to the workings of photo-sharing and social networking sites, and is part of the way the JPEG protocol enables *interoperability*. [6]

The Ideology of the JPEG?

The underlying question in this paper is: in what sense is the JPEG file format significant to or even determining of photographic cultures? That is, what are the unexpected consequences of a file format that has become the universal standard? My approach borrows from the emerging field of study known as ‘software studies’. Lev Manovich, pioneering the field, has argued that there is no such thing as digital media in general, no “properties of a medium”, only operations and affordances defined by software. [7] More recently Manovich has argued that software studies aims “to investigate both the role of software in forming contemporary culture, and cultural, social, and economic forces that are shaping development of software itself”. [8]

Jonathan Sterne’s work on the mp3 as an historical, cultural and political phenomenon is instructive here, enabling us to think about the JPEG as a format whose ubiquity across devices facilitates particular photographic practices. As Sterne notes, the mp3 is a form designed for massive exchange, casual listening and massive accumulation. As he argues: “The possibility for quick and easy transfers, anonymous relations between provider and receiver, cross-platform compatibility, stockpiling and easy storage and access” were all “built into the [file] form itself.” [9] Precisely the same can be said of JPEG. Adrian Mackenzie, in an article on ‘codecs’ in Matthew Fuller’s book *Software Studies: A Lexicon*, has shown the complexity of examining the MPEG format, arguing that its performative calibration, within precise “psycho-perceptual parameters”, “refers implicitly to a great number of material entities ranging from screen dimensions through network and transmission infrastructures.” [10] All of which is also true of JPEG.

Paul Caplan has recently argued that “protocols such as JPEG and XML ‘determine’ a new scopic regime characterised by network relations which is built around a discourse of ‘the archive’ and an ideology of visual democracy.” [11] Caplan describes the JPEG as a protocol object, so familiar that it has “become transparent and taken for granted.” [12] In this sense JPEG extends the discourse and sales pitch of photography, which has always been one of ease of use, accessibility and openness – that it is, “a nominally democratic medium”. But as Caplan also observes, “this discourse of participation is clearly ideological when these imaging practices are located within the complex relations of ownership, control and power”. [13] The new scopic regime is articulated around networks that are closed, proprietary, its “image spaces, existing as part of new media giants’ such as Yahoo and Google’s portfolios of data-spaces primed for mining and advertising, are actually private commodity spaces”. [14] Borrowing,

among others, from Bruno Latour's 'actor-network theory' and Graham Harman's 'object-oriented philosophy', Caplan treats "the jpeg compression protocol as an 'actant' doing things in the world: making images findable and viewable in browsers; making them small enough to be distributed and exchanged in mobile spaces; playing a part in Facebook's face recognition business plans and Apple's App store domination." [15] The JPEG is thus 'enfolded' in imaging practices and industries, not to mention the economic-political relations of Web 2.0.

In the popular imagination, the JPEG stands for the democratisation of image making and the global distribution of the image. Take the rise of the amateur in news reporting. Iran was labelled 'The JPEG Revolution' on the front page of the *International Herald Tribune* newspaper in 2009. Indeed, we can be grateful that the JPEG is a royalty-free, open-source codec established by a non-profit UN-style organisation. Yet the primary motivation of the JPEG committee is to accelerate the adoption of new imaging products and services by the market. Today, as Caplan notes, images must become JPEGs, either captured or converted as such, if they are to find a place within social media. [16] By making the JPEG standard freely available, software publishers and hardware manufacturers can integrate support for the new file format into their products. Furthermore, the openness of the format is far from guaranteed. For instance, the JPEG committee recently formally adopted JPEG XR – extended range – as part of the continual evolution of the format. Although what was eventually ratified is an open format, Microsoft had hoped to retain some proprietary control when it submitted its 'HD Photo' format to the international standards organization in 2007 with greater dynamic range, a wider range of colors, and more efficient compression.

In 2010, Google – as part of its "make the Web faster" effort – announced a new WebP graphics format (pronounced 'weppy') with claims that its use could cut image file sizes by 40 percent. In a move that once again demonstrates the socio-technical basis of digital aesthetics, WebP has a tendency to blur images rather than create a JPEG like blocking – and is therefore better for facial skin tones in particular. Earlier this year, Google quietly slipped this potential 'JPEG killer' into Gmail, Picasa and its Chrome browser. If used, these Google interfaces automatically and invisibly convert JPEG images to WebP. Google's move is directly related to its effort to push their new web video format, WebM. In any event, faster file transfers and lower network burden are obviously attractive for Google, who point out that images make up 65% of the typical data of a web page. But there are penalties: encoding and decoding WebP images takes significantly more distributed computing power. And while both WebP and WebM are open formats, we should never forget that all the data around online images gets mined to become part of valuable algorithms to be patented and used to direct the unpaid labour of online attention through which audiences provide the basis for the advertising economy.

After twenty years, the JPEG is a powerful incumbent – built into every camera, Web browser, image-editing program, pharmacy photo-printing kiosk, and mainstream operating system in existence. These material environments illustrate the complex forces and relationships within which practices of digital photography operate, and invite us to move away from perspectives that seek the essential characteristics of the technology. By virtue of its ubiquity and association with the Internet, the JPEG is rhetorically tied to the idea of democracy in an age of distributed imaging, in which the image has been spatialised in global databases. More broadly, the very manner in which computer software in general separates the (image) interface from algorithm "makes it a powerful metaphor for everything invisible that generates visible effects, from genetics to the 'invisible hand' of the market", as Wendy Chun has recently argued. [17] The rhetoric of the JPEG, its persuasive power, lies in this same invisibility. As with the very idea of 'analogue photography', perhaps only once it is outmoded will the JPEG move into the critical light.

EXAMINING ISSUES OF BODY IMAGE AND COMPLEX REGIONAL PAIN SYNDROME WITHIN THE DIGITAL

MARK PALMER

Drawing upon the creation of a digital tool to replace self portrait sketches in the diagnosis of Complex Regional Pain Syndrome we will examine the body's depiction in the digital, drawing upon patient interviews to explore how the digital can help us understand our body image. In so doing it will challenge phenomenological accounts of the body and seek critique the structures that often assert the digital as an incorporeal space.

Introduction

Body image can be altered by pain, 'peripheral' injuries such as amputations, or insults to the central nervous system. These conditions have also formed the basis of Merleau-Ponty's philosophical enquiry into how we might understand embodiment. Within clinical practice attempts are made to 'repair' patients' body image through rehabilitative techniques however the means of assessing these changes has been that of self-portrait sketches.

The use of self portraits has been problematic in that it has often been limited by the abilities of the patient and, not without irony, the additional limitations that the condition itself can place upon them. Alexa Wright's work on the Sci-Art funded *After Image* project (1997) investigated the phenomena of phantom limbs however the techniques involved in creating these images were not ones that could be easily utilised by patients within a clinical setting. As a result of this research was instigated that examined the possibilities of the manipulation of an avatar for suffers from Complex Regional Pain Syndrome (CRPS) within the Digital to communicate their experience of their body image. This was instigated by allowing patients to remove, scale, displace and render the body in a variety a ways.

This paper will examine issues concerning the perception and depiction of the body within the digital. It will draw upon research interviews with users of the system to explore how the digital, rather than promoting notions of 'virtual' self can help us understand our experiences of the physical. In so doing it will draw upon a phenomenological understanding of embodiment and seek to critique the structures that often assert the digital as an incorporeal space.

Complex Regional Pain Syndrome (CRPS) was first identified during the American civil war when it was named *Causalgia* derived from the Greek words for pain and heat which are symptoms typical of the syndrome. CRPS is associated with the body's extremities and can affect whole limbs. It is defined by two forms, Type 1 (CRPS1) and Type 2 (CRPS2), but the nature of the pain of this is common to both forms. In CRPS 2 the pain can (albeit disproportionately) be associated with identifiable nerve lesions or tissue damage however in CRPS1 there is no identifiable injury that can be associated with the pain that is suffered.

Our understanding of CRPS is still in development and there are still different sets of criteria for its diagnosis; a situation most likely exacerbated by the fact that many of its symptoms are not identifiable through the use of objective tests. As we have noted a common factor is chronic pain associated with heat; this is accompanied by extreme sensitivity and painful reactions to everyday sensations such as the touch of clothing. Along with this there are a range of other symptoms that may be experienced that can include the perceived (and sometimes actual) swelling of limbs and the sense that the affected region does not belong to the patient; in some cases this can lead to a desire to have the limb amputated. Perhaps one of the most perplexing aspects of these symptoms for patients and clinicians is that they can vary greatly through the course of a day.

As a result of these factors there has been a tendency to believe that there is a psychological basis to CRPS. However a systematic review^[1] of research concerning this relationship has suggested that there was 'no relationships between psychological factors and CRPS1'. In fact the frustration of trying to understand and convey these symptoms can be more of an issue, in fact one patient involved with our study noted that 'I really thought I was losing it.'

If the range of experiences described are not the result of the patient's psychological makeup how might we begin to understand these symptoms?

Body Image

Although body image is susceptible to distortion through psychological factors (as seen in conditions such as anorexia nervosa) neurological studies have shown that other factors play into its creation.

Work by Ehrsson, Holmes and Passingham's has sort to investigate this through an investigation of the "rubber-hand illusion". The illusion concerns the perception that a rubber hand was a part of a subject's body; this was generated by providing sight of a rubber hand being brushed whilst simultaneously brushing the subject's hidden hand. Ehrsson et al sought to establish whether the illusion was more than simply a result of the visual representation of the hand being brushed. This was tested by blindfolding their participants and moving the subjects hand to touch the rubber hand whilst simultaneously touching the participants hand in the 'same' place.

The results demonstrated that the illusion could be generated though synchronous touching without the need for a visual representation. Further tests also asked subjects to locate the index finger on the hand subject to the illusion. This revealed an error in locating the finger that appeared to be dependent upon the veracity of the illusion. Given this it appears that the illusion's power was such that it remapped the perception of where the participant's hand was in space.

The Role of the Somatosensory System

The Somatosensory system incorporates the receptors and processing that provide our sense of touch, temperature, body position (proprioception) and pain (nociception). McCabe, Cohen, Hall, Lewis, Rodham and Harris have proposed that disruptions within the somatosensory system can begin to account for the symptoms described within CRPS [2]. They note how our body image is formed through the

...integration and processing of multimodal sensory percepts that involve the peripheral nervous system and central nervous system (CNS)... This is not a unidirectional system, whereby the CNS simply responds to a peripheral stimulation, but is a bidirectional process in which CNS activity may induce consequences.

This has some reaching consequences for our understanding of what we might understand body image to be. We often assume that our bodies are a given around which our perceptions are formed. The phenomenologist Edmund Husserl notes that

The Body is in the first place the medium of all perception...the zero point of orientation... each thing that appears has eo ipso and orientating relation to the body. (Edmund Husserl, *Ideas II* trans. Rojcewicz & Schuwer, Kluwer, 1989 p 61)

This is perhaps most clearly expressed in the phenomenology of Maurice Merleau-Ponty.

If my arm is resting on the table I should never think of saying that it is beside the ash-tray in the way the ash-tray is beside the telephone. The outline of my body is a frontier across which ordinary spatial relations do not cross. This is because its parts are interrelated in a peculiar way: they are not spread out side by side, but envelope each other. (Maurice Merleau-Ponty, *The Phenomenology of Perception*, trans. Colin Smith, Routledge, 1962 p98)

Phenomenology quite literally places the body centre stage and one might even claim that Merleau-Ponty's philosophy is based around an a-priori status for the body. In contrast to Merleau-Ponty's assertion, within CRPS we discover patients who can experience a limb to be foreign to their body and who possess 'a poor awareness of its location in space'.

In fact when asked to move an affected limb suffers of CRPS often do not move the limb itself but move from the unaffected part of their body as if the limb were an *object* within their peripersonal space (and therefore affectively 'besides') their body. In this regard we discover circumstances within which ordinary spatial relationships *have* entered the body.

Rather than possessing the body as a 'given' to which sensation 'adheres' it appears that body image emerges from the relationship between sensation and the CNS. Given this the 'enveloping' to which Merleau-Ponty refers effectively occurs prior to the body image. If sensation is not something appended to the body 'External' sensation and proprioceptive perception by necessity will envelope each other as they are processed by the CNS generating our body image and sense of space.

Changes in Body Image

Our somatosensory system is known to be involved in more than just the perception of what we might consider to be our own sensations. When viewing the experience of others and imagining activities of various sorts the somatosensory and premotor cortices becomes active. Antonio Damasio describes the empathetic sensation of pain that we can experience as the “as-if-body-loop” mechanism.

It involves an internal brain simulation that consists of a rapid modification of ongoing body maps. (Antonio Damasio, *Looking for Spinoza*, Heinemann p 115)

However the notion of a body map is in itself problematic as Damasio points out

The result of the direct simulation of body states in body-sensing regions is no different from that of filtering of signals hailing from the body.... What one feels then is based on “false” construction, not on the “real” body state. (Ibid)

Damasio’s use of scare quotes is appropriate because the sensation is real, what differs is that in that empathising with somebody who has grazed their knees although we’ve physically not gone through that event we experience it in another way. Similarly the experience of CRPS patients is real even though they apparently possess a ‘normal’ limb.

A condition that has similarities with CRPS is Fibromyalgia (FMS). The symptoms of FMS include widespread pain, hypersensitivity to sensory stimuli, phantom swelling of limbs and reduced sensitivity to the position of limbs and motor abnormalities such as tremors or slowness in movement.

In order to examine whether a dysfunction in the interaction between motor and sensory systems might be involved in symptoms experienced in FMS McCabe et al conducted a series of tests using a mirror/whiteboard that created varying degrees of sensory conflict during congruent/incongruent limb movements. The results of this were that 89.7% (26 out of 29) of patients with FMS involved in the tests reported changes in perception compared with 48% of a healthy control group. The sensations experienced included...

...disorientation, pain, perceived changes in temperature, limb weight or body image. Subjects described how these symptoms were similar to those they experienced in a “flare” of their FMS. This led us to conclude that some sensory disturbances in FMS may be perpetuated by a mismatch between motor output and sensory feedback.

Whilst it appears that this mismatch plays a role within FMS it was also the case that the healthy participants also reported (albeit at a lower incidence) changes in perception. Rather than being a phenomena exclusively linked to the pathology of FMS the results of these tests point towards what appears to be the emergent nature of body image as an a priori condition of perception. The anomalies that appear to exist within FMS therefore appear to make those who suffer from the condition all the more vulnerable to new anomalies. Given this it would appear that within CRPS such disturbances are exacerbated.

Given the close integration between (the enveloping) of body image and spatial perception it appears that conflicting sensation, proprioception and visual perception or faulty sensory integration might explain the experience of CRPS patients who have difficulty in locating their limbs or who feel that they are not a part of their body.

Communicating Painful Contradictions

The right side of my whole body actually feels quite normal, there no problem with that I don't have any difference in perception to what I see with that...

Because of the fact that CRPS is not well known diagnosis can often take some time. As was noted by one patient in our study

The thing I found difficult was getting this far, my GP knew nothing, so the diagnosis took forever...

During this period patients suffering from CRPS often doubt themselves because of the contradictory nature of their experiences.

A method currently used in assessing CRPS is the use of self portrait sketches or drawings made by clinicians; these have a number of limitations such as the ability of patients or staff to render these sensations. These are often revealing for those suffering from CRPS because it can often be the case that patients have not fully considered the nature of their sensation. It appears that they have often been trying to deal with the contradictions rather than 'inhabit' the sensations resulting from CRPS. One patient noted that

...its quite new to me because I hadn't really thought about this until I came in here.

This could be due to the nature of the sensations encountered...

I know there are fingers there and I even move them, I can't see fingers when I try closing my eyes to see it, I don't see anything, I just see a big blob

Inspiration for the development of a tool that would assist patients in communicating their symptoms came from Alexa Wright's *After Image* project which dealt with the experience of amputees and phantom limbs. Whilst Wright's work used Photoshop to manipulate photographic images of amputees this wasn't appropriate for the creation of a tool that could be easily used within a clinical setting. The spatial anomalies experienced CRPS patients also suggested that the development of a 3D tool would be more appropriate.

As a result of this a prototype tool was created that allowed the positioning, scaling and colouring of body parts to see whether this would aid patients in their description of their experiences. This was tested with patients suffering from CRPS who attending the Royal National Hospital for Rheumatic Diseases (RNHRD) in Bath.

Ethical clearance for the tests was of course required. One of our concerns was that in discussing their condition the level of pain experienced by patients often increases, as a result there were concerns that

use of the tool might negatively affect patients and so measures were put into place so that this could be addressed if it were to occur.

The tool was well received and considered to be a valuable improvement over established methods. What was interesting was that within the interviews that we conducted patients were asked if the experience of the tool was distressing for them in any way. In a number of instances increased pain was experienced but other benefits were expressed.

No, I don't think I've got a bad feeling from doing this, it's not a bad feeling it's just to me looking at that ... puts it into perspective what I've got its just I don't know how to explain it, it looks in human form exactly how I feel and I've never had that...

It was also the case that appeared that even if it hurt the process might have helped reconcile some of the contradictory sensations experienced by patients.

Patient: Seeing something and knowing that it's *your hand* is erm how can I put that into words, its erm, I don't know it I suppose accepting now that it's there, it's happened, I've got it..

Interviewer: Does this help you accept it?

Patient: *Yeah*, because you can see it...

Although the it was not something we sought to address through the use of the tool it is interesting to note that it may have benefits in the acceptance of the condition.

It wasn't that I disliked using it, it's just... for me as I say to visualise that how I feel I felt a bit emotional, but the more I'm looking at it, it's only because I'm sitting here thinking that is exactly how in my mind's eye what I look like so it was a bit of a shock I suppose.

The Nature of Pain

You can't see pain

By its very nature the tool tended to focus upon the perception of the scale, position and possession of limbs. However the depiction of the quality of pain and the degree of contradiction often experienced within that pain was something that required further development.

My hand feels as if it's absolutely on fire and then if somebody touches it, it feels cold, and this pins and needles and I don't know how to represent that...

In fact these contradictions appear to be central to the nature of the pain experienced by many with CRPS.

These fingers here are numb, I suppose in a way they should be transparent really shouldn't they... 'cause these three fingers here are numb, I feel I could just stab them, but it's still got that hypersensitivity in it.

As a result of this we have now embarked upon the development of techniques that allow patients to approach a visual description of these sensations. However the sensation of 'pins and needles' described by one patient was, to varying degrees also reported by others.

Ok so the skin surface doesn't feel any different here, but when I've got my eyes closed it's very, it almost feels as if it's... if I say it's not there you know when you've sat on your foot and its gone to sleep, its that sort of feeling so you sort of know its there but if somebody said where is it its quite difficult to say it's just there...

In itself this provokes interesting questions concerning the issue of ownership of affected body parts... what if the pain is associated with a lack of sensation?

This opens up upon one of the therapies being used to minimise the pain suffered by those with CRPS. One of the emergent techniques used in treating CRPS concerns the sensory mapping of the affected region. It has been found that sensory retraining of the limb can reverse cortical changes and reduce pain.^{[3][4]} Staff involved with the development of the Body Image tool are involved with the development of an Electrical Sensory Discrimination Therapy device (ESDT) that can improve sensory discrimination in the limb of healthy subjects and those with CRPS (funded by the NIHR^[5]).

Conclusion

What does all of this mean for the electronic arts? For many years there has been a tendency to view the data of electronic systems as being akin to the idealism of Plato. The evidence of neuroplasticity and devices developed by scientists such as Bach-y-Rita has been used to support such claims. However as we have seen vision also plays a part in the somatosensory system; it may be the case that devices such as the BrainPort naturally play into this.

However as we have seen through our discussion of CRPS perception appears to be far more complex than a simple case of sensory input and neurological output. What we need to do is to begin to develop an understanding of the ways in which the somatosensory system works and the ways in which it participates in the generation of our body image. If we were to buy into the rhetoric of a digital realm of the ideal, any attempt to achieve the production of a body image in any other world seems fraught with potential problems. However it also the case that the digital can be used to realise images that reflect the realities of that system for those who suffer from conditions such as CRPS.

I would like to acknowledge Dr Ailie Turton as co-author of this paper and thank Dr Candy McCabe for her contributions.

ON BREATHING AND GEOGRAPHY – SONIFYING THE SEVERN AS SHARED GENERATIVE ART PRACTICE

MICHAELA PALMER

Using the example of a sonification prototype that explores the Severn estuary rhythms, this paper discusses possible frameworks for larger, multi-dimensional sonifications. It explores the necessary compromises between quantifying and qualifying data and argues that skillful use of sound compositional techniques, data mapping and participatory practices can deepen and intensify listeners' experiences.

Severn Bridge, 2010, Owain Jones, photographic media, Copyright Owain Jones.

The Severn Estuary in Southwest England (fig. 1) deserves great attention: with an enormous tidal range and three million people living around its shores, it is a unique site of interlinked and clashing rhythms. Moreover, the passage over or under the estuary, industry and tourism affects a much wider, and not necessarily local, population group. This is the target audience for Sonic Severn, [1] a small but growing online collection of soundscapes, sonifications and compositions about the Severn Estuary, curated by Tidal Severn.

Using the example of a more recent data-driven sonification prototype that explores the Severn estuary rhythms, this paper discusses possible frameworks for larger, multi-dimensional sonifications. It explores the necessary compromises between quantifying and qualifying data that can influence listeners' interpretation of sounds, and discusses different kinds of 'accuracies' that may be applied in the creation of sonic representations. These accuracies are often connected with listeners' perceptions of how they are connected with this landscape. It is argued that skillful use of sound compositional techniques, data mapping and participatory practices can deepen and intensify listeners' experiences of generative processes.

The sea's ebbs and flows, storms, swirls and stagnant waters have inspired many well-known compositions, such as Vivaldi's *La Tempesta di Mare*, Debussy's *La Mer*, or Vaughan Williams' *Sea Symphony*. Some of the rhythms of the sea can be especially well grasped in tidal landscapes such as the Severn estuary. But in addition to rhythmic changes, more intrinsic links between tidal landscapes and sound practices can be made. For example, plots of tidal ranges and plots generated by sound oscillators both exhibit typical sine wave structures. Coastal gauges calculate the tide height by mathematically eliminating wave heights, while in sound synthesis gauges limit the frequency range of signals. Tidal patterns are predicted via Fourier analysis – a method that examines fundamentals and their harmonics – while in sound practices Fourier analysis can be used for the generation of overtone-rich notes. Thus many of the methods used for the analysis of tidal processes are also applied in sound synthesis.

For a tidal sonification, exploring these commonalities may seem like a useful starting point, and yet such an approach overlooks the role of human experience. A landscape like the Severn estuary is not only read logically. Once immersed in it, sensations force themselves upon us: its unforgiving wind blasts the skin and makes the eyes water, its rain sticks sand grains to the skin; we smell and taste it. Before we know it, these sensations are shaped by our internal blueprints – memories, habits, cultural norms – and so we might start to think that the wind intentionally plays with our bodies, or that the estuary teases us with mudflats and quicksand pools. Interpreting what is around us is such a strong mechanism. It informs our habitual thinking patterns and shapes our expectations. When it fails, we tend to feel let down by the situation we encounter and less so by our expectations of it. Heading for a day out at the Severn beach for instance, we might be disappointed with the vacant scrubland we find but still not question what we hoped to see.

Indeed, habitual thinking patterns are hard to break. They can easily undermine the process of sound mapping itself. If we were to map the Severn estuary sediment for example, we would encounter the following problem: although the Severn estuary has one of the best-researched sedimentary regimes in the world, it is still difficult to pinpoint the sediment location. This is because the 30 million tons of fine silt that are suspended in the estuary's waters during a typical spring tide, are not equally distributed. There are areas of denser and less dense suspension, and some areas remain stationary (pools) while others move with the tides (slugs). [2] Moreover, the amount of moved material depends on the severity of each tide, which in turn influences the re-distribution of the landmass (erosion and deposition). Thus research – as well as first-hand observation – tells us that in this intertidal environment, a simple distinction between water and land is quite misplaced: land and water here permeate each other in very unpredictable ways. And yet, when thinking about the estuary, how easy it is to picture a map in our minds where a simple coastline separates land from water.

To arrive at a new mapping strategy for the estuary, one might therefore consider an artefact that literally redraws itself with each tide. Since the coastal shape would no longer be recognizable, the artefact could orientate its users via site-specific sound beacons instead, for example the sounds of the seagull colonies on Flatholm island. Beacons like this contain information not only about the physicality and materiality of a location, but also on the condition of the sounding objects embedded in them. Thus the use of real-time sound beacons can help to experience a landscape afresh. [3]

To move listeners between locations, this artefact would have an interactive interface. Listeners would only hear sounds within a certain range of their position, like one does on sound recording trips. This can encourage discovery via comparative listening, for example the discovery of different wave sounds caused by different bathometries: at Clevedon seafront for example one might hear small waves rushing

onto a pebble-covered bay, while at Burnham-on-Sea the wide-open sandy flats only produce occasional water ripples.

To further an understanding of the interdependence of the environmental processes in the estuary, this artefact also needs to become scalable. 'Zooming out' would enable synthetic listening (listening to the estuary as a whole), which in turn allows to make new connections between different sound events, for instance between the sonified lunar zenith and its following high tide, or between wind conditions and tide height.

While this new mapping strategy provides an outline for a developmental direction, Tidal Severn's current sonification prototype is still at a much earlier stage. At the moment it taps into three kinds of data: the level of tide over the mean sea level, weather data (wind speed, direction, atmospheric pressure) which influences the tide, and the solar-lunar constellation which also affects the tide. Since tidal data is multi-dimensional and human memory limited – our short-term memory can only hold about seven items of information at the same time [4] – data interpretation becomes increasingly difficult the more data streams are used; hence the limitation of the number of data streams.

These data streams were then mapped to groups of sounds. The key technique used hereby was parameter mapping, [5] which means that changes in numeric data values affect the attributes of sounds (such as onset, frequency, duration or amplitude). In parameter mapping, the relationship between sound and data can be established as directly proportional (rising water level = rising pitch), scaled (rising water level = logarithmic rise of pitch) or otherwise mathematically defined. Thresholds, where the data indicates significant changes, can be acoustically marked, for example as flood warning sounds.

A known disadvantage of parameter mapping is that listeners need to understand the mapping strategy before they can understand the meaning of the changes in the sounds. [6] However, it was found that listeners needed less training if sound timbres were selected perceptually and applied consistently. Thus in the sonification prototype, sound metaphors (swelling and ebbing of sounds = swelling and ebbing of a water body) and self-labelling sounds (wind-like sounds = wind data) were used to allow for an intuitive attribution of sound to source. Moreover, the three sounds were acoustically grouped, each having distinct timbres (sound colours). The attributes of each group (pitch, duration etc) remained data-driven, but their timbres constant. This strategy seemed to aid comparative listening, as listeners noticed site-specific characteristics in the data more easily than when different mapping strategies were used.

Another finding was the influence of time compression on listeners' perception of the sounds. It is said we are more likely to pay attention to short sound events with a distinct change in dynamics (waves crashing into a seawall) but to ignore long drawn-out processes that show little change in rhythm or dynamics (a receding tide revealing mud flats). To explore this notion, the sonification prototype was tested with a number of time compression ratios. The data would no longer be sonified in real-time, but instead one tidal cycle's worth of data compressed into minutes. For many listeners the interrelations between the three sounds became more apparent when the data was scaled in such a way. Then listeners also seemed to become more sensitive to structured motion (rhythm) and were able to distinguish regular from unusual patterns more easily.

Indeed, if the Severn estuary rhythms were to be described by time classifications in music, the tide would fall into a 'macro timescale' of musical architecture or form, which according to Roads is measured in minutes, hours or days. [7] The tide in the estuary is duo-diurnal, which means that only after 12 hours or so it reaches the end of one basic unit of time (or beat). The relative positions of earth,

moon and sun on the other hand only repeat themselves every 19 years or so. This kind of rhythm corresponds to the ‘supra timescale,’ covering months, years, decades and centuries. [7] Since neither timescale connects to an everyday experience of duration, only an experienced observer would notice an unusual change, for instance in the monthly spring-neap cycle or the annual tidal cycle.

Weather patterns, on the other hand, fall within our everyday experience of duration, but since these are characterized by arrhythmic repetition – strong gusts of wind, or rainy days with sunny intervals are quite common in the estuary – it is not always obvious how the seemingly chaotic weather patterns relate to the seemingly regular tidal patterns. Thus a problem that affects real-time tidal sonifications is that since they do not coincide with habitual notions of duration, the cyclical nature of their rhythms may remain elusive to many listeners. On a deeper level, this leads to the question as to when artefacts that translate data into sound can actually be said to be successful.

To answer this, it is useful to turn to earlier days of sonification practice, when sonifications were defined as “the transformation of data relations into perceived relations in an acoustic signal for the purposes of facilitating communication or interpretation.” [8] According to this, the aim of communication or interpretation should guide the sound mapping process. This has not lost any of its validity, however, more recently it has been demanded that, at least within a scientific context, sonifications must also reflect objective relations in the input data, use systematic means to translate the data into sound, and should be set up in such a way that they are repeatable and reproducible. [9] What is often criticized nowadays about art-related sonification artefacts like the Severn prototype is that their algorithms are not made transparent, and so it remains unclear as to whether the sonification was carried out objectively and systematically.

In principle, this is a valid concern, yet the kind of objectivity called for is often hard to ascertain with the kind and quality of field data available. The Severn estuary is itself a part of a larger ecosystem, and so it is hard to define the boundaries of any of its data streams; for example the local weather conditions measured in the region are often the results of larger changes somewhere else in the system. It is important to understand this global link, but without limiting the data in some ways, characteristic local weather patterns may not be observable at all. A further complication is that most publically available scientific data is not updated in real-time. Tidal data for instance relies on – not completely accurate – predictions; and a weather station in Alveston that updates itself every 2.5 seconds is the nearest real-time data source in the area. Most other available data is time-delayed and/or somewhat coarse, only exposing its characteristic patterns with a degree of inaccuracy.

Objectivity is also hard to ascertain when the act of sonifying data already involves perception; at first in form of the researcher who maps data to sound, and then in form of listeners who re-interpret what they hear. Moreover, many data sources from the estuary represent vast numbers of very small elements. As humans we do not have an intuitive grasp of very large or very small numbers, and so it remains a challenge to successfully sonify, for example, 30 million tons of silt suspended in water. Since a directly proportional mapping of data to sound might not be adequate here, a more interpretative mapping strategy might be applied to aid communication. However, this already influences listeners’ perception in a particular way.

But since the role of perception is so hard to exclude, it might be useful to integrate it more explicitly into the methodology. To this end, Lefebvre’s Rhythmanalysis [10] provides a useful frame of reference, as it intrinsically connects the researcher’s thoughts and experiences with the geographical location where the rhythmanalysis takes place. With references to musical rhythms as well as tidal rhythms,

Lefebvre's framework appears as particularly suitable for a sonification of the Severn estuary, yet its adoption is not entirely straightforward. For example, when Lefebvre introduces the notion of "lunar towns of the oceans," and "solar towns of the Mediterranean," [11] this may seem appropriate on some level; tidal rhythms are still engrained into the architecture of lunar cities and present in form of estuary-related professions. However, on another level, one might wonder about individual inhabitants' perceptions of the interplay of diurnal and lunar rhythms. Thus to allow for greater self-representation of those researched, a more participatory version of rhythmanalysis is required, one that can map the polyrhythmic exchanges that actually take place between estuary inhabitants and the landscape.

To this end, researchers like Biggs have pursued a deep mapping of a small number of estuary locations. [12] Deep mapping focuses on qualitative data, which is obtained through a collaborative process involving inhabitants and concerned parties. Although "in performance and archaeological circles in the UK, deep mapping refers primarily to site-based performances by Mike Pearson, Michael Shanks, Clifford McLucas, and the radical Welsh performance group *Brith Gof*," [13] deep mapping has been used much more widely. It can reveal radical perspectives, particularly when it abandons the traditional researcher-led perspective for collaborative methods and processes. A deep mapping that involves estuary residents would be able to map thoughts and issues in their complexity and, according to Biggs, challenge "distinctions between academic and artistic outcomes, between healing fictions and scholarly critique, between amateurs and professionals." [13]

For an artefact that successfully sonifies Severn estuary rhythms, it seems, participatory practices like deep mapping need to be used alongside established data communication methods. In this way, intuitive connections between observed tidal phenomena and their experience can more easily be made. Moreover, creating the possibility of moving between measuring and sensing, between different time and map scales involves listeners cognitively as well as emotionally. As Lefebvre remarked, this can open the door to new insights:

Our scale determines our location, our place in the space-time of the universe: what we perceive of it and what serves as a point of departure for practice, as for theoretical knowledge. [...] Another scale would determine another world. The same? Without doubt, but differently grasped. [14]

And since, according to Lefebvre, it should be possible to connect with complex natural phenomena more deeply when we can relate them to our own bodily rhythms, the following may serve as a concluding thought experiment: It takes the duration of about 12000 human in and outbreaths for the Severn estuary to complete one tidal cycle. Counting thousands of breaths in order to grasp the nature of the tide is however simply unbearable, as the difference between the two durational scales is too great. But when we mentally switch scales, an intuitive connection can quickly be made: by observing how, like the tide, each breath unfolds slightly differently each time; how it naturally accelerates, decelerates, pauses and turns direction.

Dr Michaela Palmer and Dr Owain Jones are Tidal Severn, an interdisciplinary research team that provides information, teaching materials and presentations in order to raise public awareness about the Severn Estuary, a large and important intertidal landscape in Southwest England.

Sonic Severn is open to composers, sound designers and sound artists who wish to work with some of the phenomena of the Severn Estuary, in order to share what is in living memory and to open listeners' minds to the fragile relationships between human experience and local landscape.

WAKEFUL SOFTWARE AND WAKEFUL MUSICAL INSTRUMENTS: A THEORETICAL APPROACH TO THE IMPLEMENTATION

Fabio Paolizzo

A new category of content-related software is here proposed. 'Wakeful' software is one that senses and responds to an environment with which it may consistently interact meaningfully. The term 'wakeful' is here meant as 'sign-bearing,' in relation to the potential of computers and human beings to interact in terms of sign exchange.

The present proposal is based on concepts that interest any human-computer interaction that involves the generation or manipulation of content of any type. Specifically, the study was carried out in relation to music and computer-based interactive musical systems. Accordingly, the research offers definitions of both 'wakeful software' and of 'wakeful musical instruments,' which are particular types of computer programs and of interactive musical systems. In interactive music, the reasons why users and audiences can only occasionally interpret the sonic constructs as music, which an interactive system generates, are often obscure. The present study is part of a larger project that aims at defining a protocol for living being-machine interaction, in order to guarantee consistency of communication between these types of agents. Currently, the solution to such crucial problems as the above is being urgently sought in diverse fields of study, from computer science to philosophy of mind. Wakeful software is one, which respects such a protocol.

First of all, we shall give a definition of an 'interactive music system'. Robert Rowe described such systems as "those whose behaviour changes in response to musical input." (Rowe, 2001) On the other hand, a definition of 'wakefulness' implies a comprehension of what consciousness is; an umbrella term that has many different meanings and about whose fundamental characteristics there is no consensus. According to the Stanford Encyclopedia of Philosophy, while it is possible to understand consciousness as a mental state, an animal, person or other cognitive system may be conscious in the sense that they constitute forms of consciousness; they are conscious cognitive systems. In this specific regard, consciousness may be firstly identified as sentience or wakefulness. While sentience is the capability of any organism to sense and respond to its world (i.e. any living being), an organism is wakeful only when actually using such a capacity (i.e. a comatose living being might not be 'wakeful'). In both forms, the concept of 'response,' recalled by the definition, implicitly points at an act of communication, which may eventually or actually take place, between the cognitive system and the environment. The English term communication derives from Latin verb 'communicare' (to share). As pointed out by Dan J. Rothwell, a necessary condition, for a communication to be established, is that the communicating parties share a common environment of communication; they need to be capable of a similar interpretation of the messages being exchanged.

In relation to the focus of the study, the first question arises: do computers and human beings share such a communicative commonality? The present research will show that although they do not, specific techniques can be adopted for machines to simulate logics of communication, which are proper to living

beings. Such techniques may allow any human agent to consider the responses of content-related software, as either an act of real communication or a convincing simulation, to which attribute meaning. While sentience and wakefulness constitute relatively simple forms of consciousness, human beings and possibly other cognitive systems are more sophisticated; they are forms of self-consciousness. Creatures or cognitive systems, to be considered as such, need to be more than sentient and wakeful; according to the Stanford Encyclopedia of Philosophy, they are those which “are not only aware, but also aware that they are aware.” A question, which has been formulated already many times, arises here again: can a computer be conscious?

In interactive software of any kind, the concept of agency is central. A peculiar relation exists between agency and consciousness. What is the nature of this relation and how is it possible to mean consciousness in relation to agency? Is any agent conscious? Interaction between human agent and machine occurs within what is called a multimodal ambient, where agents interact with each other by different modes (i.e. as in the planet Earth). In very general terms, agency can be defined as the capacity of an agent to act in a world. However, agency differs for intelligent and non-intelligent agents. For instance, there is general agreement that human beings are intelligent agents, who are able to make choices and to enact those choices on the world. Instead, natural forces are considered to be causes that involve only unthinking deterministic processes. In this simpler form of natural phenomena, agency seems to imply only the capacity to act in an environment. However, even excluding the Gaia theory, agency often exceeds the mere capacity of action; it implies a relationship which is connoted by a decisional nature that may help to clarify the distinction between intelligent and non-intelligent agents. The English word agency derives from the Latin ‘agere’ (to do): an agreement to act on one’s behalf. Such ‘action on behalf of’ implies the authority to decide which action is appropriate. According to the Encyclopædia Britannica, “in computer science, an agent is a computer program that performs various actions continuously and autonomously on behalf of an individual or an organization.” The authority of taking appropriate decisions is a capacity that cannot be simply described as deterministic, and leads us to discuss the subject of how human beings come to make decisions.

According to Thomas Nagel, a being is conscious just if there is a subjective way, a mode of consciousness that constitutes the creature’s mental or experiential point of view. For Nagel, bats are conscious because there is ‘something that it is like’ for a bat to experience its world through its echo-locator senses. While a software agent is not a living creature, indeed certain software agents may be actually capable of sensing and responding to the environment. In which case, it makes sense to pose the question: ‘what is it like to be a software agent?’ May such agents be considered as conscious? Taking into account the above mentioned diverse forms of consciousness, software agents should be considered as capable both of sentience and wakefulness. However, can they be considered as forms of self-consciousness? Can they be aware of being aware? In order to progress toward the formulation of an answer to such a question, we will introduce few concepts from biosemiotics.

The Oxford Dictionary of Biochemistry and Molecular Biology defines biosemiotics as “the study of signs, of communication, and of information in living organisms.” This term derives from the Greek ‘bios’ (life) and ‘semeion’ (sign). In biosemiotics, “signification (and sign) is understood in a very general sense, that is, not simply the transfer of information from one place to another, but the generation of the very content and meaning of that information in human as well as non-human sign producers and sign receivers.” (Emmeche and Kull, 2011) This principle was described in different terms by the Nobel prizes Ernst Mayr and Manfred Eigen as the peculiarity of living forms and possibly, of man-made computers. However, computers are designed by humans to achieve specific goals; their teleology is derived. Instead, the informational characteristics of organisms evolved through adaptation and the same living

forms are the result of an evolution. While software agent can adapt to the world that they sense, as living beings do, for a computer such a process operates within a scenario that is to some extent predetermined by its designer. Nevertheless, two further observations can be made: in humans, the informational processes resulting from adaptation and self-adaptation are similar to each other; the informational processes by which humans and computers interact and adapt to the environment denote similar traits.

The necessary condition for self-adaptation to occur is that the mind – or whatever entity or organ may constitute the ‘mind,’ as we are considering the eventuality of self-conscious cognitive systems that do not have ‘minds,’ – needs to be attributing meanings to the perceived signs; a process of interpretation may have to take place. Interpretation is the process of attribution of meaning by which signs take shape in the mind. Any interpretation is always a bi-directional and recursive loop, since whereas the mind assigns a meaning to the sign, the sign itself is connoting the mind. This process, fundamental to forms of self-consciousness, is virtually open-ended, being the result of a recursive process of interpretation. Finally, we can now refine our question: are computers capable of interpretation?

Lending to the present investigation a few of the conceptual fundamentals of biosemiotics, it is possible to describe interactions in a multimodal ambient as recursive sign exchanges occurring between agents, whereas such an ambient includes agents capable of interpretation. We shall clarify such a statement. There is a strict relation between an interaction and an interpretation process, interpretation being a form of mental interaction between thoughts and information retrieved from the external phenomenological reality. Therefore, interpretation maintains an interesting relation to the concept of agency. While internally representing reality, the mind does not operate ‘on behalf’ of reality; signs cannot be considered as agents, as they do not intentionally act, but instead are being acted on by the mind. Still, the character of intentionality, denoting the interpreting mind, is not only recursively self-fuelled but self-aimed. Hans-George Gadamer rethought “the traditional concept of hermeneutics as necessarily involving, not merely explication, but also application. In this respect, all interpretation, even of the past, is necessarily ‘prejudgmental’ in the sense that it is always oriented to present concerns and interests.” (Malpas, 2009) We previously defined computers as inscribed within a derived teleology. Having now highlighted self-aimed intentionality as the peculiarity of interpretation, we have evidence that computers are not capable of interpretation. However, it still makes sense to further investigate the analogies between human and machine cognition, as they appear to root into a similar dynamic of interaction.

In biosemiotics terms, “a sign is not the same thing as a piece of information. It is related to information but only becomes ‘information’ through an act of interpretation.” (Hoffmeyer, 2008) In the mind, each of the perceived signs evokes an entire net of concepts. When trying to explain and apply present concerns and interests to current experience, all the concepts thus evoked interact. Not only do the concepts recalled by a certain sign interact with concepts afferent to a different one, but signs and concepts actually affect each other, and as concepts change, so do the related signs. Forms of self-consciousness operate an open-ended process of redefining both themselves and their world of signs; their interaction is populated by signs that affect concepts, which in turn affect other signs and concepts. Finally, we can state that interpretation exceeds the self-contained teleology of what computers are today, as from their ‘what it is like’ perspectives signs do not exist, only information about their own current state does it. Unsurprisingly, current computers are not forms of self-consciousness. Nevertheless, these implications will help us in defining what both wakeful software and wakeful musical instruments are.

In Rowe’s definition of an interactive musical system, the term ‘musical’ exceeds the mere sonic phenomenon, as music is the result of an interpretation. In such a system, the presence of an interpreting

agent is implicit. For convenience, we shall use the following definition: ‘an interactive musical system is one whose behaviour changes in response to inputs, which at least one interpreting agent recognizes as musical.’ Will such an agent also consistently consider the system responses as being musical? Within art projects, in the present research, both users and audiences experiencing interactive music were frequently unable to interpret the sonic constructs, generated by such a system, as music. While computers treat the received stimuli as information, biological agents interpret such information as a network of signs. Such a discrepancy actually constitutes a structural obstruction, for living beings, in attributing meaning to actions or constructs that are generated by computers.

A step forward in finding a solution to this problem can be taken by considering biocommunication theory, which frames the interactions between subjects of the same species or between subjects of different species in terms of sign-exchanges occurring within a shared communicative commonality. “Inter-subjective interactions are characterised by reciprocal validity claims. To speak, make propositions and understand utterances does not function through private encoding process and subsequently a private decoding process, but a shared rule-governed sign-mediated reciprocal interaction. The shared competence of semiotic rules and the socialised linguistic competence to build correct sentences enable the interaction partners to understand identical meaning of utterances.” (Witzany, 2010) In order to circumvent the gap that we described above, the present study identifies specific structures of interrelation for living biological organism-machine interaction. These structures are defined as ‘bio-logics’; logics that mimic the informational mechanisms of living beings. These bio-logics are implemented as computer algorithms to improve such interactions. Without being recalled in such a way, these structures were nevertheless frequently adopted in computer science. Similarly, interactive software often incorporated these types of algorithms. The present research recognizes that such structures and instruments belong to the categories that we are here defining. However, their cataloguing exceeds our scope, which is instead to highlight the consistent significance of such theories and to offer classification of their nature, as a protocol for designing such interactivity; a set of procedures to be followed in designing living being-machine interaction.

Among the bio-logics, the present paper proposes salience to enable human beings to consistently attribute meaning to actions operated by a computer or to constructs that it generates, which they might not otherwise consider to be coherent signs within the context. Usage and improvement of salience-based mechanisms has recently been the focus of consistent research (i.e. as in the EPSRC project, aka Salience project), which offered the chance to successfully adopt such techniques for better modelling of cognition in computing. The Oxford English Dictionary defines the adjective ‘salient’ as ‘most noticeable or important’ and similarly, the psychologist William Crano identified salience, as a factor that informs the awareness of the perceiving subject about the effects of an attitude upon himself/herself. An interpreting agent selects salient information, in virtue of the self-aimed, explanatory and applicative character of interpretation itself and attributes a meaning to such information, identifying it as a sign. In the constructs or actions produced by computer programs, whereas the morphologies reflect salience, interpreting agents may notice such a salience and therefore, recognize the information as a sign.

Therefore, software can be described as wakeful, when sensing and responding in its multimodal ambient by defining salient morphologies to which living beings can attribute meaning, within the specific context. Such an attribution of meaning is actually consistent and not only occasional, as a communicative commonality is granted to these computers and living beings by the implementation of bio-logics. In such a framework, bio-logical algorithms format the information, as signs recognizable by living beings. Obviously, such a translation is only a simulation of an authentic process of interpretation. Still, regardless of whether the interpreting agents consider the machine to be a form of sentience, wakefulness,

self-consciousness, or just a convincing simulation, an act of communication can be actually established to a certain extent.

In communication, the resemblance of authenticity may be a valid surrogate for the real thing, as sets the necessary conditions for an eventual communication to actually occur; living beings recognize in salient interactions a logic that is proper to any life form. Alongside the approach offered by biocommunication theory, it is similarly possible to recall and extend Nagel's perspective in a direction offered by simulation theory, by which "human competence in predicting and explaining behaviour depends chiefly on a capacity for mental simulation." (Gordon, 1992) This theory deeply roots into the human capacity for empathy between subjects and "involves the imaginative method of projecting first personal experience, to achieve imaginative acquaintance with what it's like for the other." (Holton & Langton, 1998) In one of its latest formulations, simulation theory necessarily involves introspection, following the generation of a mental upshot for "detecting or determining the nature or character of that upshot." (Goldman, 2011) In humans, both a default tendency to empathy and a state of self-awareness are usually present. From one hand, an empathic feeling such as identification and eventually, even compassion, may arise after having recognized, in the interacting party, a characteristic that could denote life to a lower or higher degree: from unpredictability to reactivity, vulnerability, intentionality, or eventually, even humour. From the other hand, human beings may expose such characteristics when they do not imply intentionality, because of their sophisticated capacity of interpreting. Nevertheless, for humans, and possibly to a similar extent, for other living beings capable of self-consciousness, a simulation of intentionality may be more convincing, when it allows those to identify the trace of a sign within it. Forms of self-consciousness share an understanding of their world based on their subjective, experiential and only way to comprehend, and being aware of such an act. In direct proportion to the communicative commonality that they are sharing, these sophisticated living beings can consistently 'biocommunicate' its interpretation to each other, distinguishing between intentionality and a deterministic process. Sign exchanges constitute their mode of interacting (and communicating) within the multimodal ambient that they live in. Nevertheless, identifying within the responses of a computer a certain degree of intentionality, for however simulated and predetermined that can be, still may engage the interpreting agents into a convincing conversation with such a computer.

Any wakeful software is more than interactive, as it is more than sentient. It does not only have the capacity to eventually sense and respond; it can actually apply such a capacity in the mode in which the interpreting agents, populating its environment, interact. Such an instrument is wakeful, in the sense that those agents may repeatedly recognize its responses, as such. As content-related interactions involve the interpreting agents to interact in terms of sign exchange, wakeful software interacts with such an environment, in such terms. It is 'one that senses and responds to an environment with which it consistently interacts meaningfully.' Specifically for music, in play with a wakeful musical instrument, both user and audience may identify the generated sonic responses as salient information, which they may therefore interpret as a musical signs; for them, the interaction of the system is consistently musically meaningful. A wakeful musical instrument may be similarly defined as 'one that senses and responds to a musical environment with which it consistently interacts in a musical meaningful manner.'

MOBILITY INTO IMMOBILITY: DESIGNING NETWORKS

Luisa Paraguai

The text is concerned with the networks and flows of information and bodies, discussing other perceptions and movements to perform our everyday life and to comprehend the world. At the end, INmobility, an artwork in progress, is presented and concerns with the mobile technologies as other possibilities of people being temporarily “on the move”, questioning physical and temporal domains to propose narratives.

Fig 1. Visual narrative 1, 2011, Luisa Paraguai, photographic media.

Fig 2. Visual narrative 2, 2011, Luisa Paraguai, photographic media.

Fig 3. Visual narrative 3, 2011, Luisa Paraguai, photographic media.

The text is concerned with networks and flows of information and bodies, discussing other perceptions and configurations of movements to perform our everyday life, and so, to perceive and comprehend the world. “Movements often involves an embodied experience of the material and social modes of dwelling-in-motion,” [1] and we have sewing those organizations and systems upon physical and informational – data networks. Then, the reality can be understood as a negotiation process among different actual events, according to distinct protocols of communication and networks; it means the reality is understood as a dynamic process of flows.

Firstly, the people, technologies and space relationships are explored as possibilities of connections among different networks – as movements in physical spaces and/or as communication processes in digital and radio protocols. At the end, the project INmobility presented is concerned with the idea of technology as an agent to evoke other narrative dimensions to deal with the space and time, revealing different perspectives of reading and understanding the world.

Networks: Topologies Defined by Connections

Mobile communication, evoking characteristic ubiquity and accessibility, has permeated all domains of our everyday life. People have moved around actualizing different networks, physical locations and data nodes configuring a complex structure, programmed and self-configurable at the same time. “The diffusion of Internet, wireless communication, digital media and a variety of tools of social software has prompted the development of horizontal networks of interactive communication that connect local and global in chosen time.” [2] People have faced different patterns of arrangements, juxtaposed and superposed, trying to transcend the dominant logic of each network and to establish common and collaborative procedures. “Flows are streams of information between nodes, circulating through the channels of connection between nodes.” [3]

The mediated communication devices have configured a hybrid mode of existence, juxtaposing digital and physical domains simultaneously. That concept of hybrid space as a formal structure of those interconnections – visible configuration, has been considered quite important to apprehend the symbolic

and aesthetic perspectives of the reality. “The expression of social relationships, ultimately power relationships, that underlie the evolution of the multimodal communication system.” [4] The cultural dimension of that process, as a multilayered transformation of communication, can be defined by synchronic connections among several networks, with different protocols of communication; it means we have experienced the tension between the parallel development of a global culture and multiple local identities. We have to renegotiate space-time organizations as models of circulating in the world; it means we have to deal with different protocols of communication simultaneously as ‘to be on the move’ – to operate and produce within in-between spaces and times.

“Territorial behavior is a self–other boundary regulation mechanism that involves personalization of or marking of a place or object and communication that it is ‘owned’ by a person or a group.” [5] Nowadays, we have related to different forms of information systems – radio channels, mobile calls, GPS info, emails, text messages, skype sessions, facebook posts, twitter comments – tracing and tracking objects, locations and people. A specific perceptive and cognitive condition has addressed bodies-with-environments – physical and digital, to a specific set of performances. It means others within that system have known each person or object. Such systems, named as “flow architectures” [6] and “network society,” [7] have distributed economies, peoples, objects and activities, across the world. Their social structure is made up of networks that are powered by microelectronics-based information and communication technologies, improving on the characteristics of flexibility, scalability and portability. The apparently different domains of work, family, and social life becoming more networked, more similar to each other and more interdependent.

What is specific to our world is the extension and augmentation of the body and mind of human subjects in networks of interactions powered by micro-electronics-based, software-operated, communication technologies. These technologies are increasingly diffused throughout the entire realm of human activity by growing miniaturization and we may add portability. [8]

Technological and social organizational convergence has taken place between physical and technological systems and gradually has formed a new ambient, in which the ability to connect from wireless devices has become the predominant form of communication. The project INmobility is concerned with the meaning of materiality and those artefacts through the roles they play in different territorial networks. “In a world of networks, the ability to exercise control over others depends on two basic mechanisms: the ability to constitute networks, and to program/reprogram the networks in terms of the goals assigned to the networks; and the ability to connect and ensure the cooperation of different networks by sharing common goals and combining resources, while fending off competition from other networks by setting up strategic cooperation.” [9]

The main characteristic of wireless communication is not physical mobility but constant access and communication; it takes place because of the Internet potential structure of operation: a distributed network that has the possibility of combining distinct horizontal structures. Then, the mobile interfaces have connected those communication systems, not related and based on the Internet network protocol. It is a multimodal, “[...] also self-generated in content, self-directed in emission, and self-selected in reception by many who communicate with many” – “a mass self-communication.” [10]

We can stand a spatial structure that dynamically adapts to the communicational demands and necessities from own nodes; it means, for each new connection the network topology can be modified based on the existence of their nodes/users’ mobile phone and their abilities for communication. The attempt to comprehend and incorporate that operational network structure is to formalize a social shared space

as zones of fluxes, and not determined spaces of information distribution. Nowadays, it is necessary to comprehend mobility as the ability to move between different networks – physical and digital communication systems – that have as many dimensions as interconnections.

Automobility and Time-Space Relationships

The first attempt to reorganize public and social, spaces and accesses was made by the cars, extending where people could go to and hence what they are literally able to do. They set others flexible social patterns of commuting, family life, community, leisure, and the pleasures of movements and so on. “Machine space, or territory devoted primarily to the use of machines, shall be so designated when machines have priority over people in the use of territory. Automobile territory in modern American cities exemplifies the concept of machine space.” [11]

The car has reorganized in complex and heterogeneous ways the mobilities and socialities across significant distances and moments; it has created spatially stretched and time-compressed modes of people's moving and being encapsulated in a personal, cocooned, moving capsule – a bubble. “I suggest that there have been four characteristic modes of dwelling with regard to the car, what I term ‘inhabiting-unmade-roads’, ‘inhabiting-the-paved-road’, ‘inhabiting-the-car’, and ‘inhabiting-the-intelligent-car’.” [12] At first, the cars were open, not separated from the around sights, smells, and sounds – presented as the regular basis of commuting or even social life; in the second stage, the important was the tour than the destination – the performance of motor touring, the machine; in the third stage, the driver became a passive observer of the world, passing through the window – a refuge, a mobile privatization, in which the driver's body became fragmented and disciplined to the machine. The car can be thought as an extension of the senses so that the driver can feel its very contours, shape and relationship to that beyond its metallic skin. It is an everyday object and becomes a place to behave in a particular way in which, nowadays, people can organize a series of multiple activities, connecting to distant others through internet, mobile phone or radio.

“The car becomes a symbiotic extension of the driver own embodiedness.” [13] Automobility cannot divide spaces clearly – as work and home, leisure and work; it has produced lengthy commutes into and across the city. Then, cars have become a contemporaneous device, organizing possible complex models of social and cultural organizational structures to approach the urban landscape. Import us, the current instantaneous time involving the resynchronizations of the existent time-space paths. A shift to an individualistic timetabling of many moments or fragments of time – a personal clock-time upon the public timetable every time we drive. People have tried to sustain “coherent biographical narratives in the context of multiple choices filtered through abstract systems,” [14] and the project INmobility is an attempt to register those images and sounds.

The flexibility of movements is modeled by the temporal instance, producing multiple activities, spatially desynchronized from each other but integrated. It means, the traffic is a repetitive order of things independent of drivers whose actions compose it. People try to structure complex, fragile and contingent patterns of social life – self-created narratives – juggling fragments of time and activities. A network of individuals is connected through similarity of actions and intentions, and totally dependent on a social order.

“The difficulty we have in defining all associations in terms of networks is due to the prevalence of geography. It seems obvious that we can oppose proximity and connections. However, geographical proximity is the result of a science, geography, of a profession, geographers, of a practice, mapping system, measuring, triangulating. ... All definitions in terms of surface and territories come from our reading of maps drawn and filled in by geographers. Out of geographers and geography, ‘in between’ there own networks, there is no such a thing as proximity or a distance, which would not be defined by connectivity. The geographical notion is simply another connection to a grid defining a metrics and a scale. The notion of network helps us to lift the tyranny of geographers in defining space and offers us a notion which is neither social nor ‘real’ space, but simply associations.” [15]

INmobility: Texts and Textures of Everyday Life

People have performed their everyday life in metropolitan areas while organize constant attempts of virtualising the space-time relationship. In that text, we have brought the terms networks, cars and communication systems together to configure visual experience maps of moving as a collaborative and multitasking platform. The space and time relationships have been discussed articulating different protocols of communication and modes of distribution not coordinated. The INmobility project is concerned with the visibility of those temporary social networks, physical and digital, juxtaposed by synchronous live messages; the proposal of the narratives produced is to visualize our daily actions as dynamic collaborative networks.

Motion and emotion – the car was taken as a place to exercise the subjectivity, a private bubble in which experiences are released in unacceptable forms and gestures; it is understood as an enclosed space of control, inhabited in different ways and able to evoke new behaviors and gestures. Those body movements are understood as a polysemic representation affecting ways of sociability, formal and informal attitudes. Central to dwelling the car is the soundscape – different technologies can create sound spaces that are occupied by voices, music, sounds, and dialogues. Nowadays, the mobile technologies have proposed to the users other connections not proximal – from the intimate condition of driving to a participative way, to create their everyday routes.

Mobile technologies have set other possibilities of people being temporarily ‘on the move’, creating gaps and holes, other dimensions and domains. The ability of using those devices has demanded from users to comprehend and accommodate technologies on time and space. The ‘nine to five’ culture, in big cities as São Paulo, using mobile and GPS devices, can engender interspaces and reorganize physical arrangements, intertwining different space and time models. Audio and images narratives (figure 1, figure 2, figure 3) have been experimented, trying to track distinct networks and to map distinct social activities. The window and mirror images are explored as modes of recognition and presentation to others. Other perspectives and angles evoke a “fluid choreography,” [16] but still suggest an effective private space. From those visual narratives we can exercise parallel dimensions and to question the feeling of belonging to those urban spaces.

From the project we want to comprehend the tension between distinct materialities of the space and time relationship simultaneously operated by people through mobile devices. The intrinsic operational mode of the networks that conforms some informational patterns – computational and bodily, electromagnetic and spatial, has dislocated the usual understanding of shapes and spaces to propose other articulations. The blurred limits and the possibility of compounding physical spaces and informational contexts have evoked other dimensions for people’s interaction; the audiovisual narratives proposed have pointed out the mediated practices to create particular perspectives of those specific spaces. The perception and action relationship has presented itself as a phenomenological experience in which the individual, car and the ambient are included by media.

DIRECT TO VIDEO: STEPHEN BECK'S CAMERALESS TELEVISION

KRIS PAULSEN

This paper examines Stephen Beck's cameraless video synthesizers of the 1970s. Rather than using video as a camera-based mimetic medium, Beck directly manipulated the basic component of video – the electron. Video Synthesizers, I argue, propose an alternative understanding of video and its essential qualities. Synthetic video grounds itself in the materiality of the screen rather than the transparency of the image.

Fig 1. Stephen Beck at the Beck Direct Video Synthesizer, 1971, Stephen Beck, Digital image scan from original monochrome photograph, Copyright Stephen Beck.

Fig 2. Photograph of Two Video Weavings Still Frames, 1973, Stephen Beck, Video stills, Copyright Stephen Beck.

A live video camera pointed at its own monitor creates a vertiginous hall of mirrors in its feedback loop. The distance between the lens and the screen is simultaneously flattened and extended toward an ever-receding and ever-repeating horizon. The apparently automatic, realist codes of the video camera turn suddenly surreal by exploiting an inherent effect of the live medium. If one then tilts the camera, this loosened hold on representation slips completely away into dazzling abstraction. The monitor displays a dutched image of itself, but this image still contains in its echo the previous one – that of the upright monitor – and a temporal record of the movement. The image of a monitor turned perpendicularly in its own frame will swirl under the pulsating pressure of feedback. By slightly tampering with the aperture of the camera, the contrast, brightness, or focal distance one can completely divorce the image from any sign of reality. It pulls from the corners of the screen, and reconfigures into a tumbling pinwheel that grows more and more complex over time, creating morphing “mandalas” of electrons on the surface of the screen. These shapes, though free from the compulsive representation of the camera, are the “archetypical” [1] images of the video medium.

This live feed “mandala” effect is a simple means of divorcing the video camera and screen from the iconic and representational codes that usually govern it. Nam June Paik and Shua Abe exploited this and other effects to create their first video synthesizer at WGBH-Boston in 1969. Like Paik’s earliest television works, the Paik-Abe Synthesizer worked upon other images rather than literally synthesizing its own. For his first solo exhibition, 1963’s *Exposition of Music and Electronic Television* in Wuppertal, Germany, Paik altered the circuits in thirteen television sets, thereby determining the conditions under which the broadcast image could appear: images were reduced to thin lines, warbling waves, trembling circles, blurred tonal fields, and single points of pulsating light. Paik and Abe’s synthesizer similarly modified the video signal, but did so without altering the circuits of the television sets; their device manipulated the image in the studio then sent it out over the air. For the duration of the broadcast, the individual home receivers appeared to have been subject to a similar manhandling as Paik’s first sets. In 1970, hundreds of TVs in the Boston area appeared to be “broken” – or at least deranged – during Paik’s four-hour broadcast of *Video Commune: Beatles from Beginning to End*, the first on-air demonstration of the Paik-Abe Synthesizer. The Paik-Abe Synthesizer subjected live and recorded video images to a set of distorting processes that turned the visible world psychedelic and strange. Despite this abstract effect, the video image was still closely tied to the camera and its mimetic properties; the synthesizer needed the camera’s images to “seed” its manipulations and distortions.

Stephen Beck, like Paik, moved away from the representational effects of the video camera toward the abstract possibilities of a purely electronic medium. He, too, created his first synthesizer in the late 1960s, and later worked at a PBS research lab. Beck’s synthesizers, however, did away with the camera completely. They were, in his own words, “constructivist in nature, not distortionist.” Beck’s synthesizers were free from the camera’s mimetic representations.

Beck’s experimentation with electrical images began long before he had access to television set or a broadcast signal. While still an undergraduate at the University of Illinois at Champaign-Urbana, Beck invented a device he called “The Phosphotron.” It consisted of 10 pairs of goggles wired in parallel to a single oscillator. Beck would connect a group of his friends to the device for a “video séance,” during which the machine directed weak electrical current into the super-cutaneous surface around the eyes, causing a wild display of phosphenes to appear before the participants. They saw undulating colors, bright flashes of light, and floating shapes. The images hovered in space, but were not grounded in it. When Beck turned the machine up to about 20 hertz, the flows of light “broke into micro-textures very reminiscent of geometric, quasi-crystal patterns found in Islamic, Byzantine, and Ottoman art.” [2] The

device brought to collective vision a set of non-objective, archetypal images using neither camera nor screen.

The young artist and engineer's desire to capture and communicate the fleeting, intangible, immaterial shapes of phosphenes and hypnagogic imagery led him develop a series of direct, that is, cameraless, video synthesizers in the late 1960s and early 1970s. The National Center for Experiments in Television (NCET) invited Beck to California to become a resident artist in their studio after hearing about his first analog synthesizer, the Video Synthesis Instrument Number Zero (VSI#0) (1969). The center was an experimental video division of KQED public television in San Francisco that specifically encouraged the production and broadcast of non-traditional forms of television. There he created two other synthesizers, The Beck Direct Video Synthesizer (1970-1971) and his first digital synthesizer, the Video Weaver (1973).

At 7:30 pm on 19 May 1972, Stephen Beck performed the Beck Direct Video Synthesizer live on KQED-San Francisco. According to Beck, it was the first – and perhaps only – live broadcast from a direct video synthesizer. [3] Beck's historical performance took place as part of KQED's news program, *SCAN*. Reporter Joe Russin interviewed Beck at the controls to give the viewers some context for what would follow. The young, longhaired artist explained, roughly, how the synthesizer worked while Russin, chin in hand, pondered Beck's curious answers. The synthesizer, Beck explained, "generates electronic signals which excite the television set to create light to happen where I want it to." Video, he provocatively offered, does not need to be "pictures of things." While the two men talked, Beck manipulated the synthesizer's controls, producing a rapid series of random patterns, graphic figures, and iconic images. The machine was a beast: color monitors and hulking switchboards stitched together with bright loops of yellow cable. [Fig. 1] The physical complexity of the synthesizer, with its exposed wiring and tangled connections, stood in sharp contrast with Beck's easy, graceful manipulation of the image. Despite Russin's contextual framing of the synthesizer, KQED's viewers frantically called into the station during the performance to accuse and compliment the broadcasters for "breaking" their televisions. [4] Yusef Lateef's music accompanied Beck's fluid, undulating color forms. The music was significant: not only did it link Beck's visual compositions with the improvisational form of jazz, the synchronization of visual and musical elements indicated, beyond a doubt, that the television wasn't "broken;" it was merely behaving in a way that seemed incompatible with its typical behavior and the conventional forms of broadcast television.

NCET went to great lengths to publicize and popularize their prodigy's invention and the growing field of synthesized video. Brice Howard, the Center's director, produced a series of "Electronic Notebooks," aimed at both distributing work by the Center's artists, and educating the general public about how to actually see the television rather than imagine that they were seeing through it. The series featured Beck on its inaugural episode. "Electronic Notebook No. 1: Video Synthesis" (1973) paired Beck on the Beck Direct Video Synthesizer with musician Warner Jepson playing the Buchla Audio Synthesizer. The episode opens on the two artists, side by side, at their synthesizers as a narrator compares the more familiar audio synthesizer to the processes of Beck's machine: both machines conjure "forms, textures, and colors" from electronic signals. The description links synesthesia to synthesis, as do the titles of the pieces that followed: *Illuminated Music 2* and *Illuminated Music 3*.

Illuminated Music 2 begins with a cut from footage of the artists to a blank, black screen. Two bright rectangular dots appear in the center, along the CRT's horizontal axis. The two quickly split into four; each dot and its double slide vertically away from each other and then loop into the center of the screen, and then disappear. They glide across the surface of the television, tracing a clear path without ever forming a proper image or shape. The pattern repeats twice over, and then quickly grows more complex: rather

than disappearing into the screen's central fold, the dots double and circle each other in a juggling pattern. The left side mirrors the right, only slightly out of sync. The slowly dancing points of light then quickly replicate themselves, extending in long chains to the center point of the screen. For a moment, the discrete dots take the form of an octopus, each long leg moving in a manner that is, at once, both natural and magical. The component parts of each undulating tentacle become independent fill the screen with a kinetic yet orderly field of static. The buzzing dots then melt into smooth airbrushed forms. By beginning with discrete dots - units of light - Beck slowly reveals the screen as, simply, a set of potential coordinates in space and time. What one sees is not an object or a representation or an image, per se, but the excited, ever changing surface of the screen; this is video freed from the camera.

From single points of light, the Beck Direct Video Synthesizer made the television screen and its basic operations visible and intelligible. One can no longer look "through" it as if it were a window to the moving image on the other side. One sees the screen for what it is: a flat field of points, a surface. In *Illuminated Music 2* the most basic unit of the electronic image pulsed and morphed into a dazzling and eccentric series of "archetypical" images – mandalas, geometric tessellations, phosphene flares, and hovering afterimages.

Beck's next synthesizer, the Video Weaver, brought into view another formal property of the video image, the horizontal and vertical scroll of the monitor's electron gun. Again moving away from the camera and the representational forms that it produces, Beck shifted the viewer's attention to the movements that make up the video image, rather than its component parts. Through Beck's new machine, screen's horizontal and vertical lines become the warp and the weft of a weaver's loom. The graphic patterns are in constant motion as they scroll across the screen. In *Video Weavings* (1973) [Fig. 2], Beck cycles through a series of traditional textile patterns: diamonds, chevrons, and argyles slide seamlessly into complex Hopi, Navajo, and Shaker designs. Beck's digital synthesizer analogizes the ancient technology to the new one: each creates an image built of lines read one by one. The weaver's thread becomes Beck's electron beam. Through the metaphor of weaving, Beck further extends video's point-by-point, line-by-line electronic logic to that of the computer: the Video Weaver is the descendent of Jacquard's loom. Joseph Marie Jacquard's 1801 invention, with its punch cards and prefigured sequences, anticipated the development of computer hardware and programming. Beck's weaver picks up this historical thread, and connects early video to generative and computational art. [5]

The non-representational, computational character of synthesizer video sits in an uneasy relationship to the history of video art. In the mid 1970s, video was just beginning to be theorized and historicized. In 1976 Rosalind Krauss famously condemned video art as narcissistic and unconcerned with the formal, "reflexive" investigations of serious artists and critics. Video, rather, is "reflective," that is, it acts as a mirror transmitting live, representational images, usually of the artist or viewer. According to Krauss, the self-obsession evident in early video art, however, is indicative to the medium and narcissistic video artists accidentally model the formal structure of video by obsessively using the device to record and respond to their own images. If video is a "medium," Krauss ventures, it is in the psychological rather than formal sense of the word – "telepathy, extra-sensory perception, and communication with an after-life." [6]

Krauss's critique of early video does not take up the non-objective, non-mirroring work by Paik, Beck, and the other synthesizer artists. Instead it centers on a set of artists who had come to video after making their names in other media. The history of video art has largely followed Krauss's lead and bracketed synthesized video (with the exception of Paik's work) as a footnote to the larger history of artists' video, [7] despite its important role in the development of the genre and its enormous impact on future of the

media and technology. As early as 1974, Artforum editor, Robert Pincus-Witten cast them out of the discussion of video art precisely for being formalists and for being unconcerned with the representational image. At the Museum of Modern Art's conference on the state of video art, "Open Circuits: An International Conference on the Future of Television" (1974), an early academic assessment of video art, Pincus-Witten argued that the work of synthesizer artists "was deficient precisely because it was linked to and perpetuated the outmoded clichés of Modernist Pictorialism." Video, for the critic, was an inherently "reproductive recording medium" that "must always engage narrative content." The only achievement of the synthesizer artists, he claims, was the invention of the various devices. [8]

Non-representational, ephemeral, often unrecorded and cameraless, synthetic video found itself in a difficult position in relationship to criticism in the 1970s. In Krauss's and Pincus-Witten's accounts, video is a camera-driven, "reproductive" medium. Synthesizer video, then, simultaneously exposed a nature that seemed too inherently close to the waning principles of modernism, and in its experimental agenda it exposed most of what appeared to be the essential trappings of video – the camera, representation, tape – as not necessarily or inherently part of the medium. In doing so, synthesizer video surprisingly brings together the reflective and reflexive poles of Krauss's argument. Feedback, according to Beck, is "the imagery that results from the television set in a self-meditative state. Input is focused on output, its eye focuses on its vision, and in this meditative state it creates a specific graphic imagery." [9] When the camera looks at itself, it doesn't see as Krauss's "narcissistic" video artists do. What it sees is an ever-changing series of non-reflective images, variations on its own essential forms. In video, mandalas – those images that aim for unity and completeness through meditation – expose the screen as complete within itself. Beck's work extends this path of essential yet non-representational video forms to the screen without aid of the camera. Here, in the realm of pure video, Beck separates the image from the screen, just as phosphenes are visions separate from the eye. The video medium is at once, formal and reflexive, and at the same time "extra-sensory" and "psychological."

Clearly, Beck's synthesizer works call attention to the reflexive qualities of the video screen. The formalism that Pincus-Witten condemns seemed to destabilize the what appeared to be the very nature of television and video and in doing so, severed it from a clear lineage with representational media and mass media, such as photography and film – and even conventional TV – and established a new trajectory that linked it more closely to computer graphics and to future forms, such as video games and generative arts. Beginning with the feedback mandala, artists like Beck discovered how the camera's ability to transmit live, indexical, images could be used to free it and video screen to make imagery that was, at once, both abstract and deeply familiar. When divorced from its compulsion to mirror and capture the physical, visible world, video laid bare a parallel world of archetypical, geometric, non-objective images. Mimesis was just one function of video, not its essential, medium-specific quality. Rather than looking at the kinds of images a camera could capture, they sought out those that the screen seemed specifically able to produce. This meant seeing past the narcissistic seductions of the representational image, and looking at the device for what it was at base – a single electronic dot skating across the rasterized surface of a magnetic screen.

TRANSCENDING INTO THE VIRTUAL: PRESENCE PROGNOSTICATIONS AND THE RE-CALIBRATION OF TELEMATIC ART

ELLEN PEARLMAN

Telematic Art is artistic collaboration over robust 1gigabyte fiber optic research networks. This paper explores recent experiments in telematics with 3D Virtual worlds, improvised performance, motion capture suits, spoken word, video art, live and pre-recorded dance, VDMX VJ effects, MAX/MSP/Jitter and various music and sound programs with live audiences and on-line performances.

Fig 1. The dancer's outline of herself in the "Nuclear Sweet" video, produced when her motion became sound and the sound became dark pixels of herself mixed into the video sent through a network connection.

Fig 2. Text poem in white, four video clips projected on boxes, Actor reading on Skype, motion capture studio with dancer on grid from Hong Kong for Syneme Summer I.

Fig 3. Pixellation, chroma and drawing (blue lines) manipulated by finger bending in "Here and There".

The Wonder of the Ancestral – In a Post Modern Kind of Way

Telematic Art originated from developments in computer art, hardware and networking technologies based on algorithmic and mathematical art. This has enabled new forms of representation and interactivity in group authored artworks over networks. For the most part sound, or sonic arts has formed the basis of development for many experiments at Syneme Labs based in Calgary, Canada. New media with each new iteration tends to develop and embellish the framework of older mediums it references as a kind of augmented proxy. In that sense what Syneme has done resembles the early experiments with the telephone when Alexander Graham Bell uttered his famous sobriquet, “Watson, can you hear me?” Initial connectivity for Syneme focused on uncompressed audio over high speed fiber optic research networks, especially but not limited to IpV6. [1]

The first piece of computer-based art appeared in 1951 when John Whitney used left over bits from defunct analogue computational devices. Most technology now in vogue, including “3D goggles, network art, computer-generated choreography, bio-computer interfaces, expert systems, robot art, ... were already common currency in the 1960s and 1970s.” [2] Roy Ascott in his essay “Is There Love In The Telematic Embrace” [3] clearly understood the implications of the confluence of “video, sound synthesis, (and) remote-sensing. He defined telematics as “Computer-mediated communications networking involving telephone, cable, and satellite links between geographically dispersed individuals and institutions that are interfaced to data-processing systems, remote sensing devices, and capacious data storage banks.” The observer/participant and the system they are working within are in a constant state of change and even instability because the content is electronic and digital until it reassembles itself as one of a number of different art forms. The art object changes into a “cultural communication system.” Telematic communication “extends the gaze, transcends the body, (and) amplifies the mind into unpredictable configurations of thought and creativity.” [4]

There were few instances of these developments; Kit Galloway and Sherrie Rabinowitz's ground breaking 1977 *Satellite Art Projects*, Roy Ascott's clever 1980 *Terminal Art*, and at ISEA'94 in Helsinki, Paul Sermon's *Telematic Vision*. It showed a video camera recording events on two separate couches. A person sat on a couch in each location. On a monitor that mixed the images both individuals could see themselves in virtual space sitting together, and could interact and respond to one another. Since this paper is not on the history of digital or telematic art, these examples are just a tiny slice of the work that has preceded these investigations. Not all Syneme performances and concerts in the past two years are mentioned, just those that this author participated in.

In The Beginning Was Sound: A Sense Of Urgency – Making the Connection

2009 - OCTOBER

On October 27, 2009 I sat in the auditorium at the China Electronic Music Center (CEMC) at China's Central Conservatory of Music in Beijing. This was the first time that the Central Conservatory of Music used its new high speed fibre optic connection to initiate a telematic concert with Canada. Bruce Gremo's played *Calgary Interventions* on his Cilia flute controller using MaxMSP. For improvisation he took a soprano saxophone signal from Jeremy Brown in Calgary and let three continuous streams from that data control his output. I watched Bruce on stage, and saw Jeremy projected on a screen overhead. An image

of a whirling graphic appeared on another projection screen. This was the first telematic concert I had seen and I secretly hoped someone would jump out of the screens and do something on the stage. [5]

The technical obstacles to this concert, which included other musical compositions between China and Canada, were formidable. Before any of it could occur, a fiber optic line had to be taken from a Beijing research university and physically cabled over to the music conservatory. The Jack OS software that enabled the connectivity needed to be implemented, tested and stabilized. Wang Ke (Haku) a Beijing music student and programmer modified the original Jacktrip program to make it compatible with Ipv6.

2010 - JANUARY

In January, 2010 I began my studies in telematic art at the University of Calgary with the Canada Research Chair in Telemedia Arts, Ken Fields. Ken had laid down the fiber optic line in Beijing and set up that first concert. By the end of January I was working with other students on the NetTets 2010 Happening Festival facilitating a concert between the Central Conservatory of Music, China, Tavel Arts Technology Research Center, Indiana University Purdue and the Yong Siew Toh Conservatory of Music and the Arts and Creativity Lab, Interactive and Digital Media Institute of the National University of Singapore. A percussionist played live time at the Rosza Theater at the University of Calgary watching musicians on a projection screen in Singapore, Beijing and Indiana. Everyone could see one another and play together. The average latency of sound between node points was about 300 milliseconds. This setup had been accomplished using JackTrip audio software and a Lifesize video conferencing system that compressed the video signal.

It was thrilling we made the connections work between four timezones and everyone played together in front of a live audience. [6] This proved that four countries could play a concert together live time, and was an important next step for our research.

You Can See Me - Now What?

2010 APRIL

On April 24th Syneme Labs presented a 15 minute performance at the Indiana Intermedia Festival, a production of the Donald Tavel Arts Technology Research Center, Indiana University Purdue University Indianapolis. This performance consisted of Syneme Labs, musicians at the Tavel Arts Center and a group of 3D artist at the HR School of Fine Arts in Bloomington. [7] The artists 3D world made in 3Dvia Player was sent to Syneme Labs from Indiana utilizing the LifeSize and Tandnburg systems, and projected onto our right most wall. At various times Syneme had its own 3D world created in Maya3D projected onto the left wall. A dancer moved back and forth between the two worlds, and a third image on right projected what our studio camera was recording. This image was sent to Indiana for projection on stage at their Tavel Arts Center. At different times pre-recorded effects from VDMX, a VJ software were projected onto the dancer. Pre-recorded music in the Syneme lab also played in the background. All of this was sent back over the network to Indiana where three sets of live images were projected while musicians on stage improvised and played their own scores.

During the concert Syneme could not see the live stage in Indiana, though Indiana could see whatever images Syneme chose to send through its live camera feed. We were able to shift back and forth between

the 3D virtual worlds and the VDMX projected worlds by using the Lifesize conferencing system software. By introducing a robust visual interface and a life dancer interactivity and presence factors were greatly enhanced.

JULY 2010

The First Annual Syneme Summer Institute in Telematic Art was launched with participants from Calgary Canada, Beijing China, Bournemouth United Kingdom, Waikato New Zealand and Indiana Purdue, USA, using a variety of technologies and means to project video, poetics, motion and sound into the studio. One person read over Skype excerpts from the Bible and Chairman Mao's Book of Quotations. These excerpts were translated into 85 English letters aligned equidistantly without spaces between words or punctuation, as they would be in classical Chinese and ancient Hebrew. The visual texts were displayed and read by viewers. The text was projected onto a horizontal square. Underneath the text, projected onto white vertical boxes were videos that had been FTP'ed from Hong Kong and projected through a MAX/MSP VPT (Video Projection Tool) patch. On the right was a live animation of a dancer in a motion capture suit performing on a green grid. Our aim was to have the motion of the dancer control simple parameters in the video such as on/off or brightness, or saturation. Music originated from New Zealand and Calgary. [8]

There was a time lag between the movements of the dancer in Hong Kong and the movements of the dancer appearing on the grid screen in Calgary, but it did not affect the performance.

There were many technical issues to resolve. Since the Summer Institute lasted only three weeks, the deployment of Hong Kong PolyU's staff including the HARNET, the Hong Kong fibre optic backbone required constant debugging. A programmer in Beijing opened up the SDK of the motion capture system to change its parameters. The frame rate of motion capture had to be reset to work at the unusual rate of 60 frames per second so the x, y, z coordinates of the animated motion capture software could be streamed to Calgary.

DECEMBER 2010

In December Syneme facilitated ResoNations, Arts for Peace of the UN-NGO WAFUNI. Renowned musicians from New York, Beijing and China participated. Not all partners were on IPv6, some were on IPv4, so Syneme acted as the switching station in routing network information between these countries. [9] This concert resembled the January 2010 NetTets concert because it connected three disparate locations together for a music performance

JANUARY 2011

On January 29th, 2011 at the NetTets2011 Festival I premiered "Nuclear Sweet" [10] a telematic performance based on formerly classified videos of nuclear explosions from the 1940's-60's that were filmed and narrated by a cadre of Hollywood elite sworn to decades of secrecy. This distributed performance event worked with a live dancer who, through movement was able to generate and manipulate sound in real-time with the interplay of imagery. The dancer's movements were captured in the camera and processed with a motion capture function in Isadora Software. The velocity of her movement was then sent over the network to a MAX/MSP granulator patch. At various times in the performance the sound

or pitch from the granulator patch was routed over the network back into the videos playing behind her, disrupting the pixellation with a ghost-like image of her form appearing in the video. Simultaneously music was sent over the network live time from Indiana U.S., by a musician who was watching the performance via a live video feed. His audio connection was over JackTrip.

APRIL 2011

On April 21, I worked on the visual component of "Here and There," [11] a musical piece for ham radio written by Stuart Saunder Smith 30 years ago. For this piece I made a flex sensor glove that was connected to an Arduino board and worked with effects in MAX/MSP/Jitter. These effects consisted of changing the pixellation and brightness, contrast and saturation of an image by moving my fingers. I could also blend multiple images and awkwardly draw a crooked line across the screen, then erase the line with a flick of one finger. These images were sent over the network using Skype and projected on a screen in front of a live audience. They were manipulated in response to the live time music in Indiana. These crude effects proved live time manipulation of a broadcast image could be sent over the network in response to music and other stimuli.

SYNEME SUMMER INSTITUTE II

Returning to Hong Kong for Syneme Summer II, I created "I Move In Decades," a telematic performance about the tenth year anniversary of the attack on the World Trade Towers. Using the talents of professional dancers, musicians and video artists, it built on the research done in Syneme Summer I of converting motion capture data to OSC. For this iteration dancers were rigorously mapped with their x, y, z coordinates using specific trigger points on the wrist, elbow and ankle. A clear range of motion was codified. The data was successfully converted to OSC. However, the MAX/MSP patch was not ready to be used in time for the performance, so the live time OSC data was stored. An asynchronous use of it will be used with a MAX/MSP patch. [12]

BODYCAD: CREATIVE ARCHITECTURAL DESIGN THROUGH DIGITAL RE-EMBODIMENT

BANU PEKOL

Combining architectural theories with insight from courses/workshops taught to architects on embodied design, this paper deals with the question of how the use of digital media in architectural design can propose creative conditions for movement and how movement creates similar openings for architecture. It demonstrates the need for the creation of an informed architecture inviting movement through relational architectural interventions.

Architecture incorporates the possibility of action, which is naturally tied to a bodily reaction. Any structure that aims to be evocative should go beyond the merely visual. Unsurprisingly, the same can be said about choreography. This paper aims to demonstrate how architectural education can be enriched through digital spatial analysis tools which stem from the need for an enhanced bodily awareness for architects. The projects which this paper refers to are all concerned with deconstructing space such that it is experienced differently: through the use of the graphic programming environment Isadora, the structure provides a reassessment of itself. Methodologies for assessing the impact of movement on the perception and cognition of architecture have yet to be developed fully. The experience of space is closely tied to what it means to be a subject and with the constructions of subjectivity. This paper argues that both architecture and dance are about experiencing and visualizing space, which furthermore shapes the creativity as well of subjectivity of architects (or even, dancers).

Architecture is a dependent discipline. Yet also, architecture, as a profession and practice, does everything to resist that very dependency. This means that architecture is influenced by external forces from the design stage to the construction and even occupation stage. Thus, even if the architect has internal processes of her own, it is the external forces that shape the architecture itself. From this dichotomy arises a gap, which this paper engages with by incorporating the body and movement into architectural creation. Beginning as a consequence of the Beaux-Arts system, architecture has retreated into an exclusive and self-referential world. Today, even if the architectural outcomes in schools look radically different, the processes and methods used to achieve these outcomes are analogous. In some schools, conventional software is put aside for new algorithms generated by the students, which actually all follow a similar value system. [1] Progress seems to be represented by technology combined with aesthetics, using the newest technologies, forms and surfaces available. This is mainly due to scrupulous attention being paid to winning the client or audience, using various visual ploys and tactics. Also, the inevitable use of photographs in publications shifts our attention from architecture as a spatial whole, to the representation of it. Further, as curriculum requirements become standardized, more technical and even administrative skills being expected from an architecture graduate.

Architectural Theory and Embodiment

Kant defines space as an “a priori representation which underlies all our outer intuitions.” [2] The space he explains is mostly derived from inside the subject, rather than external factors. This is a notion which implies that space is created from within the individual, a theory has been proven scientifically through

evidence that a certain area within the human parahippocampal cortex is more active in response to layout of space, as compared to using only objects as a reference point. [3]

As the German philosopher Johannes Volkelt argued in the late 1870's, the composition of a particular space can only be explained through movement and we must participate in this *emotion of movement* in order to understand it aesthetically. Such participation will provide the viewer with a more holistic experience of the building. Even though the importance of space is acknowledged in architectural historical literature (always within the limits of a privileged historiography), this is not extended to movement through space, and how the body responds to space.

In the second half of the 20th century, J. J. Gibson challenged the concept of visual perception and demonstrated that it is part of a perceptual system which actively involves locomotor movement. J.J. Gibson's reversal of sensory apparatus with types of environmental information the body deals with can similarly be adapted to this case. The function of architecture as stable and inert, and the body as a walking organism can be applied in such a way that architecture is regarded as the information that one can interact with, and accordingly the body will be forced to acknowledge the space created by the architecture: a new language, or inventory for movement will be created.

Heidegger's concept of *ent-fernung*—where one distances herself not according to physical distances but to what is important to her—is also useful to elaborate what is aimed at in this project. [4] In this way, physical priorities are played down and factors such as the perceptual and social can be engaged with much more efficiently. Space becomes a vessel for possibilities (social, cultural, perceptual), merging the body phenomenal and body politic.

Lefebvre, in *The Production of Space*, argues that space is produced by multiple social forces which he categorizes into the perceived, conceived and lived. This argument is useful to show that architectural design is one aspect of spatial production, and that the other agencies are as valid, if not more, than architecture. [5]

A work of architecture, even if its outer walls remain put, has within it spaces that can change or move. The “mobility of building and within building is one possible idea of Deleuzian thought that might be of tremendous value in architecture.” [6] Building is generally understood as the movement of materials for the final stabilization of a structure. Yet the activity of building should also be seen as a method of creating, opening and unfolding spaces. This means that a building can allow new methods of mobility, movement and change.

Why should a building built by humans who inhabit their physical bodies not be influenced in a more informed way by these bodies? The corporeal presence of a building is thus both an apodictic part of design, and also an element of architecture that is not as removed from the architect as, for example, the infrastructure. Architects should feel free to seek ideological inspiration beyond their field of discourse. Such inspiration and expressive potential can then be used not only for conceptual propositions, but also physical applications. In turn, this will bring closer the architect and architecture, the designer and the design.

Movement and Architecture

Defining architecture through a field not normally and necessarily perceived to be related to it allows us to engage in a dialogue with architecture which would otherwise have not been possible. Architecture and movement can be studied together, but for what use? The means of architecture are basically set forth by our capabilities to make and sense physical distinctions in space. Movement/dance is not a part of architectural education, or vice versa. Yet both disciplines can borrow from each other in their process of creation. For example, both dance and architecture organize space. However, therein lies a nuance: dance de-stabilizes the space for the in stasis spectator, while architecture reinforces the space with factors such as gravity and functional necessities. Architecture can be considered as the main, dominant discourse for structuring space, and dance can be considered the main discourse for 'feeling around' space. A dancer can articulate space in a way much different than an architect. If architecture is a "set of practices, techniques and skills" then dance can provide a further set of skills or techniques to it.

Our bodies as psycho-sensorial systems are capable of picking up and sending haptic signals and responses. Architecture is capable of creating a bodily response and participation; however few buildings succeed in doing so. Since all buildings are created with the human mind, it is first and foremost the mind that should work with the body to become aware that architecture –which embodies the possibility bodily interaction–, will enrich the human experience. The interaction may not be tactile; it can be imagined as well, by envisioning flying over and under buttresses, gliding along curved walls or soaring upward through stairwells. An initial disorientation is necessary to then become aware of the spatial relationship of our potential movements with the architecture itself.

As Le Corbusier says, architects live in the extraordinary world of the acrobat. [7] Dance and architecture both frame, articulate, structure, give significance, relate, separate and unify, facilitate and prohibit. Mostly, they do this through logic of visualization stemming from notions of perspective, and thus viewing the world in a Cartesian way. If we consider the logic of visualization, we understand that seeing things from such a particular perspective or viewpoint locates the viewer and affects their sense of subjectivity. But dance and architecture also can disrupt this logic by lessening the distinction between buildings and space, inside and outside. Distinctions between warm and cold, still or windy air, scents and sounds, the feel of various surfaces are all components of architectural experience that can only be enhanced through being exposed to and creating such sensational experiments.

The Graham technique in modern dance uses exercises based on the haptic experience of space. The expression of 'feeling the space' is almost literal, as dancers who practice this technique pull and push the space around them to give meaning to their movements. Rudolf Laban's dance notation is another attempt to define space through the movements of the body using geometric planes.

Digital Tools and Architectural Embodiment

Choreographers have been working with digital platforms since the 1990's in order to pass on their choreographic theories and practices to their future company members, or interested dance-enthusiasts. The most well known is William Forsythe, who has worked with researchers and artists from varied fields for his award-winning online dance notation 'Synchronous Objects, for One Flat Thing Reproduced'. His works are interesting because they are able to convey his choreographic logic not only to dancers, but also non-arts specialists such as cognitive scientists.

Such open-ended digital educational tools are becoming ever more popular. Architectural education has been using digital platforms mainly for translating the sketched image into perfectly calibrated drawings, and easily manipulating it once on screen. Even with 3D renders of architecture, the fact that the viewer's body is motionless while looking at a flat screen remains unchanged.

The gap between the internal processes of the architect and the external forces that shape the architecture can be studied through digital technologies. Architecture is taken here in the context not only of the built environment but in the multiple groundings and environments for movement. Architecture does not necessarily mean the practice of building; the intelligence from architectural education can be applied in various ways. This conclusion that models used in design science are metaphors which convey their meaning by way of a hermeneutical understanding has been exemplified in multiple studies. [8]

"Aesthetic and cultural practices are peculiarly susceptible to the changing experience of space and time precisely because they entail the construction of spatial representations and artefacts out of the flow of human experience." [9] The outcomes of working with architecture and dance not only benefit the digital representation of space and architecture; they redefine a movement vocabulary. When walking on the ground, one notices a small inclination, or any irregularity. The muscles and balance, adapting to the surface, automatically compensate this. When using a virtual model, such automatic reflexes do not exist at first; they must all be learned and experimented with, to find the ideal response. The walls, although virtual, represent obstacles, and since the voyage is undertaken not just by walking on the floor, the ceiling, walls, windows, doors and columns all have as much importance as the floor. Architectural elements gain a new meaning, and features such as arches which used to be structural and decorative, now interact with the inhabitant.

The idea that aesthetic perception of architecture should be enriched with the inclusion and application of full spatial comprehension forms the basis of this paper. Since Kurt Gödel, it has been confirmed that no system of logic can contain its own explanations: a given system is always built upon axioms which are subject to further analysis. The form of one system becomes the content of the next higher system, and so on. So, the form of the building is the content of our interaction with it. You cannot interact with a façade. The project similarly is a work on oneself, on one's own interpretation on how one sees things etc.

The following examples aim to illustrate how such participation can be developed, and how the body can be used interactively with the space/architecture around the architect in training so that architecture becomes an expression of life, rather than an evasion of it.

ARCHITECTURAL BODIES

In the workshop titled *Architectural Bodies: Experiments on Gestures*, conducted by the author in Summer 2011, participants were led through a series of intellectual, cognitive, and physical exercises that seek to question the relationship between gestures and architectural spaces. Both the technical as well as the creative processes underlying this workshop allowed the participants to experiment with their own perception of 'natural gestures' as well as creation of 'spatial gestures'. For the workshop, using the graphic programming environment Isadora, a computer programme that analyzes real-time gestures and their interaction with various architectural settings was prepared. Each participant formed her own "spatial gesture" by choosing a particular pre-recorded space and through the computer program output constructed a physical response to the space with her own body.

This workshop aimed to demonstrate how spaces condition particular gestures, and how gestures are inherent even in activities where only one person is involved. The translation of gestures into architectural images provide an exciting yet challenging insight into how dominant jests can be re-evaluated within the context of space-creation. Architecture students, who are used to working with AutoCAD, Rhino and other computerized architectural programs, when faced with their body in space, acknowledged that their bodies in space have no relation to the straight lines or geometric shapes which they are accustomed to working with. In the workshop, the real and the virtual imply each other continuously. Through the experiences gained from virtual interactivity, the sequence in which the content is structured will not –as is customary– stay linearly organized, accessed and unchanged.

The workshop allowed the participants to acknowledge that gestures can not only be understood as representing body-images, as the movements of the participants were driven by proprioception rather than architectural design principles taught in their classes. This fact is reminiscent of Agamben's argument that "If dance is a gesture, it is so, rather, because it is nothing more than the endurance and the exhibition of the media character of corporal movements. The gesture is the exhibition of mediality: it is the process of making a means visible as such". [10]

One other program prepared for the workshop connects the limbs of the participant to a 3D CAD mode, using sensors. The spatial limits of the building make the voyager move in a certain way, completing the interactive cycle. The space suggests a particular way of movement to the voyager and with this suggestion it will reveal that which it is harmonious with, and anything that prevents it will seem out of place. This can then be linked to the design problematics in architecture, pre-construction analysis, or to different analyses of theories of architectural analysis. The user of the program must always try to think of and use 'form' in its full spatial completeness. In order to do this, she stops prioritizing the façade. This is akin to when in dance, the dancers are constantly reminded to feel their centre and move through the manipulation of the centre. Such a centre of intention can be formed in architectural movement research. Thus, through our interaction with the work and our decisions to move in a particular way throughout this interaction, we meet ourselves in the work.

The workshop also draws from Paul Schilder's concept of "body image/body phantom" which is a neuropsychological mapping of the body which refers to the inner image of one's outer, physical appearance. The graphics, formed by the workshop participant's bodies on the architectural videos provided an alternative body image. By internalizing the external to the body (the architecture, in this case) into her corporeal activities, the participant began to adapt her body to the context.

BODY AND SPACE IN ARCHITECTURE

An undergraduate course titled *Body and Space in Architecture* created and taught at the Mimar Sinan Fine Arts University's Faculty of Architecture by the author, focused architecture undergraduate students on architecture and embodied design. The majority of students had difficulty tearing themselves away from the obsession with producing visually impressive work. Once they got the hang of the subject, they began seeing the body in every aspect of architecture. After completing their end-of-year project, the students came back with results that they confessed they had not expected, with comments such as realising that functions were not the same as desires in architecture. This implies that their education which included courses on ergonomics was in need of a supplementary module which demonstrated the versatility of the body in architecture.

Conclusion

The theoretical background along with the examples from educational practice complete circle back to William Forsythe, whose understanding of space is “an inclusive concept that even integrates the interior of the bodies, breath, and most essentially proprioception; all of these factors become interfaces for artistic response and creation.” [11] Forsythe’s CD–Rom ‘Improvisation Technologies’ applied geometries of objects in the space around the dancer onto the dancer’s body. The digital practices where body becomes space itself can be applied to architecture students who will then stop relying on their auto–pilot (or rather, auto–architect), and engage in a more intimate and visceral manner with their design concepts. Heidegger’s suggestion that we live in the space opened up and revealed by technology rings true once more, in this context. [12]

Architecture is generally experienced by dwelling in it. August Schmarsow ‘s term *Raumgefühl* (sense of space), rather than *Formgefühl* (loosely translated as sense of form) is what should guide the design approach. The architectural experience of a space should be extended from only accepting it as a dwelling to a more aggressive, seeking approach to architectural forms with the use of new psychophysical coordinates. Architectural design can become a process of interpretation, rather than focusing on presentation and representation. This re–shaping of space–creation through digital tools should be presented as an educational model based on the creation of an informed architecture that invites ways of moving through not just bodily gestures of the humans themselves but relational architectural interventions.

SUBTLE PRESENCE: DESIGN AND IMPLEMENTATION OF USER CENTRIC CONTENT DELIVERY USING BIOMETRIC DATA CAPTURE AND INTELLIGENT ANALYSIS

WILLIAM PENSYL

Explores the user centric delivery Media content, using biometric data capture, intelligent analysis of facial data, age, gender and other forms of data that can be directly captured in a non-invasive manner. The system has an inherent intelligence that is ambient, and ubiquitous – allowing for interpretation of a wide variety of stimuli and that can be easily collected.

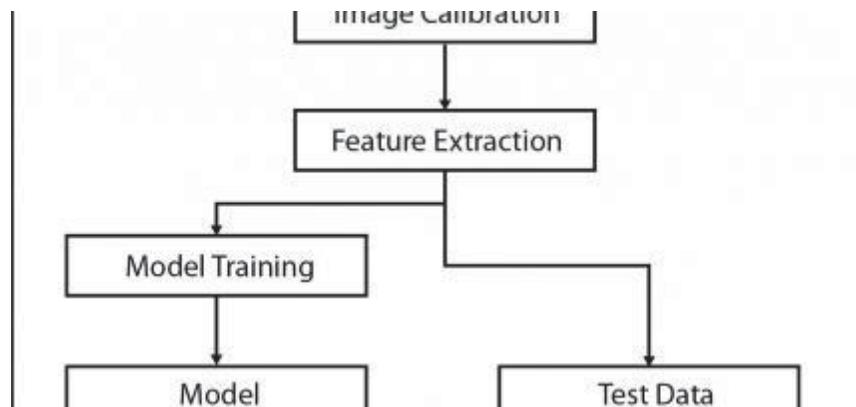

Figure 1. Processing Flow Diagram of HiPOP System

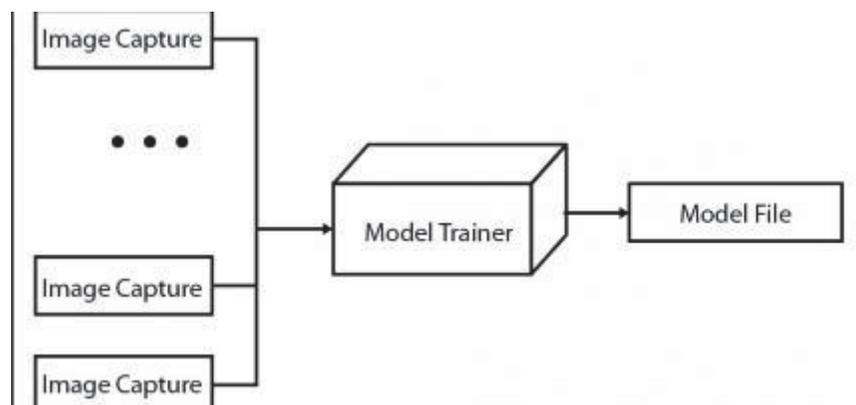

Figure 2. Data Training from Datasets

Figure 3. Subtle Presence, presented in the 2011 Sarajevo International Winter Festival.

This paper presents design and implementation of user centric content delivery using biometric data capture and intelligent analysis. We describe feasibility and successful implementation of responsive information delivery tools prefiguring facial and biometric data to cue advertising, social communication or culturally relevant user experiences. Initially designed for marketing content in public spaces, the content delivery can vary depending location and population demographics. Various forms of data, captured in a non-invasive manner, including facial images, height, body type, age, gender and aspects of mood can be used determine appropriate media delivered based on these personal attributes. To alter the type of media content presented in advertising, in retail environments, exhibition installations or public spaces, it may prove useful for media designers or systems designers to be able to assess certain personal attributes of the viewer in the space. We refer to this system as HiPOP – A High Impact Point of Purchase content delivery system.

The system uses ambient and ubiquitous intelligence to detect a face, calibrate the image and extract features to classify and determine personal attributes. After testing for gender and age group, media content is presented based on these attributes. Such a system must have an inherent intelligence and modest decision making ability that is ambient and ubiquitous – allowing for interpretation of a variety

of stimuli. The intelligence must allow meaningful responses to visual and sensor cues. There are many possible applications for the implementation this system, including, information delivery for targeted advertising, social communication in public environments. It also can be used to create socially engaging integrated media artworks within architectural and exhibition spaces. This allows viewers to engage in aesthetic experiences that are subtly responsive to their personal physical attributes and moods.

Project overview

There are a number of developments that are required for this type of information delivery. These build upon previously published biometric data capture techniques. The significance of the work lies in the development of an autonomous, intelligent system that can deliver user specific information based on the collected data of a viewer's gender, height, weight and other cues that allow for a definition of a user profile. One critical aspect to such a system is an ambient and non-invasive data capture with a naturalistic, subtle response to the user.

There has been much research on capturing user biometric information, gaze detection, posture, and these have been used to create interactive systems that allow for more natural interactions in games, interactive and environments. However, no application has been developed for point of purchase environments. In this project, we want to focus on getting useful information delivered for viewers in this specific application. Furthermore, we utilize hardware/sensor and vision systems to increase the range and accuracy of information delivery, providing better solutions for advertising, customer support, and open these platforms for the creation of interactive artistic installations.

System overview

The system processes the images captured through three modules: a "Detection Model," a "Data Training Model," and a "Demo Showing Model." The Detection Model algorithm detects a face, calibrates the image and extracts features using OpenCV, Haar-like application and LibSVM to classify and determine gender. [11], [8] An AdaBoost learning algorithm boosts classification performance. [6], [7] [8] The Data Training Model uses a cascading classification method and a LibSVM to train analysis of data and generate a final data model file. [8] The Demo Showing Model manages windows for the system and audience delivery content. The detection result is shown in face detection window and scene view window. The content images or steaming video is shown in a second display monitor.

The Detection model uses sensing and vision technology that captures a video stream, an algorithm that analyzes and identifies if a face is present, then compares the detected face to a library of defined face images organized by gender and age. This allows for the determination of characteristics including gender and age within a set of age groups. The method of detection and classification uses OpenCV Haar-like Features to find a face rectangular within the space where video camera is pointed. [1] A LibSVM is used to classify and determine the final result in gender and age bands. The results of the content delivery selected are targeted to groups that are more easily defined. [8] Gender is easier to detect than age. The fine distinction between age within the small child group, or with the adult groups is more difficult to accurately determine.

The HiPOP System is detailed in the processing flow diagram in Figure 1. The image is captured by any consumer grade webcam and passed to the face detection and image calibration module. The features are extracted via a very fast feature evaluation using Haar-like functions and AdaBoost [5] to increase to focus in a small set of critical features.

The Data Training Model is necessary to ensure the software algorithms can compare the data set of images with the library and the images captured can be calibrated to increase accuracy in the final result.

Using the LibSVM data file the system is trained to analyze the data, to classify the faces according to a set of grouped ages and genders, and to generate a final data model file. Different data models can be created using different data sets. The Demo Showing Model shows the data detection results and sends the data to playback system, either a QuickTime or Windows Media Player.

This implementation relies on published work on Haar-like Features [10]. Haar-like features are digital image features used in object recognition. They owe their name to their similarity to Haar wavelets. Viola and Jones implemented very high frame rate object detection with only the information in a single grey scale image, using rectangular Haar-like features. A simple rectangular Haar-like feature can be defined as the difference of the sum of pixels of areas inside the rectangle, which can be at any position and scale within the original image. This modified feature set is called two-rectangle feature. Viola and Jones [1] also defined three-rectangle features and four-rectangle features in the object detection framework. The values indicate certain characteristics of a particular area of the image. Each feature type can indicate the existence (or absence) of certain characteristics in the image, such as edges or changes in texture. For example, a two-rectangle feature can indicate where the border lies between a dark region and a light region.

The Viola-Jones object detection framework has three steps to extract features and classification. Rectangular Features are enclosed within a detection rectangle. The area rectangle is divided horizontally and vertically. The value of the divided rectangles is determined and the differences in features are found. Viola and Jones refer to the method employed as the "Integral Image." This first step is used to determine the rectangular features in an intermediate representation. The Integral image allows the number of iterations in processing the image to be limited, thus increasing the speed of the feature extraction. The second step uses a variant of the AdaBoost [5] to select a small set of features and train the classifier. First, collect a group of pictures, some with human faces and some without. For each image, give the image a weight ($1/m$ [human face], $1/l$ [non-human face]). And then extract "T" features from a lot of images. The processes for extraction, repeated T times are: first, standardize the weight, the sum is 1; second, pick up the feature that has smallest error; third, record the parameter where the error is smallest; and finally, refresh the image weights. After the above processes, we can decide if this image contains a face. The third step uses a set of Cascade Classifier Functions to compare iteratively against a library of images that are previously classified as faces, and within a gender or age group. Through testing and comparison of the captured face, the result is determined, within a margin of error. A larger library for comparison increases the accuracy of the result. There is a trade off in the speed of processing due the comparison of larger datasets. For purposes of this implementation, the determination needs to be very fast. To maintain a fast response, we work with a limited set of images in the library. The first step determines the results in male or female gender. Following, the face images are classified via the cascade classifier function to determine age grouping. In our implementation, the age groups are limited to child, teen, young adult, adult and seniors. The system implementation also includes the detection of a smile, adding the potential for determination of a certain amount of mood within the face of the individual viewed.

To increase the accuracy of the result, determining the age and gender, the data training models Support Vector Machines (SVMs) supervise the learning methods used for classification and regression. SVMs are classifiers that extract the results belonging to one of two categories. The SVM training algorithm builds a model that predicts whether a new example will fall in to one or the other category. The use of the SVM increases the accuracy of the resulting detection.

Implementation

The HiPOP system was designed for environments where narrow cast media is delivered in an environment; such as a retail outlet point of purchase display is maintained. Other locations where a system such as this can be employed are in any location where marketing or advertising content is presented in a public space to one person or to small groups of people. It is common that we see narrow cast information displays in point of purchase locations, elevators, entry foyers, and even in mass transit trains and subway cars. For such content delivery to have a maximum impact the content can be targeted to the person that is looking at the monitor. In these circumstances, the system can play content that is of interest to the person there. This targeting of content may increase apprehension and response by the viewer. In most cases of content delivery in these types of displays, the content is simply streamed without consideration for who may be viewing it. The content may be completely off target. For example, in a point of purchase display, the customer could be an older female. Yet the content of the media may be for a product that is commonly used only by young males. Extreme examples of this kind of disconnect occurs when the product marketed is related to a life style or behavior that may be considered inappropriate by the viewer. This could lead to a negative experience, and decreasing participation by the consumer. If the content can be targeted to the individual, then interest and participation can be maximized.

One unique feature of the HiPOP system is that the viewer is never aware that the media content is focused to them. The system simply displays the content in a seamless manner, without any indication that a detection of personal attributes is made. The system uses a web cam mounted near a display screen. The camera captures the faces in the space and detects personal attributes. Using the techniques described above, the system determines and classifies the person and then displays the targeted content. There is a limit to the accuracy of the detection. In ideal circumstances, gender detection is 80 to 85% accurate. However, since the system is designed to display the results without the knowledge of the viewer, the viewer does not experience any negative responses. They are unaware that the content displayed is the result of an inaccurate detection of personal attributes.

Another use of the system is in subtle, conceptual and artistic interactive media installations in public spaces. This is useful for interactive or streaming media content in exhibition to be displayed and altered based on the viewer's personal attributes. In Figure 3, the installation depicted alters a still life painting and changes it over time. The result of face detection alters the image according to the viewer age and gender.

In upcoming installations, importance is placed on the detection of mood. As the system software can easily detect facial expressions, the altering the content to match the mood of the viewer can easily be attempted. Current work explores how images can be shifted due to the mood displayed in the viewer in exhibition spaces. Detecting reaction to content and altering the content stream in ways that increase satisfaction is possible. Alternatively, we will explore how mood of the viewer may be affected by the images. There may be ways that various images types can be used to evoke mood shifts within the viewer. In the current installation we are detecting the smile in the viewer's faces. We can track the length of time the viewer is smiling, or other limited facial expressions. The longer one smiles, or alters their body posture; the vibrancy and saturation levels of an image can be adjusted. Other type of images can be streamed based on the visual cues collected. This new work requires "training" of the model to classify the images detected according to the set of groups defined. The library of images is stored in a database with key identifiers associated with mood: smiling, eyebrow position, eye wideness, body poster, and slope of shoulders, head tilt, or other detectable and identifiable cues.

Conclusion

Such systems can provide valuable mechanisms for delivery of media content in public places. One goal in advertising and marketing is increasing interest and engagement of the viewer. By targeting the content more closely to the person based on their own specific attributes, engagement in the content can be maximized. For artistic or conceptual installations, specific goals can be achieved through interaction that is responsive, yet unobtrusive. In the system we have implemented, there is no data or personal information is actually stored by the system. The system simply detects a face or personal cues and defines a classification of the person based on age and gender, and plays a piece of media content. This system creates a subtle responsive interaction that is unobtrusive, yet provides valuable media content that has the potential to increase viewer's engagement in meaning ways.

ART ↔ SCIENCE RELATIONALITIES

Olivier Perriquet & Bill Seaman

As science moves away from single disciplines into research that combines multiple scientific fields, we seek to discuss the possibilities of a multi-perspective approach reminiscent of Stenger's *ecology of practices* where science and the arts provide differing perspectives that can be brought into dynamic relationality.

Research and practice that explore relationships between art and science have been around for a very long time. As a subgenre of the artworld, these works and related questions are currently showing a renewal of interest. Are we simply experiencing a transient period when the frontiers between disciplines become more porous and allow for a better mutual comprehension or are we experiencing a real game-changing scenario similar to one of these paradigm shifts described by the epistemologist Thomas Kuhn?

Although initially suggesting the presentation of a taxonomy of the different relations between the Art(s) and Science(s), we have realized in our discussions that such an undertaking would call for a vast study, much broader than what we can actually address here. Nevertheless we will try to articulate a series of operative relations and explore their qualities— this is what we have termed *relationalities*. We have immediately found that each of us represent a quite different understanding of these relationalities and works of art that arise as examples of this juncture. Thus this paper will be an embodiment and synthesis of a dynamic dialogical process, sometimes synthesizing and sometimes pointing to difference. In general both of us see a difference between the practice of Science and Art. If we here adopt a position that does not take for granted that art and science are simply *two different names for the same practice, approach or activity* as sometimes claimed by the proponents of Art-Science bridging, we also believe that these domains of inquiry, seen quite separately by default, can sometimes be brought together when a conviction is established that the disparate pieces can be merged in the service of a new practice.

There has been a certain dose of play in our approach. We both believe this component is common to both art and science. Aspects of creativity are also central to both but are manifested in very different ways in general as part of their practices e.g. in science creativity might become manifest in how one approaches or frames a research problem. This work should be considered a stepping stone toward a more systematic undertaking. We have ended-up here with an initial collection of relationalities between Art and Science that one might call variations on a theme. We seek to let these entries talk and negotiate between each other, exemplifying a dialog between shots from different angles or perspectives. Drawing on Stengers' *ecology of practices*, [1] one might see here an ecology of co-existing relationalities. We typographically coined Art ↔ Science to encompass a wide range of possible relations.

Art (=∃∩≠≤≅) Science?

Having in mind a target rubric Art ↔ Science, we posit a series of overarching concerns explored under this label. A seminal book outlying one period of works is the late Stephen Wilson's Information Arts and

related website. [2] Here Wilson provides a unique set of categories that comfortably intersect with ours below:

- the development of new forms of artificial intelligence and computational practices;
- the exploration of robotics;
- the creation of intelligent environments;
- the exploration of consciousness studies;
- the study of science as it relates to understandings of the body;
- the development of new forms of interface and sensing modalities;
- the creation of new experience focusing on phenomenology, interactivity and intra-activity;
- the exploration of new materials born of scientific inquiry;
- the abstraction of particular material practices in the service of art and architectural production — e.g. biological processes, physics, and nanotechnological processes;
- the exploration of new technologies for artistic purposes — e.g. locative media, virtual reality, augmented reality, etc.;
- the use of game strategies;
- language games / mathematical games and instantiations of knowledge/concepts through play;
- the employment of media archeology / variantology and its relations as art content;
- the mining of the history and philosophy of science as subject matter;
- the exploration of databases and/or data mining;
- the employment of visualization strategies and/or the abstractions thereof;
- the use of telematic and locative potentials;
- the interest in emergence, generative strategies and dynamic/non-fixed works of art;
- works of social and cultural critical reflection focusing on scientific issues;
- political reflection critiquing scientific research;
- creativity and innovation arising out of scientific inquiry.

Each of these categories can easily be populated with a group of examples. A question that naturally emerges is whether we encompass more or less any form of Art in general, in terms of Art \leftrightarrow Science practice or not. Our short answer is no: when art is informed by science by using its materials, technologies and paradigms it expands the possibilities of creation (e.g. using new materials created by physicists or scientific concepts) and simultaneously becomes tinged with what we might call a scientific *color*.

Our question actually bifurcates: (1) can a given work be of art and of science at the same time - Seaman believes yes, where Perriquet is much more circumspect; (2) can 'any' work be described as an Art \leftrightarrow Science work - we would both say no. The physicist and philosopher Lévy-Leblond raised an interesting negative voice and argued in a recent essay [3] that the artistic approach and the scientific approach are different in nature and do not consist of a single genre, that this separation is constitutive of each field and condition of its reception. This has also been a debate between us. While Roger Malina, one of the most outspoken contemporary proponents of Art \leftrightarrow Science bridgings, published a recent rebuttal to Lévy-Leblond's text, [4] Jacques Mandelbrojt, co-editor of the Leonardo Journal, also remarked that it offers "*a point of view different from that which usually prevails in Leonardo, and it can make [the readers] find their own path by comparing those two points of view.*" [5]

We agree with the idea that neither art is a part of science in general, nor science a subset of art, nor science and art are two names for the same activity. But we adopt a softer position, considering that some works may be of art and science at the same time. Seaman defends the idea that, properly contextualized, "*science = proto-conceptual art*" while Perriquet would perceive a mix of genres only in specific

works (but appreciates the hidden and subtle recursivity of Seaman's artistic equation). Seaman's collaborative book with the scientist Otto Rössler, *Neosentience | The Benevolence Engine*, [6] exemplifies this equation. Seaman calls this approach Recombinant Informatics, exploring a multi-perspective approach to knowledge production. A methodology to investigate the meanings of a mixed-genre work, can be taken up by observing it through artistic glasses as well as through scientific lens (additionally works can also be addressed from other disciplines e.g. the humanities). Wearing these alternating lens provides differing perspectives, resulting in different discourses on the same object or experience.

Works of art-science collaboration may end up in differing output arenas, where the scientist might publish about what they take away from an art-science collaboration in a journal or book chapter, the artist may manifest the result in an exhibition, installation or other form. Concretely, daily scientific productions are mainly publications, addressed to colleagues, and subject to peer-review, whereas artworks are intended for an audience that is not usually made up of artists alone. Framing a work as Art and Science at the same time implies some specificities, such as targeting a public (this is not the usual goal of scientific research) or questioning tacit scientific standard that we may roughly gather under the banner of objectivity. An artist has a right for raising a much more subjective voice: by claiming "*this is an artwork*", his work becomes indeed an artwork, as per trans-substantiation. There is no similar option in science. Non-orthodox researchers such as Wilhelm Reich or Emile Benveniste, among many others, were excluded from the scientific community at their time for non-conformity with the constitutive rules of science. This inclusion / exclusion framework is a bit caricatural: Art also sets tacit rules for the cooptation of its members, and objectivity in science is a complex and widely discussed concept, having a History and assumably different meanings in hard and soft sciences. This example, however, outlines just one variable in the tricky *equation* the community possibly emerging at the intersection would have to solve.

Science ⇄ Art ⇄ Science ⇄ Art ⇄ Science ⇄ Art

Art seems non-linear in its historical progressions. Scientific knowledge, in comparison, is cumulative, there is a notion of progress that is not so pregnant in art. This point could be discussed, though: one cannot address the question of randomness in art after the drippings of Pollock or the question of the unconscious after the works of the surrealists as if nothing was already done. Whether we call it progress or not is a subtle debate, but at least an artist knows that he/she does not start from scratch. History plays an important role in art, in appearance maybe more so than in science. A physicist, a mathematician or a biologist may be trained only with recent formulations of physics, math or biology and have only a reduced knowledge of the History of his discipline (we imagine that the revolutionary figures, in contrast, always know the History of their science). Art and Science practices must contend with this perhaps subtle difference between art and science in terms of progression.

Certainly science has a different epistemological background related to its concrete functioning – the study of knowledge and its methodologies for justifying its belief. We can explore this from multiple perspectives in the writings of Bachelard, Latour, Kuhn, Feyerabend, Popper and Stengers.[7] We here orient our focus on the work of Kuhn, whom we find illuminating for our concern (a critical discussion on the relative positions of the former epistemologists is beyond the scope of this paper). When arguing that science does not explicitly articulate its rules but functions instead according to *paradigms*, Kuhn offers a conceptual apparatus for ongoing change. We might compare this to the notion of the avant-garde in the arts. Normal science, says Kuhn "*does and must continually strive to bring theory and fact*

into closer agreement, and that activity can easily be seen as testing or as a search for confirmation or falsification." [8]

Where science must uphold strong standards of truth - here labeled falsifiability (Popper's concept) - art is more open in its strategies and relation to the truth. The famous quote "*art is the lie that tells the truth*" from Picasso, illuminates the complexity and perhaps polarity to that of science in terms of the relations that art explores in the domain of practice. Art has this potential to extend the traditional boundaries of Truth and we provide the hypothesis that there is a similar expansion of logical truth which is at stake when in mathematics one thinks of a visual demonstration of elementary geometry or a computational proof in number theory. This conception and the subsequent debate or controversy it stimulates could be compared to the contemporary understanding of what an artwork is, after Duchamp. Witness here Duchamp's ideas surrounding a *playful physics*. [9] While a painting includes the viewer's gaze in its definition, a contemporary proof (as many contemporary artworks) may include the viewer's cognitive faculties within its boundaries. Interestingly, Hans Diebner who has also worked and written exploring art and science relationality, has defined a new approach to scientific inquiry he calls Performative Science. [10] His work explores in part complex systems and suggests that certain results are time-based and not repeatable. He is deeply interested in a proto-hermeneutics. This is an example where the performative notion relevant to the arts functions in the service of scientific inquiry.

(Art \rightarrow Science) & (Art \leftarrow Science)

Scientific knowledge is traditionally organized hierarchically: is it inherent to its nature? For example, in mathematics, it is hard to start teaching to a student what the cohomology of finite groups is, if he/she does not even know what a group is in the mathematical sense. It may simply be difficult to understand the need for the invention of such a structure without a prior manipulation of different kinds of simple operations in various contexts (multiplication on numbers, rotations in geometry, etc.).

Bourbaki, a collective pseudonym standing for a group of mathematicians of the 20th century, wrote a series of books presenting an exposition of modern advanced mathematics. With the goal of founding all of mathematics on set theory, the group strove for rigor and generality. Each volume starts with an introductory explanation: "*The method of exposition we have chosen is axiomatic, and normally proceeds from the general to the particular.*" [11] and also, with a possible coefficient of irony (ranging from zero to one, up to the reader's beliefs), "*In principle, it requires no particular knowledge of mathematics on the readers' part, but only a certain familiarity with mathematical reasoning and a certain capacity for abstract thought.*" There exists a propensity to organize scientific knowledge hierarchically. Yet, it is interesting to think about how Science might gain from Art at this level: finding a different way to organize and access its knowledge, as well as a means to stimulate insight and new knowledge production through the potentials of association and juxtaposition.

In exploring the relationality of language used in the service of Art \leftrightarrow Science Relationalities, language should be understood in the broadest sense: there is an intimate relation between a given language and its potential expressiveness. The limits of language, for Wittgenstein as discussed in the *Tractatus*, [12] indicate and set the limits of thought, or the limits of a particular world circumscribed by these thoughts. Mathematicians often use words as simple as group, field, action, natural transformation, etc. to name high level abstract algebraic objects: what is at play here is the complexity of the concepts this language embodies (Deleuze and Guattari would rather speak about *functions* in science and leave *concepts* to the philosophers, *affects* and *percepts* to the artists). [13] In general, scientific language seeks

to be precise and monovalent. Language supporting the arts moves from the clarity of art historical and formal definitions to the poetic, having obscure, and polyvalent potentials. The word may also function as part of an image as both an aesthetic object and a linguistic signifier, superimposing signifying domains. In terms of Art ↔ Science collaboration, certain goals related to the construction of a bridging language may be undertaken. Simplifications have always existed in general-public magazines of science or in lectures intended for a wide audience, but the close interaction with scientists offered to artists in residency in scientific laboratories may lead them to function at times as bridges with a wider or different non-scientific audience; these lucky artists may in return inform their own practice by methodologies imported from science while at the same time illuminate science with an unusual light spot.

Art % Science

Embodying both approaches, Leonardo Da Vinci has become an icon in Art ↔ Science rhetorics because he has been known as a major character for his unequalled contribution both to the sciences and the arts of the Renaissance. A focus on Leonardo's work confirms that History is an important factor in the study of Art ↔ Science bridgings. Leonardo lived a long time before the modern and contemporary conception of science, now concerned with falsifiability and reproducibility of experiments, ie. at a time when the operational concept of objectivity was not yet normalized by an advanced meta-discourse on scientific practice, combined with the intensification of scientific and technological productions. It is interesting to think how an artist like Leonardo functions today in relation to our contemporary conception of the image: *"Another unusual feature in Leonardo's writings is the relationship between word and picture in the notebooks. [...] Leonardo gave absolute precedence to the illustration over the written word in his teaching method. Hence, in his notebooks, the drawing does not illustrate the text; rather, the text serves to explain the picture. In formulating his own principle of graphic representations — which he called *dimostrazione* (demonstrations) — Leonardo's work was a precursor of modern scientific illustration."* [14]

We understand and believe that Leonardo's work, rather than being a mere discovery of illustration in science, may have been precursory to scientific visualization as we conceive today: the art of gaining insight into a problem by visual means. Taking data visualization as an example, we realize this form of practice can fall within the Art ↔ Science spectrum of relationalities where one may either work on an abstraction of data visualization with the intention of creating a work of art or may draw on art and design concepts to make a more effective display of scientific informations. Visualization not only relaxes the mind from getting lost in too much abstraction, but helps shape a given problem along particular lines of thought, that, when cognitively dismantled into understandable units by the viewer's eyes and brain, provides what Leonardo called *dimostrazione*. It's worth remarking that science might sometimes still call this methodology a demonstration, keeping the dual and ambiguous meaning of *concrete representation* and *logical proof*.

The intrusion of such methodologies from outside of science, reminds (and provides an example to) the strong encounter of Art and Science claimed by Malina, who states: *"[...] the history of science does not follow a logical path of increasing completeness. Instead the history of science is punctuated by the introduction into the scientific methods of ideas and methods from outside of science. The scientific method itself evolves. Facts, theories and methods which would not have been considered scientific a hundred years ago, are now mainstream science. ... I argue that one of the reasons for encouraging the interac-*

tion of art and science is to facilitate the migration of ideas and methods from outside of science into science. I call this the 'strong case' for art-science interaction." [15] One can imagine a dual strong interaction where the intrusion of methodologies from outside of art also transforms artistic practices.

Art ☆ Science

Having reached the conclusion we find ourselves just at the beginning of a vast study. We certainly hope that we have in part reflected the plurality of practices involved here and started to articulate a multi-perspective approach which allows for a circle that encompasses many foci and multiple points of view. At some point this appears to be a paradoxical undertaking, and probably we are pulling out the rug beneath the very footing that we are currently bootstrapping, by embracing this multiplicity of perspectives. But each person involved in Art ↔ Science practices positions *themselves* differently and our remote goal is to embrace these inner and outer diversities.

YOU HOLD THE CAMERA NOW: AN ACTION RESEARCH CASE STUDY OF PRE-KINDERGARTEN TRANSMEDIA NARRATIVE DESIGN

Gabriel Peters-Lazaro

This paper presents findings from a pilot research project called the Junior Audio-Video Club. Through an account of our experimental pedagogical approaches this paper aims to identify key insights and challenges to the pursuit of early childhood media arts education, and to explore the relationship between art practice and research.

Student participants in the Junior AV Club collaborate on a video editing project. Copyright University of Southern California.

“It’s like somebody telling a story, except it’s on a screen.” This observation about the relationship between movies and storytelling was made by a four-year-old student at the outset of a project called the Junior Audio-Video (AV) Club undertaken by a group of media arts scholars and practitioners at the Institute for Multimedia Literacy in the fall of 2009. A research and teaching unit within the University of Southern California’s School of Cinematic Arts, the Institute for Multimedia Literacy, or IML, is dedicated to promoting media literacy within networked cultures at all levels of education. The Junior AV Club, an ongoing action research project investigating how digital media tools facilitate learning for early

primary students within a pedagogical framework based on computational literacies, represents the IML's first foray into pre-K and early primary education. As an IML staff person and PhD student in Media Arts and Practice (iMAP) at USC, my role within the Junior AV Club has been that of curriculum designer, lead instructor and researcher. I am in the process of expanding the research goals of the project and making it the basis of my dissertation work.

This paper is an "in-progress" introduction to the project; it is not a comprehensive report of findings and conclusions as we have not yet reached that phase of the process. At this stage we are focused on a practical approach to developing classroom interventions and have yet to assess the outcomes of those interventions. I share our work at this phase as an example of how the processes and skills of an arts practice background may contribute to research endeavors.

The Junior AV Club was inspired by a 2009 evaluation of the Ready To Learn Initiative that found positive effects on the basic literacy skills of preschoolers when exposed to media rich educational materials. The IML partnered with a neighboring preschool and conducted a one-day workshop in digital storytelling and recombinative narrative with a group of 18 four- and five-year old students. The success of that pilot workshop led us to develop and implement a 10-week project in the spring of 2010.

Students came to the IML each week in groups of 10 for 90-minute sessions on transmedia digital storytelling. An early lesson dealt with still image production, analysis and categorization. Students learned to take photos using digital still cameras. Once students had their photos loaded onto IML computers, they each chose three pictures to arrange on a single page with a sentence of text (dictated to an adult) explaining their choices. Compositions included groupings based on color, personal preference, and the idea that the same thing can look very different depending on how close or far away the camera was when the picture was taken.

This lesson illustrates our pedagogical approach to the Junior AV Club in a number of ways. For one, it created an opportunity for practical media production skills in a context that promoted critical media literacy. Additionally, the language of visual literacy that we introduced to describe and categorize images tied in to the traditional literacy skills students were learning in their regular classroom, supporting concepts of patterning, seriation and classification. The activity also illustrated a common student relationship with technology: students expressed excitement about using digital cameras and shared anecdotes about their prior experiences using or observing such technologies in familial contexts.

Since completing that first 10-week session and reflecting upon our experience, we have gone on to conduct two more iterations of the Junior AV Club in the summers of 2010 and 2011. We refined our lessons and activities, expanded our approach to include computational literacies and game design alongside visual literacies and storytelling, and have focused as much on how we teach as what we teach. We strive to create a learning-rich environment facilitating challenge-based peer-driven inquiry where technology is a naturalized part of the landscape.

In the latest iteration of the Junior AV Club we examined how iPad tablet devices function as learning tools and encourage computational thinking. We found that iPads were useful for information recording and sharing between students just learning to read and write, and that well designed iPad apps could be effective models of abstract concepts such as computer programming. However, we found that many iPad apps encouraged single-user experience at the expense of group cohesion and we would like to see development of more apps that can support the creative learning activities of a defined group of local users, creating an effective virtual extension of classroom spaces and activities.

Technology in the classroom is not an answer in itself to the changing needs of educational systems. However, as the affordances of new technologies support novel structures of social interaction, skill sharing and network building, there are opportunities to re-imagine what teaching and learning look like. There is much positive work being done around these ideas, and I am particularly excited by the research, writing and pedagogical examples of Mizuko Ito, Douglas Thomas, John Seely Brown and Katie Salen, along with the field building efforts of the MacArthur foundation in the area of digital media and

learning. Within this investigative space I see a place for the research contributions of arts practitioners and educators, and offer some context about my own arrival within this community as an illustration.

When I first began making documentary video art, I learned by instinct and self-guided research. I later expanded my self-developed processes and skills with a formal arts practice education, earning an MFA in film directing and production from UCLA. But my richest learning experiences were those that I pursued on my own. As an arts educator, I strive to create circumstances in which students can discover and strengthen their own vision and creative process rather than presenting them with a predetermined set of rules.

I came to the research process of the Junior AV Club much as I did to the art practice process, working from a desire to do, to explore and to learn. This openness to experimentation carried over into my interactions with the students through a willingness to adapt our approach to their feedback and needs rather than try to mold them to a preconceived plan and concept of how an activity was supposed to go. This flexibility and openness to the reality unfolding in front of and around me has always been key to my successful creative experiences. We carried out our research like art practice, and it turned out that one of our main research goals was to learn how best to structure learning that way too. Moving forward with the project along the iterative feedback loops of an action research system, I hope to enlarge the Junior AV Club's community of collaborators, to incorporate more expertise and methodology from education research, and to develop functional tools and publications that can benefit communities beyond the laboratory space of the IML.

PURSUING THE UNKNOWNABLE THROUGH TRANSFORMATIVE SPACES

MAJA PETRIĆ

My work is about changing the perception of space in function of art. Therefore, the subjects of my work are perception, space and, art. To change perception, I study sensation, experience, and phenomenology. To create spatial situations, I practice designing spaces, fabricating structures, manipulating materials, and integrating lighting and audiovisual systems. The core of my artistic research is the pursuit of the unknowable— the sublime.

Historical Background of the Sublime

The core of my artistic research is the sublime. To illuminate my artistic engagement, I will elaborate on the history and theory of the sublime. While the term has had a long life full of passionate relationships with philosophers and artists who have attempted to reveal its essence, that has not led to a unified definition of its meaning. "What is the sublime? It does not appear to have been defined. Is it a figure of speech? Does it spring from figures, or at least from some figures of speech? Does the sublime enter into all kinds of writings, or are grand subjects only fit for it?" (La Bruyère).

The first mention of the sublime is found in writings of Longinus, the Greek rhetorician and philosopher of the Neoplatonic school. In "On the Sublime", which is thought to have been written between the third and first century AD, Longinus discussed the sublime as something great, elevated, or lofty that manifests itself in what is beautiful. In the seventeenth century, British philosopher John Dennis expanded Longinus' definition by introducing horror as an additional aesthetic quality that can create the sublime. After embarking on a journey across the Alps to Italy John Dennis described the term as "delight that is consistent with reason," and "pleasure to the eye as music is to the ear," but also "mingled with Horrors, and sometimes almost with despair" (Pack and Dennis).

Several years later, British philosopher Edmund Burke proclaimed that horror is not only another potential source of the sublime, but the most potent one. In 1756 he published "A Philosophical Enquiry into the Origin of Our Ideas of the Sublime and Beautiful". Burke wrote: "Whatever is fitted in any sort to excite the ideas of pain, and danger, that is to say, whatever is in any sort terrible, or is conversant about

terrible objects, or operates in a manner analogous to terror, is a source of the sublime; that is, it is productive of the strongest emotion which the mind is capable of feeling... Terror is in all cases whatsoever, either more openly or latently, the ruling principle of the sublime" (Burke).

Prominent German philosopher Immanuel Kant followed Burke's enquiry in 1790 by writing a theory of aesthetics that was published in *Critique of Judgment*. In the chapter "Analytic of the Beautiful", Kant disassociated the beautiful from the sublime. While the beautiful is concrete, he explained "it is connected with the form of the object." And, the sublime is intangible, "it is to be found in a formless object" (Kant). Beauty can be reasoned, but to experience the sublime it is necessary to go beyond reason and employ sensibility and imagination. The ability to transcend reason by fusing it with the nature of senses is the vehicle of the sublime that Kant called a "supersensible substrate." He associated this ability with individuals who pose both superior mindfulness and superior sensibility of the body.

For Kant sublime is not an object—it is a state of mind we must enter that enables us the experience. We experience the sublime when our imagination fails to conceive the greatness of events solely by means of reason but compensates for this failure with pleasurable sensations that can be manifested through synthesis of senses with virtue of reason. Sublime as an experience is independent of any conceptualization or perception by the human mind. It is a thing-in-itself that Kant called the noumenon, postulated by practical reason but existing in a condition which is in principle unknowable.

Kant's theory prompted even more vivid discussion about the nature of the sublime, which created new possible frameworks for the subject. None of these were accepted as a unique model of the concept through which they demonstrated the impossibility to frame the sublime. This only confirmed Kant's definition of it as the unknowable. So essentially if what we experience is unknowable, the question is how do we experience the unknowable. All the previous theories depicted it as a dichotomic experience that is both wonderful and terrible.

Getting to Know Unknowable as Both Wonderful and Terrible

Multiplicity of that experience, the dichotomy between bliss and horror, beauty and ugliness, pleasure and pain, comfort and torment, divine and hell as distinct instances of the single sublime that can be experienced through integration of cognitive and sensory ability is the most persistent in religious mythology. Religions that promote transcendence through light and darkness have illustrated the sublime as the crossing point towards the numinous, the presence of a divinity.

According to the German theologian Rudolf Otto, crossing the bridge of the sublime is encouraged both by *mysterium tremendum et fascinans* ("fearful and fascinating mystery"), the pains and terrors overwhelming those who have arrived affront of God, and "nostalgia for paradise" (Otto), aching desire to reach the abode of perfection. In Christianity, the God is light, but the God is also darkness. "And the light shineth in darkness; and the darkness comprehended it not" (John 1:5).

Contradictions of the sublime have been depicted in art since the beginning of art history. These works differ in a degree of simulating and emulating the experience of the sublime. For example, Dante's "The Divine Comedy" uses the narrative to create a representation of soul's journey through Inferno, Purgatorio, and Paradiso. It simulates, projects the idea, of experiencing Dante the Pilgrim's journey. To a de-

gree, it also emulates the actual feeling of being on a path from hell to heaven. It can make a reader experience the poem as if they were the first person of the poem. But it is predominantly a representational narrative of the sublime simulated in an afterlife of any everyday sinner.

Myths of heaven and hell have functioned to interpret the world and its counterparts, but also to entice the audience into experiencing its parts. The enticement into the fearful and blissful mystery is where the art comes in. Postmodern French philosopher and literary theorist Jean-François Lyotard recognized avant-garde art as a novel opportunity for accessing the sublime. He argued that the nature of avant-garde modern art has the unique potential to manipulate the balance of senses, reason, and emotion in a manner that results in a sensation of pleasurable pain. My further investigation is in practice of art that carefully entices senses, reason, and emotion in a way that results in an experience of the unknowable.

Works of art that predominantly emulate the experience of the sublime are aligned with twentieth century French philosophy in the domain of post-structuralism that views the structural relationship between the signifier and signified as inseparable but not united. In the artistic discourse the structure creates nonlinear meaning, and the audience replaces the author as the primary subject of inquiry. These ideas extend to the philosophical concept of phenomenology that focus on the "first person" viewpoint, which can then be examined as phenomena that not only appears to "my" consciousness, but to all consciousnesses. According to German philosopher Edmund Husserl, "the synthesized experience is what constitutes total human knowledge."

One of the first artists exploring the phenomenological experience of the sublime was English Romantic landscape painter Joseph Mallord William Turner. His most notable painting, "The Snowstorm: Steamboat Off a Harbour's Mouth Making Signals in Shallow Water" (1842) portrays a ship in distress off the English coast with a high degree abstraction, asymmetrical composition, and monochromatic palette. The painting documents the ship caught in the storm by depicting the experience of witnessing the ship in the storm, instead of merely realistically reproducing the look of the scene. The painting not only informs us about what happened to the steamboat at the Harbour's Mouth during the snowstorm, but it also physically immerses us in the event. It is a beautiful and terrifying visceral experience, creating an example of the sublime in painting.

Several centuries after Turner, vision as the highest in the historical hierarchy of senses was slowly making space for other senses—and a fuller sensory experience. The industrial revelations of the twentieth century made an impact on art and how it is experienced. Artists including Anish Kapoor, Mark Rothko, Bill Viola, and James Turrell marked the twentieth century as an age of expanding our sensing apparatus to experience the sublime. Through their abstract but integrated use of materials, space, color, light, and image, they excite our senses and intrigue our minds to the point of reaching the essence of the unknowable.

The technological age is allowing for more multisensory engagement. My interest is in exploiting those technological advancements that can fuse perception of senses and add to the phenomenological experience of my artistic intention of presenting the presence of the unrepresentable. "My perception is [therefore] not a sum of visual, tactile, and audible givens: I perceive in a total way with my whole being: I grasp a unique structure of the thing, a unique way of being, which speaks to all my senses at once (Merleau-Ponty).

To be fully present in the world, one needs to use all available senses and intimately interact with the environment using their eyes, nose, ears, and skin. Only through receptiveness of the entire sensing mechanism is it possible to have a profound sensation of the place that can then be emotionally and cognitively processed into a meaningful experience. In the context of art, maximized engagement of the senses can direct memory and imagination into a place where the sublime can be experienced.

Pursuing Both Wonderful And Terrible Through Transformative Spaces

I was born and raised in Croatia during the violent fragmentation of Yugoslavia. It is then that I became preoccupied with using art to transform the traumatized sense of the surroundings. My work is about changing the perception of space in function of art. Therefore, the subjects of my work are perception, space and, art. To change perception, I study sensation, experience, and phenomenology. To create spatial situations, I practice designing spaces, fabricating structures, manipulating materials, and integrating lighting and audiovisual systems. The core of my artistic research is the pursuit of the unknowable— the sublime.

My interest is not to define the sublime. Critical history has proven that the sublime cannot be precisely put into words, just as the meaning of life is inherently unknowable. Nineteenth century Danish philosopher, theologian, and psychologist Søren Kierkegaard argued that logic of the objective knowledge and rational belief is unimportant to existence. If the deity could rationally be argued, existence of the supernatural being would be unimportant to humans. It is because God cannot rationally be proven that his existence is essential.

The sublime, as an agnostic term, cannot be made into an object of knowledge through language, reasoning, logic, and concepts. But it can be experienced. Since it is unknowable but can be experienced, it is profoundly valuable to experience it. My interest is in the experience of the inherently unknowable sublime. This experience has been described both as awe and terror. My interest is in the division and range between two mutually exclusive, opposed, or contradictory sensations as distinct instances of the single sublime. Therein lies the opportunity for the multiplicity of an experience, which can than also be created in art.

My approach combines traditional and progressive principles of spatial design fabrication, lighting design, audiovisual systems, and multisensory devices. By utilizing technological advancement in traditional mediums and untraditional integration of those mediums I aim to discover, interpret, and develop novel body of knowledge for enhancing the multisensory spatial experience that provides access to the sublime in the purpose of art.

One of the first projects that clearly illustrate my fascination with transforming the poetic experience of the space is the “outSIDEin”. It is an interactive light installation that was created in year 2004 to transform the atmosphere of the shattered pedestrian tunnel at New York City Subway’s 191st Street station of the number 1 train. There, I use artificial light to simulate a striking natural effect of light emanating from the sky, which is projected through false cracks of the ceiling in the pedestrian tunnel. Lights are programmed to imitate the color and intensity of the daylight outside of the tunnel. When the weather outside is very sunny, the light projected inside through the cracks is bright and yellow. When the weather outside is foggy, the light is blue.

The “outSIDEin” project has been an inspiration for further investigation about the live transformation of the spatial experience. In light and video installation “As It Is Cracking”, the wall in the room cracks in real time. As the wall cracks, lights and video appear through the cracks to create an experience that ranges from frightful to pleasurable. Daunting cracking of the wall in real time happens over the course of eight hours. Light and moving images appearing through the cracks simulate slow and steady change of daylight. This change is interrupted by sudden and startling appearance of lightning.

In 2009, I have collaborated with a choreographer Jennifer Salk in a dance performance “The Eyes of The Skin”. We explored the often twisted and delicate nature of tenderness, which is defined as a tendency to express warm, compassionate, or affectionate feelings. But in medicine it stands for pain or discomfort when an affected area is touched. By definition, tenderness is both a pleasure and pain as a result of susceptibility that is being defined by juxtaposition of the two opposed characteristics. I focused on the dichotomy of tenderness that ranges between pleasure and pain and as such relates to her research of the sublime and the multiplicity of the sublime experience. My ideas were combined in a form of the deteriorated wall that covers the north wall of the stage and that cracks over the course of a performance. As the wall is cracking, the light appears through the cracks and changes color and intensity in response to dancer’s behavior and dance narrative.

In the mentioned projects, the crack is an instigator of the spatial transformation that becomes both wonderful and terrible. As such it is a symbol and emulation of the sublime that can be captured only through the personal sensing mechanism. Capturing the presence of the unknowable remains to be the goal of art.

BIG BIRD IS WATCHING YOU! ART, ACTIVISM AND TECHNOLOGY IN THE PUBLIC ARENA

DENITSA PETROVA

Many contemporary artists working in the public arena have recognised the potential that the rapid development of digital media technologies presents. This paper discusses the potential of art and technology collaborations stimulated by the continuous transformation of our cities. It explores the intersection between art, activism and technology as a new art practice used as a tool for creating situations prompting cultural change.

Introduction

Today, George Orwell would have felt like a prophet if he was able to walk the streets of London and see the thousands of CCTV cameras following, and recording, pedestrians and vehicles. Perhaps he would have been inspired to write another novel if he knew how technology had progressed, allowing satellites to track down car license plate numbers and mobile phone signals to within a matter of meters of their geographical location, all from outer-space. Some people now believe that most of Orwell's predictions are now being integrated into our free society. Finger prints, retina recognition, phone taps – these are all now mechanisms that governments use to manage countries and people. Do we now live in the modern day Oceania? [1]

Perhaps Orwell was right - war really is peace; we simply need to look back to the not so distant Cold War decades to realize that fear was keeping peace on this planet. Globalization impacts our lives and is widening the income gap between the rich and poor. This is strongly reflected in public space, which is now becoming more increasingly managed and controlled. Perhaps the reason that we have so many brain-numbing reality TV shows today is because governments and media are embracing the mantra that ignorance is strength. This is strength for the powerful economic conglomerates, the financial corporations, insurance companies and banks. Could the TV Show *Big Brother* be the present-day *Newspeak*, that makes "all other modes of thought impossible?" [2] Because whilst we are watching *Big Brother*, our minds are occupied and we do not question what is really happening with the world around us or what is happening with the public space that is meant to belong to us, the public. But is this just a camera trick?

What is the role of the artist today in relation to the challenging political, social, and economical climate? The Dutch painter Piet Mondrian thought of the artist as someone whose position is humble and who is "essentially a channel." [3] Mondrian lived and worked at the end of the 19th and the beginning of the 20th century, the dawn of Modernism. He was interested in theosophy, a movement launched in the late 19th century, which was centered on the importance of the interconnectedness of the whole universe. Perhaps this fact relates to Mondrian's description of the role of the artist as a channel - a channel of ideas, a link between real and imaginary, or as someone who is able to reconcile their creative pursuits with their understandings and beliefs about life.

Precisely, this role of the artists as a channel of ideas reveals itself in the projects discussed later in this paper. However, the artist today is more than a generator of objects or channel of ideas. Many artists

today are becoming catalysts for political, social, and cultural change. This notion is strongly reflected in the concepts of various activist art practices, which are most commonly seen outside the gallery space as their creators are trying to reach a larger audience. These artists are trying to point out what is happening in the public space today; their strategies are becoming more vocal and effective and many art groups and individual artists are working anonymously in order to deliver their true message.

There are various ways in which activists interfere with our physical and social environment today. This paper presents a selection of examples which illustrate, in a witty and playful way, the tactics and methods used by artists and art collectives. This essay examines the works of contemporary artists and art collectives who use the power of technology to publicly engage political, social, and community issues.

One may rightly ask the question, “Why do we call these practices art?” It could be “community practice”, or perhaps “political action”, or none or all of the above. The majority of these works are project, rather than object, orientated. Nina Felshin describes it as an activist cultural practice with “...one foot in the art world and the other in the world of political activism and community organizing.” [4] In his book, *Art Matters*, Peter de Bolla suggests that our attention should not only be directed at the obvious aesthetic values of the artwork but at our experience of it. He also notes that “...the great value of art lies in its power to prompt us to share experiences, beliefs, and differences.” [5] Perhaps we can find the meaning, value, and significance of activist art not in the art object itself but in the idea of conveying a message, provoking thought, and creating a dialogue not only between the artists and their audience, but between the audience members themselves as well.

Who can initiate, create, or take part in activist art projects? Anyone can. Not being an artist does not mean that a member of the general public can not initiate or participate in activist activities. At the same time, artists are part of the public and they have as much right to intervene with the public space as anyone else. These projects and actions are representations of the messages that the artists are hoping to spread. The outcome of these practices is not necessarily the actual artwork, but rather a passage to the particular idea that the artist had in mind. Furthermore, these practices are inspired not by the intimate world of the artist but are focused on what is happening in our public space today.

John Henry Strikes Back

Often, activist art projects are collaborative and done anonymously. They have no specific author and, most often, are the result of teamwork between artists, architects, programmers, engineers, and activists. The individual authorship is not important, especially as the number of the members of the art collectives is never a constant. Additionally, the vast development in technology has contributed to the decreased notion of expression of the individual. As described by Marchal McLuhan, “...as new technologies come into play, people are less and less convinced of the importance of self-expression. Teamwork succeeds private effort.” [6]

Founded in 1998, the Institute of Applied Autonomy (IAA) is an art group dedicated to creating activist projects which call for social or political change. Most of the IAA members are anonymous, not simply because some of the promoted works are conducted ‘guerrilla style’, but because the authors are trying to keep public attention focused not on the artist, but on the problems that the work is dealing with. They use the name John Henry as a collective nickname which unites a group of artists, engineers, and activists under the idea of using technology to raise public awareness on social and political issues.

One of their more recent works, the *GraffitiWriter*, was developed in response to the increased government funding for military robotic development. By 2030, the Pentagon is planning to replace about 30 per cent of its armed forces with robots, or as Professor Bill Smart, one of the project leaders from Washington University, calls them “autonomous systems.” [7] Powerful robots will lead human soldiers into battle within the next decade. In response to these plans, The Institute of Applied Autonomy developed the *GraffitiWriter*. The robots can operate in parks, shopping malls, and buildings and its purpose is to disseminate subversive and politically controversial texts. With the help of an operator and a remote control, the *GraffitiWriter* sprays linear messages on the ground. In 2004, the robot was set up to take part in the Grand Challenge, a military robotics event organized by the research and development office for the U.S. Department of Defense. *GraffitiWriter*’s mission was to print Isaac Asimov’s First Law of Robotics – “A robot may not injure a human being...” – at the starting line of the event.

In a similar fashion, in 1993, the art collective RTMark conducted a controversial act of product hacking by developing a project called *Barbie Liberation*. The mission of the project was to challenge gender stereotypes in the children toys industry by performing voice surgery. The project involved swapping the voice boxes of Barbie Dolls and GI Joe toys in a number of toy stores in the United States. The toys were returned to the stores with switched voice clips and, without the knowledge of the staff, were released back on the market. Many children heard their Barbie dolls shouting “Vengeance is mine!” and GI Joe soldiers saying “Let’s plan our dream wedding!” The website of RTMark provides a manual with a step-by-step guide how to perform the voice surgery. Since then, Barbie has evolved and embarked upon many different professions such as becoming an astronaut, doctor, police officer, and even a presidential candidate.

One Nation under CCTV

In 2001, The Institute of Applied Autonomy initiated a project called *ISee*. It was created in response to the vast growth of CCTV surveillance of public spaces. The web-based application was first developed for the streets of Manhattan mapping the locations of the cameras. Via the *ISee* website, anyone can generate a route with the least number of cameras watching them and walk around the streets without the uncomfortable feeling of being filmed without permission.

Research has showed that most CCTV cameras in New York were placed in the financial district of Manhattan but not in the poorest and most unsafe areas of the city. [8] One has to wonder if the cameras are actually keeping people safe or protecting the property of the wealthiest. Another study done in the United Kingdom revealed that CCTV cameras in Glasgow’s city center did not actually have a significant impact on crime in the area. [9] Projects such as *ISee* do not question the use of video surveillance to prevent crime as a whole but rather its effectiveness. Furthermore, the authors are trying to draw attention to the fact that many of the public space cameras are actually privately owned by banks and stores, which undoubtedly makes the recordings private property.

Created in 2007, Celine Shenton’s *Bird City* also tackles similar issues. The project consists of series of bird houses for urban areas. The birdcages look like surveillance cameras but, in fact, they really offer refuge to birds. Shenton installed real video cameras inside the bird houses which were able to broadcast video of the bird’s life to the nearby homes. As an alternative to TV shows such as *Big Brother*, *The Bachelorette* and *Celebrity Detox Camp*, this work offers multiple thought provoking points regarding our dehumanized urban spaces and increasing detachment from nature.

In the same fashion, apart from trying to convey a message, the work of Tad Hirsch's *Tripwire* also offers a real solution to a specific problem. The project is designed for a specific suburban area of California near the San Jose International Airport. Hirsch's custom built sensors were mounted inside coconuts and attached to real trees in the noisiest areas of the neighborhood. When an excessive aircraft noise was detected, the sensors would trigger automated phone calls to the complaint line of the San Jose Airport on behalf of the citizens.

Another public space intervention, involving media memory, is represented in the *Image Fulgurator*. This is essentially a photo hacking project which embeds an image onto the photos of an unsuspecting photographer. The result of this photo graffiti is only visible after the original film has been developed, or after the image is viewed on the camera screen or on a computer.

The *Image Fulgurator* is, technically, a classic photo camera which uses exposed and developed film with images on it. A device inside the Fulgurator detects when a flash goes off and automatically projects the image onto the object which is being photographed. The photo intervention is particularly effective when used in public spaces that have particular political significance. The author of the project, Berlin-based artist Julius von Bismarck, sees it as a piece of art which could be a dangerous attack on the media.

Mash It Up

The rapid development of technology during the past few decades, plus the open access to information facilitated by these new technologies, has created a new public space for politically orientated dialogue – the internet. The internet is also a creative space, an enormous arena for social interaction, and at the same time, an open canvas for work and collaboration.

The term “mash-up” originates from the hip-hop music genre and represents a specific style of mixing two or more songs. In technology, the concept of combining different software is not new. Internet “mash-ups” consist of combining information and services of different websites in order to create a new project. Most commonly, internet mash-ups use a combination of online maps, such as Google maps, and mapping locating service applications.

A creative mash-up that locates informal play spaces in Sao Paulo was created by the Spanish art collective, Basurama. As part of a research project, the group developed an interactive map of urban spaces which could also be used as informal playgrounds. The images can be uploaded by any member of the public, and Wikimap reveals outlaw street football pitches and improvised playing fields. The mission of the art collective was not only to provide information about these areas but to also bring about a discussion on topics relating to the re-use and reclaiming of city spaces.

Another creative use of data available on the web is represented in a video project initiated by a Tunisian cyber activist and blogger called “Astrubal”. He created a video work in response to the claims of the Tunisian Government that their president has only left the country three times in the past few years as he was preoccupied with important government matters. Astrubal investigated flight information available on the internet relating to the Tunisian presidential airplane. He collected images from various mapping websites, which identified the plane at specific locations and at certain times. The result of this investigation, represented in a video, proved that the president has been out of Tunisia far more often than stated and not on government matters, but on holidays and shopping trips, which are

funded by Tunisian tax payer's money. This project is a fantastic example of creative use of online data, which is gathered collaboratively by various internet users and combined in a video work, available through video sharing websites.

Another innovative model of online activism can be found in internet political mash-up sites, such as www.PublicWhip.org.uk and www.TheyWorkForYou.com. These websites provide information on the activities of the members of the United Kingdom Parliament and, more specifically, on their voting patterns, parliamentary debates, and expenses. All of the House of Commons and House of Lords debate transcripts are available online, however, via these websites, each member of the public can view summarized information for their MP and his or her activity without having to browse through hundreds of Parliament pages and newspaper articles. The creators of these projects work on a voluntary basis and their mission is to "...to help bridge this growing democratic disconnect, in the belief that there is little wrong with Parliament that a healthy mixture of transparency and public engagement won't fix." [10]

The internet has come a long way since the 1960's, when it began its existence as a Government project. It now provides various creative opportunities for activist art collectives to share concerns, viewpoints, and, essentially, engage the public in dialogue and actions prompting change. The global net is now a new public arena with enormous democratic potential for political and social action.

Final Thoughts

Patricia Philips defines public art and activist art as inseparable and, "...united in an inherently cooperative model of social-aesthetic practice." [11] According to this notion, art can be defined as "public" based on what it does, but not where it is located.

It is apparent that in the public activist art projects discussed above, the meaning of "public" is identified precisely via the messages that these works are trying to communicate to their audiences. Artists define their own commutative relationship with the public by observing, trying to understand our culture, and by producing works that challenge and provoke emotions; attempting to make us angry, make us happy, or, at least, make us think.

It has been more than 60 years since Orwell wrote:

They were born....they passed through a brief blossoming period of beauty and sexual desire, they married at twenty, they were middle-aged at thirty, they died.....the care of home and children, petty quarrels with neighbors, films, football, beer, and, above all, gambling filled up the horizon of their minds. [12]

Have we become more or less concerned with what is happening around us since then? It is perhaps not surprising that in the contemporary urban space, constituted of social and political power, artists and activist groups are trying to engage the public by provoking some kind of response calling for social change or simply raising awareness. I believe that a good artist is one who is aware of what is happening around them and who manages to translate their thoughts using the power of images, objects, technology, text, and performance. Site-specific interventions, product-hacks, and internet mash-ups are offering the public the opportunity to re-examine its relationship with the urban, social and virtual spaces.

I do not attempt to plead that all art should focus on activism or that the artists should only be concerned with political issues. I also think that it is unreasonable to expect that art can resolve major issues in the political or social sphere. What I do believe is that art has the power to help us imagine, think, understand, and care.

Art can be seen as a tool of communication with the other, but also as a tool of relation to the other; a method of conveying a message that otherwise may not be understood. Breakthroughs in technology have had a vast impact on the way activist art projects are initiated and developed. Furthermore, the internet, as a virtual public space, has presented the artists with an opportunity to organize and promote their practices. At the same time, I can't help but wonder if the increased use of virtual space has not affected the way we think about the physical public space. I do, nevertheless, think that being indifferent to our surroundings may put too much power into the hand of banks and corporations and restrict, even more, our right to enjoy the public places that belong to us - to the public.

MASS BODY INDEX: BIO-OS, A BIOLOGICAL OPERATING SYSTEM

Mike Phillips, Birgitte Aga, Gianni Corino & Simon Lock

Mass Body Index describes an ongoing project being developed by i-DAT called Bio-OS, a Biological Operating System. Bio-OS builds on the i-DAT's 'Operating Systems' (www.op-sy.com) [1] to develop open tools for gathering data from environments (buildings and landscapes) and organisms (crowds and bodies) to dynamically manifest 'data' as experience in order to enhance perspectives on a complex world.

Figure 1. Bio-OS Data Lab, 2011, i-DAT. CC BY-SA.

Figure 2. Human Internal Landscape, Ultrasound Pornography, 1988, Phillips, M., CC BY-SA.

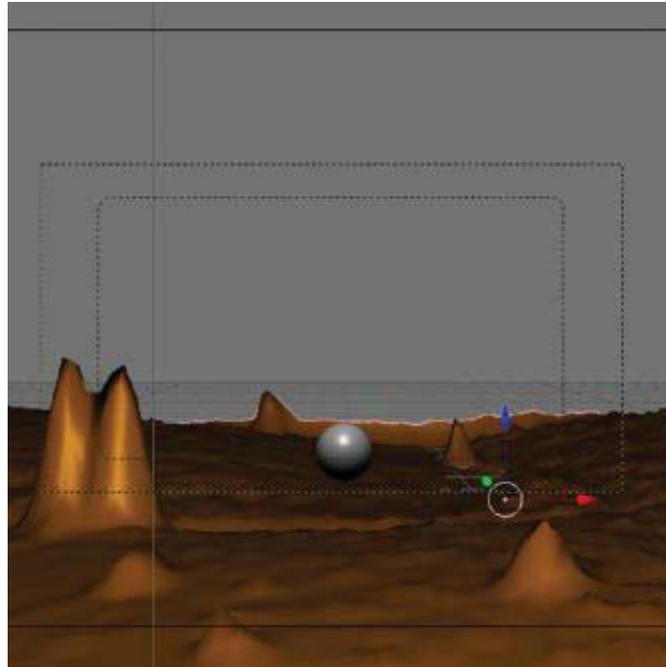

Figure 3. *Human Geography*, 2011, i-DAT, Atomic Force Microscopy Data in Blender Game Engine. CC BY-SA.

Isotonic Aids Recovery

In many ways, apart from the trauma of general bodily ownership or being owned by a body, 'Bio-OS' [2] was inspired by a longstanding collaboration with the Artist Donald Rodney. As much as it was a continuation of i-DAT's Operating Systems mission, Bio-OS built on the production of collaborative projects such as 'Visceral Canker,' [3] 'Psalms' [4] and 'Autoicon.' [5] Donald's death, in 1998, followed the a long slow degenerative disease of the Darwinian curse Sickle Cell Anaemia which caused his regular incarceration in hospitals and various medical technological apparatus. Donald's work political work was entwined with the attributes of this genetic decease, providing a rich palette of medical paraphernalia that became incorporated into his work, blurring the edges between a personal, racial and political heritage.

'*Visceral Canker*' (1990), now in the Tate collection, was a work that literally incorporated the artist's bloodline. Like many of his works, *Visceral Canker* contained elements of his own body, such as skin and scars. '*Psalms*' (1997), an autonomous wheelchair attempts to articulate the presence or lack of presence of the body. And '*Donald Rodney Autoicon*' (2000), a collaborative project Rodney was working on at the time of his death. The intention was to integrate his 'body' of medical data with an 'expert system' synthesised from interviews, and a rule based montage machine that would allow Autoicon to carry on generating works of art.

From the remnants of Donald's body, whether it was the politics of a bloodline, the space of an empty wheelchair that defined his absence or the attempt of Autoicon to continue the body of creative work, it was clear that the physical body is more than the material of flesh and blood. The body was defined by an absence, an event, a trace, a measurement and it was essentially performative and time based. It is this temporal fragmented entity that Bio-OS engages with.

The Mass Body index attempts to define a collaborative body that is neither ill nor super fit, but an aggregation. Whilst Bio-OS positions itself within the field of information visualisation/literacy, the generation and collection of bodily information through the use of instruments overlaps coherently with the history and contemporary fascination of body hacking. However, a preoccupation here is often with the body as object for adornment rather than an engagement with bodily process. Where the body hack converges with the performative it is often framed within the constraints of choreography. Bio-OS builds on a previous engagement with these frames and constraints.

Previous collaborative projects attempted to capture the body in the form of a Corporeal Archive. The idea of the corporeal archive emerged as a real time archival process that attempted to capture, articulate and disseminate 'unstable' 'difficult' or 'live' body-based media (particularly forms of dance, theatre, and performance art) through software and conceptual tools. The prototype '*Liquid Reader*' (*Liquid Reader™ v1.1*) [6] explored the reciprocal relationship between 'live' performance and its dissemination through other media, how ephemeral, body-based practices can be captured, analysed, shared and communicated. Here the temporality of the body was the focus of attention. Its spatiality was of importance but its transitions as a flow through time, a trace to be captured and communicated, became the important ingredient in understanding the dynamics, mechanics and physics of the physical body.

A historic fascination with the body, its mutability and its relationship to technology runs deep through the modernist machine aesthetic. The trauma of triage in World War One left more than surgical scars on returning troops. Like perspective and social order the nature of the body had suffered a significant rupture. No longer was the marble edifice of David enough to satisfy, the white exterior had fragmented into a car crash of flesh and bone popped inside out by munitions. The contemporary body freely melts into the technology that surrounds it as distinctions between body and instrument dissolve. The symbiosis evident/required in the cyborg is one of meat and metal, a Léger painting manifest, not one of soul and intelligence or intuition and logic.

As our instruments evolve from an isolated artefact, through physical and social networks into an all-pervading system or process, the nature of our relationship with them will inevitably change. There is now a sophisticated symbiosis between our instruments, and us, what happens to that relationship when the instruments we manufacture become ubiquitous and decentralised from hospitals and medical institutions. Imaging systems and digital instruments have revolutionised our relationship with the inside of our bodies creating a new pornography. This pornography is played out nightly on our TV screens, from House to CSI, or witnessed in the transformative marketing campaigns of soft drink manufactures. What reimagining of the body took place when a drink for sick old people became a drink for the super fit young people?

The Body - not, and, or, if...then, if and only if - ill/well

i-DAT is developing a range of technologies and software under its core program, 'Operating Systems' (op-sy.com). The current Operating Systems are:

- Arch-OS: [architectural operating system] An 'Operating System' for contemporary architecture (Arch-OS, 'software for buildings').
- S-OS: [social operating system] - The S-OS project strand provides an Operating System for social life.
- Eco-OS: [ecological operating system] - Eco-OS collects data from an environment through a mesh network of environmental sensors called ecoids.

- Dome-OS: Dome-OS is based around i-DAT's immersive vision theatre (Full Dome). A transdisciplinary instrument for scientific and artistic production of immersive environments and the manifestation of material, immaterial and imaginary worlds.

The intention of Bio-OS is to make the data generated by human biology tangible and readily available to the public, artists, engineers and scientists. The Operating Systems project explores data as an abstract and invisible material that generates a dynamic mirror image of our biological, ecological and social activities. The Operating Systems project proposes a range of tools and initiatives that have the potential to enhance our ability to perceive and orchestrate this mirror world.

Bio-OS builds on this open technical framework to offer the opportunity to collect and manifest biological data. Dynamic visual and sonic experiences derived from human movement are being tailored to enhance public understanding of the collective, mass biology. In this context Bio-OS and its distribution and engagement mechanisms provide an open tool for public engagement with a domain that is primarily owned by medical, scientific fields.

Bio-OS provides accessible tools (through 'hacks', wearable devices, phone Apps and domestic and public health technologies and social media tools) that are being deployed in daily life for monitoring health and activity. Data collected from these tools feed dynamic databases that facilitate a shared understanding of the mass body index through visualisations and sonifications – a data body culture of health.

The Bio-OS project is supported by the Arts Council England and was delivered through a series of 'Collaborative Data Lab's,' [7] in order to design and share 'instruments' or 'provocative prototypes' topically described as the 'Internet of Things', in this case the human body becomes a networked and shared 'thing'.

Bio-OS generates a rich mix of quantitative and qualitative data. Collectively these processes establish an open participatory 'techno-ethnography' - mechanisms for evaluating engagement and participation. It is the body as a temporal event and the trigger for a whole series of interactions that underpins Bio-OS as a platform. Here the body is seen within the context of numerous external frameworks and social cultural and economic systems. For instance, embracing the preoccupation of the Banking system where processes are based around key stages in the life of a body, birth, marriage, divorce and death (not necessarily in that order). Or the body on a more short-term basis, as the source of sewerage or food consumption around which provoke massive engineering, financial and ecological problems. As such, the body acts as an active node in a dynamic network, linking resources, technologies and social processes.

Human Geography

As a Mass Body Index Bio-OS intends to pervade these human manufactured structures by being part of the material of our shared understanding of our bodies and the collective body. Bernard Stiegler articulates the emergence of this new embedded technological landscape as a "global mnemotechnical system." [8] With such mnemotechnical system in place, information never leaves the world. It just keeps accumulating, simultaneously more explicit, more available, and more persistent than anything we have experienced. In this context Bio-OS strives to contribute to an emergent definition of interaction design strategies for spimes, sentient objects, blogjects or whatever they are going to be called. Bio-OS instruments become more than just biological probes, they emerge as cultural probes, permanently embedded in the body as part of the physical nature of the 'thing' and part of the physical digital ecosystem.

Figure 3. *Human Geography*, 2011, i-DAT, Atomic Force Microscopy Data in Blender Game Engine. CC BY-SA.

The body operates as conduits for exchange for ideas, knowledge and the passing of physical objects. The body is also a node on more problematic network, such as supply chains for food, traffic and amenities. Bio-OS explores the temporality of the body and the latency of the network of bodies and the impact on the environment. Bio-OS engages with the body and the ‘things’ that cluster around it through a process of participatory design of ‘provocative prototypes’ that will elicit real time data.

As such it is easy to see how the body becomes institutionalised. How the needs of servicing the organism, feeding, relieving and fixing it become instrumentalised and systematised. A de-humanisation or a re-humanisation? The shift from the body as the focus to the institution that builds up around it is a process of bureaucratic aggregation. Measuring and instrumenting a single body is intimate, a whole hospital of bodies is institutional. Bio-OS is pragmatically engaging with the implantation of instruments into these institutions in order to recover the ‘lost’ or aggregated body. Most notably through the inclusion in the development team of the E-Health and Health Informatics research group and the deployment of Bio-OS prototypes within the National Health Service Derriford Hospital (Plymouth, UK). For instance, the application of sensors to beds not only provides location (the number of misplaced beds is quite shocking) but also context (urine and temperature sensors can inform on bodily activities and occupation – the number of misplaced patients is even more so).

Without an appreciation of context, interpreting streams of bio signal data is fraught with difficulty. Consider for example attempting to interpret the pulse rate of an individual who is running to catch a bus, without knowledge of what they are doing or why. Human behaviours and external influences interfere with biological signals and can result in misleading data and lead to erroneous inferences. Instrumentation and recognition technologies are not yet sophisticated enough to allow us to accurately distinguish between different contexts. In order to reliably interpret bio signal data, our focus must shift from considering absolute values to the analysis of relative and somehow correlated values.

Data Body

One such approach to relative values is the use of signal coherence. This concept is easily illustrated with the use of a simple example. During physical exertion, both heart rate (pulse) and breathing rate (respiration) increases. Conversely, during periods of rest both readings will fall. The rates will depend on numerous factors, some of which are accurately measurable, others somewhat less so. As such, these absolute bio signal values tell us little about the health, fitness and general well being of an individual. What is insightful however is the relationship, interdependence and importantly the divergence between these values. This ‘coherence’ provides a much more sophisticated mechanism for interpretation, inference and understanding. Differences in the rate of change (during both increasing and decreasing phases) provide us with an accurate and reliable appreciation of human physical condition. By considering these relative values we can cancel out and remove much of the noise and interference caused by factors such as external stimulus, exertion and conscious control.

Baselines are another value tool in the interpretation of bio data. We can compare an individual's bio signal patterns with a previously recorded baseline set in order to determine variation and deviation. Similarly, we can perform comparisons of collective community patterns with that of community baselines. By comparing like with like (i.e. a community with itself) we can gain insight into the impact of

short-term events (e.g. illness, bereavement, or other major life events) as well as revealing longer-term trends (caused by aging, diet, environment, exercise regimes etc). More provocatively, we can compare individuals or communities with idealized baselines - allowing comparison and even competition between them and the most fit or healthiest individuals and communities. This provides us with a unique insight into previously unexplored aspects of group and community health.

Bio-OS will engage in the sharing of the Mass Body Index using a similar paradigm to the recent Open Data governmental initiatives (for example in London and Manchester). These attempts by local and regional government to make their activities, achievements and deficiencies open and transparent have had the effect of revealing (anonymised) data regarding the attributes and behaviours of individual citizens and communities. Bio-OS harnesses the technological infrastructure developed for use with Open Data (namely Resource Description Frameworks, Triple Stores, SPARQL etc) yet with a grass roots, "bottom up" and voluntary ethos. Individuals and communities self-exposing their own Bio signal data in this fashion would result in a culture not unlike that which Sousveillance has achieved within the realms of audio visual data - an evolution of body instrumentation and institutions that smother it, and a further exposure of our most intimate parts.

THE CHOREOGRAPHIC HORIZONS OF ISABEL ROCAMORA: “INCALCULABLE” EXILES

ANNALISA PICCIRILLO

In the workshop “Exile Writing”, we explored the question of exile in its multiple technologies. Here, I would like to present a technology of writing that specifically relates to the body: contemporary choreography. The example of the video-dance *Horizon of Exile* (2007) by I. Rocamora will help me to discuss how ‘dance’, ‘exile’, ‘writing’ and ‘femininity’ intertwine in creating the alternative “horizons” provided by the video digital support.

Writing/Choreography

I would like to introduce, with a lapidary definition, what I mean by ‘choreography’. I will quote a statement by the French-Algerian philosopher Jacques Derrida, in his *Writing and Difference* (1978):

And thus we say “writing” for all that gives rise to an inscription in general, whether it is literal or not and even if what it distributes in space is alien to the order of the voice: cinematography, *choreography* of course, but also pictorial, musical, sculptural “writing”. ... All this to describe not only the system of notation secondarily connected with these activities but the essence and the content of these activities themselves. [1]

Beyond its ‘differences’ – historical traditions, multiple styles and incalculable expressions – ‘choreography’ can be defined as a system of signs always ‘differed’ and ‘dislocated’ in time and space. It is an embodied language that reveals a *technè*, a technology, a shared knowledge of gestures, and a system of memory apt to remember. Its privileged instrument is the body, what writes and expresses its own textuality, with all its “incalculable” differences and all its “incalculable” choreographies.

INCALCULABLE CHOREOGRAPHIES

“Incalculable choreographies”: I borrow the expression from the interview conducted by Christie McDonald to Jacques Derrida, where the philosopher is invited to talk on sexual difference, and on the “place” of the feminine in contemporary social-cultural representation. Beyond any binary opposition, beyond the masculine/feminine that governs the decorum of codes, Derrida dreams of – and believes in – the “multiplicity of sexually marked voices ... mobile and non-identified sexual marks whose choreography can carry, divide, multiply the body of each ‘individual’ ...”. In his conclusion, he remarks:

Then too, I ask you, what kind of a dance would there be, or would there be one at all, if the sexes were not exchanged according to rhythms that vary considerably? In a quite rigorous sense, the *exchange* alone could not suffice either, however, because the desire to escape the combinatory itself, to invent incalculable choreographies, would remain. [2]

Fascinated by Derrida’s expression, I will use it as a deconstructionist ‘trope’, in order to disseminate the meanings of the dancing event; in order to investigate the interaction of multiple bodies in a live dance

performance or in a video-dance work; it will possibly allow me to observe its encounter with the ‘other’ and its alterity.

FEMININE WRITING

One of my aims is to investigate how ‘dance’, ‘writing’ and ‘femininity’ intertwine; along this focus, it is Hélène Cixous who provides me with theoretical and methodological tools. The French feminist invites us to explore the sources of otherness in the female body, by stating the ‘hospitality’ of writing as a privileged space for manifesting women’s agency and physicality. In *The Newly Born Woman* (1986) and in “Coming to Writing” (1991), Cixous brings the matter of physicality into writing: “When I say “writing” seized me, it wasn’t a sentence that had managed to seduce me, there was absolutely nothing written, not a letter, not a line. But in the depths of the flesh, the attack. Pushed. Not penetrated. Invested. Set in motion.” [3] Cixous’ insistence on the physicality of the writing body seems to imply a direct relationship between the female body and “feminine writing”. The work by Isabel Rocamora is an example of such “feminine writing” – where exiled women find hospitality by means of the technology of video-dance. Her choreographic writing hosts exiled voices and bodies; her is the space where women can share, elaborate and, possibly, overcome experiences of displacement and, finally, acquire an identity ‘in suspension’.

Isabel Rocamora: *Horizon of Exile*

Isabel Rocamora (1968) was born and brought up in Barcelona by an English father and a Spanish mother. She has been based in the U. K since 1986, and she now is working between London and Barcelona. Graduating in Performance and Cinema Studies from Bristol University, her practice has developed throughout performance, live mixed media and artistic cinema, centered on a rigorous investigation on the performative language of human gesture in its relationship to individual and cultural identity. [4] A technique of aerial movements distinguishes Rocamora’s dance – better known as “anti-gravity choreography”. The author says: “It uses the hanging body and its ‘subversion’ of gravity as a metaphor for changing states of consciousness, paralleling the experience of weightlessness with freedom from the rational. Distinct from zero/micro gravity (as experienced in parabolic flights), anti-gravity performance needs the force of gravity to move against.” [5] In Rocamora’s work, slowness, stillness and anti-gravity forge the movement of the dancing bodies to re-elaborate and negotiate dance’s ontological essence: it is movement itself:

As an anti-gravity artist I have spent the last ten years experimenting to push the boundaries of what the body in suspension is able to do. During these investigations one opens up areas of the body that were previously tightly held. At the point of opening one may feel the release of an experience, a memory, an emotion that had been housed in that area for years. [6]

Horizon of Exile, a 2007 video-dance work, follows the exile journey of two veiled women across timeless deserted landscapes. The testimonies of Kurdish and Iraqi women, living today in London, inform the unfolding of the narrative; alongside are the stories of two older women, themselves exiled, and local to the landscapes of the Atacama desert, in Chile – where the film is actually shot. The chorus of these voices carries, on the one hand, strong memories of the female circumcision, erasure and escape, and on the other hand, it provides the images of a distant childhood home. The female body writing intertwines with the live memories: the live experiences of exiled identities forced to leave their countries

in order to protect a sense of themselves. *Horizon...* talks of a double exile: in one of the video sequences, a spectral female voiceover insists: “Our existence is wrong, being a woman is wrong, it’s like that”. Some of the voices were recorded in England, as if to reveal a second exile, the one that joins with the ‘internal’ exile that being a woman signifies.

Rocamora’s Voice

Positioning itself between the cinematic, the real world and performativity, Rocamora’s work sits between fiction, representation and the metaphor – this creative overlapping mirrors her own personal experience:

These resonant narratives awake a personal desire to treat complex feelings surrounding my own story of exile and self-finding at the age of eighteen (Spain – U.K). While reflecting female Middle Eastern experience of exile and drawing an understanding from my own autobiographical material, *Horizon* is foremost an installation about woman and identity.

Faced with issues of first person representation (Middle Eastern woman from a Western perspective) and wishing to present an essence rather than a given cultural context, I have chosen to construct a fictive character and environment which are drawn from various common denominators: Palestine (lead performer), Central Iraq/ Kurdistan/ Iran (interviewees), Jordan (nomadic desert culture), trans-national Bedouin/ Iran/ Jordan (costumes), Saudi Arabia (call to prayer) and Armenia (music). [7]

In occasion of an informal conversation, the artist told me of the inner drive that pushes her to give voice and movement to exiled/veiled women. She was educated in a private school by nuns; thus, in her childhood, she had a familiar and accustomed understanding of female veiled bodies. After the London bomb terroristic attacks in 2005, an uncanny change took place: Rocamora’s perception of the ‘veiled body’ transformed – no matter what race, religion or ethnic group, she began to perceive those ‘veiled’ bodies as unfamiliar, as if her gaze was beginning to interiorize the fears and stereotypes intersected to the veil. The veil’s issue is complex and impossible to discuss here; still, I find interesting to see how and why Rocamora decides to challenge and re-elaborate the image of veiled bodies’. In her coreography, she offers us her re-vision, her “horizon”, of veiled identities.

I will extract three sequences, three “incalculable movements”, from Rocamora’s work, in order to show the exact places where, in my reading, the essence of exile writing/choreography comes to be realized; the exact loci where the female quest for agency becomes visible.

THE SECRET BEHIND THE VEIL

In the first sequence, the dancer looks into the camera – it is the moment when she meets our ‘other’ and privileged gaze. In this situation, the confrontation with ‘the other’, allowing for self-recognition, remains ‘suspended’ through the use of the veil itself. Slowly, the dancer covers her face – she performs the act of hiding. We cannot see; our western gaze cannot understand what lies behind the veil, incapable of grasping the weight of private sorrows, the pains and the losses carried by the woman’s timeless and ‘incalculable’ journey into exile. There is there a secret: what lies behind the veil is ‘incalculable’.

'COUNTER-DANCE'

The second sequence is when two dancing bodies, sitting and falling in a vast scape, betray a 'serene' violence. A flux of primitive energy seems to drive the scene. The choreography is developed through gestures of resistance and subversion. A "counter-dance" is displayed: the women seem to fight with/for their bodies, in order to release a natural instinct, to liberate a prohibited sexual instinct. At this stage, Cixous' call "to write" would resound; her writing becoming the flesh of the two dancer's bodies in subversion:

Write your self. Your body must be heard. Only then will the immense resources of the unconscious spring forth.... To write. it will give her back her goods, her pleasures, her organs, ...; it will tear her away from the structure in which she has always occupied the place reserved for the guilty (guilty of everything, guilty at every turn: for having desires, for not having any; for being frigid, for being "too hot"; for not being both at once; for having children and for not having any; for nursing and for not nursing. [8]

BODIES/IDENTITIES 'IN SUSPENSION'

The third chorographical movement is visible at different stages of the work as if to reveal the signs of Rocamora's writing. Exile writing is embodied in the 'anti-gravity choreography' manifested in the rolling bodies of the protagonists. The anti-gravity body moves through space, travelling as if it encountered no resistance: "as if the matter of the body itself was no different from the air that is moving in, as if it were rising and descending at one and the same time." [9] In the apparently 'silent' space of the desert, Cixous's writing would resonate once again, seeming to choreograph, comment and be carried along by the dancers' movements:

She doesn't "speak", she throw her trembling body into the air, she let's herself go, she flies, she goes completely into her voice, she vitally defends the "logic" of her discourse with her body; her flesh speaks true...she conveys meaning with her body. [10]

In *Women of Algiers in their Apartment* – original title: *Femmes d'Alger dans leur appartement* (Paris: Des Femmes, 1980) – the Algerian writer Assia Djébar asks us not to forget that "even those bodies who have been incarcerated, no matter what their age, class, or race, may have imprisoned bodies, but have souls that move more freely than even before." [11] In the ending of *Horizon*, the veiled body is near the bank of a river or the shore of a sea; here, the woman encounters water, slowly starting to "unveil" herself. It is the water to choreograph her body; liquidity becomes the matter, the matrix, and the material of her subversive writing – the space of her survival and of her expression. The act of self-affirmation in water depicts her agency, the movement of her choice – "freely than even before", as Djébar would say. In the kinetic dynamism of anti-gravity, and in the poetical suspension of the body, her female identity is able to find a new place, a new home, a new "horizon", and a new hospitality...

I would like to conclude my comment to this singular example of "exile writing" with the concept of "hospitality". Rocamora chooses multiple places in order to choreograph exile: as a language and as a technique, dance itself makes its journey towards other technologies and other languages; it is choreography itself to 'exile' towards the video technology.

An act of hospitality can only be poetic

(J. Derrida)

The hosting of dance on the screen provokes specific reflexions. Video-dance differs from a typical live performance because of the multiple features interacting on the digital support. In the first instance, the dancing body is perceived as hyper-visible in being re-presented and re-visible in the time and space “a-venir”/“still to come”. With its gestures, the body seems to acquire a ‘spectral’ dimension – since its performative act experiences the temporal disjunction in a given moment that does not belong to time any longer; it actually returns when we “recall” it in a specific time and space. It is how digitality challenges the so – called ‘ephemeral’ value of live dance performances – the dancing gesture does not disappear once it is done, but it ‘lives on’ differently inside the ‘spectral’ dimension of the digital screen. [12]

Here the discussion could be very productive if we think of digital dance; if, for instance, we might consider here the “motion capture” technology so widely used in contemporary dance. Still, this would take us along a complex path; what we can rather say is that, on the other side of technology, still as its own countersignature, the histories of female displacement find a fruitful hospitality in natural spaces. In *Horizon...* two women leave the urban space, a ‘still’ space, the space of law and convention where the masculine power penetrates all intimacy from the minaret; they move to the Atacama desert, which, in its landscapes made of ice, vapour and sand, materializes the projection of the two women’s interior spaces. The desert and, in the end, water signify an undefined place, possibly arid and vacuous, possibly devoid of points of reference; nevertheless, it is open enough to be crafted by the act of theatre, fertile enough to host the act of female agency. Water is the last horizon; in its impossible frame because too fluid, the dancer restages the wonderful *Ophelia* by John Everett Millais (1852); like the Shakespearean figure, the woman-dancer, ‘suspended’ there, can affirm her freedom. In this work, nature really hosts female writing – the desert and water absorb the bodies, the traces, the memories – the “incalculable choreographies” of their exile.

“INCALCULABLE” EXILES

There is still one last consideration to make: the journey of Rocamora’s exiled bodies reminds us of the dance of contemporary ‘real’ exiles, which might be part of the ‘choreography’ of the not-yet-elaborated trauma experienced nowadays by the European collective memory – specifically, by the Italian memory. The Southern coast in Sicily are witnessing the infinite migrating flows of people, carried by innumerable boats, who arrive from Northern Africa to Italy through the Mediterranean Sea. In these ‘incalculable’ transits, the image of the female body is often absent, even more ‘suspended’, because of her in/visibility. In this time of ‘historical myopia’, we should start interrogating the ‘veil’ covering our own western gazes (predicated on their certainty and belief in absolute knowledge): it might be the necessary way to have an insight into our historical and political contemporary ‘choreography’.

Hospitality is culture itself and not simply one ethic amongst others. Insofar as it has to do with the ethos, that is, the residence, one’s at-home, the familiar place of dwelling, as much as the manner of being there, the manner in which we relate to ourselves and to others, to others as our own or as foreigners, ethics is hospitality; ethics is entirely coextensive with the experience of hospitality, whichever way one expands or limits that. THE ESTONIAN EXPERIENCE: NON-INSTITUTIONAL MEDIA ART PRODUCTION IN ESTONIA

Piibe Piirma

Speaking about media art in Estonia at the present moment, I will bring out 4 main lines (DIY phenomenon, financial situation, blending of various forms of culture, artist's ironic attitude and manipulation with media), which characterize current media art in Estonia and show us, that Estonia has adopted developments underway elsewhere and thus media art is also moving strongly forwards.

Artists have always been curious and open to implementing new opportunities. The rapid development of new technologies has given us fantastic possibilities for expressing ourselves in a modern way, and one cannot underestimate the role of media art in our society. By indeed belonging to the group of "Eastern-Bloc Countries" in geographic terms, we can boldly say that Estonia has adopted quite quickly developments underway elsewhere and thus media art is also moving strongly forwards. This has certainly been helped along by an open society and constant expansion of opportunities. This has certainly been helped along by an open society and constant expansion of opportunities – Western countries' artists' interest in what happens in Estonia and efficiently functioning international contacts.

About the past and present of Estonian media art in brief

Speaking about media art in Estonia at the present moment, I can boldly claim that the media art being created is, for the most part, indeed non-institutional and quite self-generating. We nevertheless also have our own historical heritage, the roots of which stretch back into the 1960's (for example experiments in pop- and kinetic art etc). However, a new wave of media art arose in the mid-1990's, when Estonia accepted the Internet as a new tool of creation and when barriers between Estonia and the rest of the world disappeared. During this period appeared the pioneers of 'net art', who actively and freely began asking questions about computer gender (Mare Tralla, e-mail questionnaire and first web pages), the possibilities of social networking (Raivo Kelomees, "Cybertower") and hypertextual poetry on the Internet (Nelli Rohtvee). The majority of media art in the 1990's was created at the initiative of the students and faculty of the Estonian Academy of Arts. The reasons why artists interested in media art at the time carried out activities at the university are simple - a computer class equipped with Internet capability was created at the Estonian Academy of Arts. The E-Media Center was established in 1994 by the initiative of artist Ando Keskküla. In 1995, artists Ando Keskküla, Sirje Helme and Eric Kluitenberg carried out our first international conference "Interstanding – Understanding Interactivity".

In the present age, where Internet and computers are available to everyone, media art is arising in small groups that do not depend as much on a university or official creative organizations - interest-based groups indeed are formed on many occasions by former new-media university students; however fertile activities still take place by artists' own initiative.

What characterizes non-institutional media art in Estonia?

While speaking of non-institutional media art production in Estonia, I rely upon my personal experience organizing the annual media art festival 'Plektrum' in Tallinn. The festival was conceived just as are many good ideas in the world: in a small suburban attic apartment, where young people decided during a gathering of friends to create a festival of club parties. The small party has grown to this year's already ninth-annual, ten-day-long festival comprising music, exhibitions, audio-visual experiments as well as organized initiatives in public city spaces. The fact that makes it fresh and youth-oriented is that festival organization is controlled by young volunteers, students are allowed to speak at exhibitions and a great number of greater- and less-known figures are able to come before the public with their projects. It is foremost a meeting place for professionals and amateurs that certainly does not solve the large problems of media theory, but which showcases significant trends.

Art events and workshops that have taken place at the festival over the years superbly exemplify the DIY phenomenon that I regard the first characteristic feature of Estonian media art - art projects and workshops transpire with low-tech resources, using a hands-on method. The availability and simplicity of technology, which enables us to function almost without boundaries, is the most important aspect in the activities of contemporary artists. It is not a question of a lack of topics or the complexity of tools, but rather the limitation of capabilities and time to ourselves.

The second important aspect of characterizing Estonian media art is problems financing it. Naturally, we possess support structures that also support good projects when necessary; however they do not number many and I believe the constant search for new, alternative opportunities has by and large even benefited art. This leads in turn to looking for cooperative possibilities with foreign partners and the desire to also acquaint one's activities outside of Estonia's national borders.

The third attribute that characterizes our contemporary media art is the dissolution of various forms of culture. Software programming and innovative technological solutions have mixed actual creative works with coordinated events, actual communication holds an important place alongside that done on the Internet and everything seems to be permitted. Therefore it is often very difficult to determine, from what point one is dealing with software art and from what point it is performance or some other phenomenon. This is, of course, not a unique experience for Estonia alone - the blending of mediums is happening everywhere. Yet the fact that cooperation in the field of culture is functioning wonderfully between Estonians from creative backgrounds and those from other walks of life demonstrates greatly that Estonian artists are closely following developments elsewhere and are capable of locating their activities within a wider context.

The fourth phenomenon that I can certainly regard as characteristic for Estonia is a certain joyfully ironic attitude towards widespread problems. Work performed with media artists and exhibition curation has shown that fears and taboos become a part of humorous commentary rather than heavy philosophical discussion. An interesting paradox surfaced while putting together the exhibition "Transparent Generation" in 2008 - the issue, which elsewhere in the world has become popular, did not incite works with fear or negative undertones in the least; our artists regarded the topic rather with happy superiority. Through the works, we found that surrounding cameras and carefully-checked personal data is an unavoidable part of contemporary society with which one must come to terms, and which must be utilized in the very best way in art. It is worth noting that a review of the exhibition in a major Estonian daily newspaper was given the headline: "What the knowledge that Britney Spears is pregnant gives us". Following this, the article, which was published in the online press, received an immense number of views and proved in a lively fashion that manipulation with media is one part of our culture.

In summary

The current age shows clearly that Estonian media art is generated through very practical activities regardless of the existence of a definite institution. Several artists using new media as a tool today originate from very different fields of life and thus provide media art with ever newer interdisciplinary dimensions. At the same time, the annual festival undoubtedly helps to boost the reputation of media art, to allow people to grasp the coexistence of art and technology as a whole, to work and brainstorm actively in this field. And the most important aspect it helps to foster is the meeting of interest groups.

Estonia has certainly done a great amount of work in the IT sector, however cultural figures must be successful, taking into account their few opportunities. As a small and quite poor country, we are in a situation in which the act of making art and especially "underground" manifestations must successfully make do on their own. On the other hand, such a situation directs one towards greater creativity that is not dependent on material values - towards establishing exciting cooperative groups, high-volume and constant self-learning as well as searching for international contacts.

Nevertheless, I find that the current age provides us with fantastic opportunities because we live in an environment where a high number of both technologies and cooperative networks are at our disposal, several diverse kinds of events take place and all ideas may be realistically feasible in the context of media art.

THE RHETORICAL ART OF DATA VISUALISATION

JEREMY PILCHER

Art that visualises data is commonly understood to enable a transparent understanding of a large amount of factual information. I argue that art which employs such a technique may also be understood to critique the value-systems and hierarchies of importance that give rise to the networks and data flows that are visualized. Art may open an engagement with what society has to occlude in order to maintain its existence without change.

Data visualisation techniques have been used by artists as a means to critique society, and in particular capitalism. Such art is often understood in terms of the reduction of an overwhelming amount of data to a meaningful representation. The availability of data, and its visualisation, is attributed with improving greater transparency and accountability of the systems that structure our lives. It is commonly regarded as desirable that the way in which data is presented should be transparent. [1] Data visualisations are understood as evidence of, and as an explanation for, the world. So called ‘new media art’ is regarded as a particularly effective site for such visualisations because of the opportunities it provides to interact with the underlying data.

It is arguable that a transparent representation of affairs as they exist is, in itself, not a critique of how things ought to be. The work of Arthur Danto provides an approach to art that responds to this issue. He argues that art that employs factual data does more than represent the world; it expresses a point of view about the content of the work. However, Danto’s argument is weakened by maintaining a distinction between the form and content of art. Instead, starting from Derek Attridge’s understanding of the work as a performative event, I will explore how art may provide the opportunity to acknowledge that which must be ignored by any given society if it is to remain unchanged. My argument is that, approached in these terms, interaction with data may uncover the contingencies in the way societies are constructed.

They Rule

My argument will be progressed by engaging with *They Rule*, [2] which is an activist work of art by Josh On that has won a number of awards, including the Dutch Electronic Art Festival in 2003. It provides the viewer with the opportunity to interact with data about some major institutions and the boards of directors of the top 500 companies in the United States of America. The work exists in two versions, which respectively incorporate static data collated in 2001 and in 2004. This is clearly acknowledged on the site, which states that “*They Rule* is NOT a Live database of board members and companies. That information changes constantly. I hope to update the database annually, and try to ensure that the links are accurate at the time of launch.” [3]

Each of the companies included in *They Rule* is represented by an icon of a company board table, which appears on screen surrounded by avatars representing the directors on the board. The size of an avatar reflects the number of company boards on which a director sits. As icons and avatars are clicked, the work allows connections between companies to be traced by the construction of network diagrams. It is

possible to discover, for example, that “the members of the boards for the so-called competitors Coke and Pepsi actually sit together on the board of a third corporation, Bristol Myers Squibb.” [4]

The Representation of Data and *They Rule*

Christiane Paul describes how the work may be understood to employ technology against companies using the Web as a marketing tool, which “turns us into transparent customers.” [5] The subversive effect of the work is commonly understood in terms of a greater understanding of the world as it exists. It has been observed, “If only the economic realities it depicts were as transparent and intuitive as its navigational structure, this would be a more benevolent world. The ease and transparency of the design layout, combined with an intriguing subject make *They Rule* an exquisitely idiosyncratic icon of activist web-design. Visit it today before They Outlaw It.” [6]

Yahya M Madra explicitly contextualizes Josh On’s work in terms of a critique of capitalism: “In *They Rule*, the moment of appropriation, in its exploitative capitalist form, is represented as a system of networks. While ‘they’ do have proper names, what is represented here is not particular individuals, but rather ‘they’ as a collective of appropriators.” [7] However, directors qua directors are company employees. As such, it may be questioned whether networks of directors should be regarded as an underlying class of appropriators. In terms of global capitalism, my view is that the term “appropriators” is better reserved for the shareholders and their interconnecting portfolios of company shares. Such shareholders will include not only individuals, who may also happen to be directors, but also other companies.

The important aspect of Madra’s description is the attention it draws to the work as a systemic critique. The work focuses attention on a feature of the legal system of the United States of America. *They Rule* does not reveal that companies will always have boards of directors that are interlinked. It enables people to realise that companies may, but won’t necessarily, be connected in this way. *They Rule* illustrates that there are some directors (of companies recognised by the law as separate legal personalities) who sit on more than one board and, in the process, connect competitor companies. However, as an exploration of the work reveals, there is no guarantee that links between companies will be found. Indeed, it is entirely possible that even when networks of boards of directors are identified from *They Rule*, neither these nor even the companies, will still currently exist.

The content of the database employed by the work is fixed at given points in time. Accordingly, many of the connections it is possible to identify by using *They Rule* are out of date and may even have been so at the time it first appeared online. The implied premise of continuing to understand *They Rule* as having an impact is that, irrespective of whether the individual networks depicted remain in existence, the work enables users to visualise specific networks that illustrate an ongoing feature of the economy, which is permitted by company law. My argument is that the critical force of the factual representations of data in *They Rule* lies in the exploration of the underlying legal system through iterations made possible by the work’s interface.

The Art of *They Rule*

They Rule, through depicting factual information, has been understood to reveal that there is something wrong with capitalism, or perhaps more specifically with the legal system of the United States of America. The existence of any specific network of directors may be unknown. However, the generic existence

of interconnections between boards and even the widespread extent of such links is not a revelation. This feature of the legal system of the United States of America has previously been identified and understood without the interactive creation of network diagrams. It is not immediately apparent that *They Rule*'s features, such as the manipulability and interactivity of the work's data, make it significantly different from other diagrammatic representations of historic data about a given state of affairs. Understood as art and approached through the work of the philosopher and art critique Arthur Danto, *They Rule* might be regarded as the expression of a value judgement. This would involve arguing that the work goes beyond representing the world as it is and visualises the point of view that it is wrong for a legal system to allow the formation of networks of interconnecting companies.

In 'The Transfiguration of the Commonplace' Arthur Danto engages with what distinguishes representations, such as diagrams, from works of art that may be visually indiscernible from such images. He argues that an artwork must be about something, which is to say that art expresses something about its content. In art there is a "double role of representation and expression" that must be engaged with when interpreting the work. [8] Artworks not only depict content, they also "project a certain point-of-view about whatever they are about. Whereas mere representations aspire to transparency, artworks express ideas and attitudes toward whatever they represent." [9] Approached in terms of Danto's argument, art that employs diagrams manages to do this, at least in part, because of the connotations diagrams have in our culture due to their use in disciplines such as economics and engineering. Understood in terms of the diagrams constructed in *They Rule*, the work simply represents the links between companies. However, as an artwork *They Rule* expresses condemnation of the interconnectedness of companies and their directors.

Danto's argument is an intriguing one but it raises a number of questions to which satisfactory responses are not provided in 'The Transfiguration of the Commonplace'. It is not clear to me that an account of *They Rule* in these terms provides a means to understand how, or indeed why, it is regarded as expressing a value judgement about the fact that company boards interconnect through directors. In addition it is possible to argue that the attitude expressed toward the content of the work does not itself escape from being part of the content. It is what might be described as meta-content or content about content. Danto briefly acknowledges this issue and reflects on the possibility that, when any representation is in some way self-referential, it will be an artwork. The task of examining content for the point of view expressed in it may recede away without end. Danto identifies this as a significant problem and suggests only that "the question in this form has not, to my knowledge been raised before in the entire history of the philosophy of art" [10]. My argument is that these issues may be engaged with through the work of Derek Attridge, which he explicitly acknowledges is much indebted to that of Jacques Derrida.

A Legal System Less Violent

In the 'The Singularity of Literature' Attridge argues that art works should not be understood instrumentally as communicating meaning, but rather as events that give rise to new meanings and feelings. Despite the title of the book, and the fact that much of his argument deals specifically with literature, Attridge makes it clear that he considers his work is applicable to art in general. He proposes that works should not be understood in terms of an opposition drawn between form and content or meaning. Instead, Attridge understands art as "bringing into existence a configuration of cultural materials that, at least to a certain group and for a certain time, holds out the possibility of a repeated encounter with alterity." [11] Viewers respond, not to "an attribute or a substance, but to an event: more clumsily we

could speak of the performing of narrativity, metaphorizing, imitating, describing.” [12] The focus is moved away from a concern with the extraction of a work’s meaning toward an engagement with it in performative terms. Art stages an opening with that which an existing cultural order has to disavow in order to be able to continue without change.

Approached in terms of Attridge’s argument the critical force of *They Rule* may be understood in terms of the way in which it opens an awareness of the violence of the law. More specifically, this manifests in the way that the legal system of the United States of America allows companies to interconnect through their directors. My argument in this respect starts from the way that the work invites the focus of attention to be widened out from the factual accuracy of the data visualised to include the process of how that data is explored. The fixed nature of *They Rule*’s database, the concomitant datedness of the data, and the way in which the identification of the extent and nature of connections between directors is contextualised by the links that cannot be traced, all make the work weak when understood as a set of factual representations of networks.

The effect of the characteristics of *They Rule* is that it may be understood to hold the data as a fixed given, which directs attention towards the way in which meaning is constructed by means of the selection and manipulation of data to create visualised networks. The screen quickly becomes cluttered with data after expanding a few companies’ boards. Directors with no contacts between the companies selected to be searched need to be deleted from the screen. In the process of locating networks of interconnecting boards of directors users are, in effect, compelled to be selective about the data that remains in sight. In the event that users want the remaining data to appear in the form of a visually appealing diagram then the icons and avatars that remain, together with the lines that connect them, have to be moved around the screen until the desired pattern for the network is achieved.

There are many fascinating diagrams saved on *They Rule* but it should not be forgotten that not all investigations using its database result in establishing the existence of network connections. I propose that the critical force of *They Rule* arises out of the process that users work through to identify and construct the visualisations of connections between (competing) companies (that have been) permitted by the legal system of the United States of America. The work invites users to focus on the interface to, and the interaction that it provides with, its database. It opens the opportunity to reflect on the multiple visual iterations of data derived from a legal system. *They Rule* directs the attention of those users who repeatedly explore the work’s databases toward the legal system that underlies all of the visualised data. In the process it stages the chance of judging whether it is just for the networks that are identified to (have been allowed to) exist.

The work may be understood to open an engagement with justice because *They Rule* stages an aporia in which every legal system is entangled. All laws are necessarily applied at times that are different from those at which they were formulated and brought into being. This means that any given law will need to be applied in specific individual situations, not all of which can be anticipated. As Derrida points out “Each case is other, each decision is different and requires an absolutely unique interpretation, which no existing, coded rule, can or ought to guarantee absolutely.” [13] The problem is that, in addition to being applied in specific situations, laws are also required to be general enough to allow them to be enforced equally and in a way that is not arbitrary. [14] Legal systems will always need to make efforts to recognise the specific circumstances of each case so as to enable there to be justice despite the generality of the law. However, ultimately it is impossible for decisions to be made as to the legal merits of every case on an individual basis whilst at the same time maintaining the universality of the law.

The more established and general laws are the more apparent become the difficulties associated with trying to reconcile the general with the particular. In broad terms, the laws that enable companies to be brought into existence and provide the framework within which they are operated are well established and accepted in the United States of America and other countries around the world. The inevitable violence of the law is in the way it asserts the authority to determine what is generally acceptable and to demarcate when exception(s) will be permitted in the name of justice. *They Rule* enables the visualisation of iterations of combinations of companies and in doing so opens an opportunity to evaluate this violence. This is because it provides the opportunity to consider the (im)possibility of a legal system that is general enough to apply equally and at all times to all directors, whilst at the same time being able to respond to specific circumstances that may mean that connections between companies are entirely legitimate and justifiable. *They Rule* invites reflection about whether the law could be less violent and in the process become more just. The force of *They Rule* is in the way that it directs critical attention, from outside the legal system, to the application of the law and the inevitable violence of the contingent boundaries it establishes.

Conclusion

I have sought to argue, through an interpretation of the work *They Rule*, for an approach to art that employs data visualisation that goes beyond understanding such work as a transparent depiction of content about the existing world. My aim has been to engage with *They Rule* both in terms of its factual content and by identifying the significance of the interface that has been provided to its content. The work enables the creation of visual iterations of networks made possible by the laws of the United States of America. This process invites users to become aware of the (im)possibility of a legal system that can be sufficiently general to be both fair and equal for all and at the same time able to make exceptions in specific cases. Attention is drawn to the violence of the legal system of the United States of America in the way it claims the authority to create and enforce the regulations that govern the way in which such an aporia is to be resolved. As such, *They Rule* stages an opening with that which an existing system has to disavow in order to be able to continue without change. While the law must necessarily be violent, when the possibility is raised that the law could be articulated differently and “grounded on less arbitrary modes of authority”, there is always scope for a more just legal system. [15] The political impact of *They Rule*’s visualisations is to unsettle claims to transcendence by the law, and in so doing open it to transformation by those it presently excludes.

DIGITAL AND INTERACTIVE CHOREOGRAPHY: INNOVATIVE WOMEN IN THE DANCE HISTORY

LUDMILA PIMENTEL

We are interested to describe, analyze and propose to dance a new concept: the concept of Interactive Digital Choreography. So our focus is in the digital choreographic possibilities with interactive quality, and contributions and new ideas proposed by women who participated in the recent history of Interactive Dance.

Fig. 1. Bluebody, 2008, by Ludmila Pimentel and Mariana Carranza, interactive installation, Copyright Ludmila Pimentel.

Fig. 2. RGBodies, 2008, by Ludmila Pimentel and Mariana Carranza, interactive installation, Copyright Ludmila Pimentel.

The Interactive Digital Choreography explored in this work shares some features with Interactive Art. We consider that the concept of Interactive Art comes from a continuation of the artistic movement advent of interactive installations that arise with the first facilities of videos installations that team together with *happenings* and conceptual art; all of them are part of the artistic movement of the 60s.

To understand the Interactivity of contemporary events we need to understand the events that happened in the history of art since the beginning of 20th century with Futurism, and continued with Fluxus, Process Art, Kinetic Art, Conceptual Art, until the contemporary stage of Art and Technology. We need to understand the collaboration of the work of John Cage, Robert Rauschenberg, Nam June Paik, also the new concepts proposed by Cybernetics, and of course the progressive 'dematerialization of the art object', which involves the active and physical public 'participation' in the event.

So, considering this context we need to mention the contributions of Allegra Fuller Snyder [1] that in 1965 proposed three distinct categories of dance and film. One would be the simple recording of a dance, where with just one camera, and also just a unique point of view, the dance danced on stage was recorded, another is the documentary film category of dance, where the narrative is respected but dance is adapted to film by using the camera close-ups, made distinct, and other technical capabilities, and more cameras available, and finally the cinedance, or 'choreocinema' (a term proposed by John Martin), [2] that is the creation of a new art, which can transcend the biological potential of our gravitational body and where it was introduced, according to Snyder, new possibilities of the body. Last category is the one most closely related to the topic of this work and in the emerging Interactive Digital Choreography alternative ways of moving bodies, new body shapes.

Comparing with interactive installations and digital art works, sound sculptures, immersive experiments, computer games and more recently Internet based forms of tele-presence, the Interactive Dance, in a more restricted survey of designated assisted art computers, can not vindicate to itself as long and heterogeneous history.

According to Gretchen Schiller, [3] since the beginning of the theatrical art, the artists have been expanding the concept of body through the materials and technologies, as a precedent for Interactive Art based on the movement. Sure there are many examples of dance choreography in which technologies were used, not just digital, transcending biological limitations of the body, such as the introduction of pointed shoes, in 1832, in the ballet *La Sylphide*. But, Loie Fuller was the first artist to stage the real technological breakthrough in the late nineteenth century when she began to make use of the lights not just to make the scene visible but also to create an atmosphere. She also used artifacts to extend and multiply her body image, or even transform it into animated shapes, and by doing so she brought into the world a new and revolutionary concept of dance.

After Fuller, the first experiments in the area of dance and technology are the films by Maya Deren (1940), and even before, studies on the chrono movement photography and cinema made by Muybridge, Marey and Mèliés, all of which may be considered in the historic route of digital animations systems called 'motion capture'. In addition, choreographers, researchers and teachers have used video, since this technology has been available, as an important tool to analyze documents or existing works.

In order to recognize the importance of women in Dance History and Technology we should not forget Thecla Schiphorst, [4] a graphic designer and dancer. She led a group of graphical researchers at the University of Simon Fraser (Canada), in the beginning of 1980. Schiphorst actually invented 'Lifeforms', a software that allows the creation of the choreography in a virtual platform where one can also watch

the choreography. It makes possible to the artist to see the movement from several points of view, a condition not available for real stage. Therefore, it was a woman who developed the software 'Lifeforms' but her name is not connected to the software she created. Instead, it became wordly famous through the name of a man, the north-american choreographer Merce Cunningham, who first worked with the 'Lifeforms'.

We cannot forget to register the contemporary choreographer Dawn Stoppiello, [5] one of the creator's of the software Isadora with Mark Coniglio of Troika Ranch Dance Theater, as another important modern matriarch in the history of dance and technology, specially her contribution to the development of a choreographic interactive language in dance performances. Stoppiello highlights the importance of interactive systems to meet these available to the largest number of artists interested in an increasingly simple and accessible to anyone with some training and familiarity with the computer.

We believe that in this new architecture for interactive dance, we have a new philosophical condition that enables us to be harmonic within the spatial context that we live, in wich we are immersed, and it is inseparable of our bodies. In short, a performative relational architecture that invites participation, and does not exclude the virtual architectures, besides it, includes the body in the experiment. We can not forget to mention the brazilian artist Lygia Clark that in the middle of 20th century and together with the Neo-concrete movement participants invited the body of the visitors to come inside of the objects and art installations, as a pre-historic stage of the Interactive art. For us is fundamental reveal this kind of no-mentioned history, the women contributions in the history of art and technology, in the history of dance and technology...

The dance creators have widely performed dance work in multimedia scenarios, sophisticated structured for consumption and aesthetic contemplation of the audience. Dance installations and online interactive dance, which invite user's participation are rare events. They form a new field of studies open to analysis and aesthetic evaluation of this new interface.

Each of these experiences and creations developed by choreographers with their software, offer different notions of what is the conception of dance, movement, body and the proposal of interactivity or even ideas of what is an interactive choreographic system.

The dance is seen in Brazil even as something to embellished and sculpt the female body, and not as a form of expressionist art, rebellious, much less as a way of developing the feminine discourse of her own body and authority, with few exceptions of recent contemporary dance productions. It is part of our school of Dance (UFBA) role to expand the notion of female corporeality building a more libertarian way, including tools for these bodies to be more independent, supplying ways to construct creative and technological autonomy in order to make a significant change in the former model and greatly strengthened in the countries of South America where most people think that technology is not a field of research for women.

How to change a trajectory of these female bodies used to attend the wishes of the choreographers who are mostly men? How to change the fate of little girls whose bodies are being forced into being more feminine and docile since childhood? How dance can change this reality and not just be another tool of body domestication?

This paper is rather an attempt to write the history of dance in interface with new technologies, highlighting those contributions often hidden in official discourse, which is the history of dance written by male.

There is still much to write, to fight, to do ... I write this paper for us all women...

THE FOOD SIDE OF SOUND AESTHETICS

LEANDRO PISANO

This paper describes some art examples related to sound/food topic starting from a scientific perspective and investigating the field bounded by performance art, sound art and research. Through comparing molecular gastronomy to digital music and analyzing the connection among sound and food as a way to re-design a rural territory, this paper outlines how the knowledge of food and sound can add important information in the 'tasting' process.

Our evaluation of food is related to a variety of contextual information perceived through the senses: the pleasure we get from eating is obviously influenced by the taste and the smell of food itself. Also, visual presentation and colour are important, as well as the feel of the food in the mouth, with its temperature and texture. The senses of taste and smell are so tightly combined in the evaluation of flavour that it is sometimes considered a form of synesthesia which is common to us all. Recently, researchers have been focused their attention to various cases of synesthesia. They are also analyzing if the perceptual experiences of syntesthetes are so very different from those of non-synesthetes.

Our senses undoubtedly are not isolated from each other. Indeed, living in a multi-sensory world, our brain constantly works combining data from different sensory modalities in order to make sense of our environment. Through reporting a number of cross-modal associations such as pitch and visual size, colours and tastes or brightness and the frequency of vibrotactile stimuli, some researchers have shown that these associations "are different from those present in syntesthetes in that they are bidirectional, and a stimulus presented in one sensory modality does not elicit a conscious experience in another modality. However, the existence of these cross-modal associations supports the hypothesis that synesthesia might originate in feedback connections from a point of convergence of the two sensory pathways." [1]

According to the latest research on the matter conducted by Sagiv & Ward (2006); Ward, Huckstep, & Tsakanikos (2006), cross-modal associations and synesthesia can be usefully compared in order to better understand both phenomena. Also, it has been shown that there are implicit associations between tastes and particular pitches: in particular, on the one hand sweet and sour tastes are associated with high-pitched notes, on the other hand umami and bitter tastes are preferentially matched to low-pitched notes.

As Charles Spence of Oxford University has stated, the perception of the crispness and staleness of potato chips can be affected by modifying the sounds produced during the biting action. Participants of the experiment were asked to bite into 180 crisps that had different freshness. The sound produced by the bite of each crisp was processed through electronic devices (microphone, computer, headphones) and edited in real time to evaluate the participants reaction. The results showed that crisps were rated 15% fresher and crisper if the crisp sound was played louder, or if just the high frequency components of the biting sound (above 2 KHz) were boosted.

Another experiment conducted by Spence was investigating the role of auditory cues in the perception of carbonation in beverages. The results showed that it's possible to modify the carbonation of a fizzy drink by changing its sound. As Lorimer Moseley writes, "In the future, we may be able to reduce the

amount of 'tooth-rotting' carbonic acid in fizzy drinks simply by changing the sound that the drink makes in the can. Prof Spence's research may also suggest novel interventions to bring back the enjoyment of food for the growing elderly population who have started to lose their sense of taste and smell since there is currently nothing we can do to bring back those senses once they have started to decline." [2]

Recently, an aesthetics experience called "Foodfrequency" and based on synesthetic and cross-modal research of Charles Spence, was presented by the chef Giulia Massimiliani, the dj Michael Byrne and the sound designers Marco Galardi and Sara Lenzi. During the "Foodfrequency" experience, participants were required to immerse themselves into the taste of Italian foodscape while listening via headphones to binaural immersive sounds of the origin of the ingredients alternating a multichannel soundscape without headphones. Through the sound experience, a connection was created with the tastes and flavours: the stories of the ingredient were narrated employing specific frequencies able to increase the food experience.

Charles Spence has also collaborated with Heston Blumenthal, English chef and owner of The Fat Duck, a world renowned restaurant in Bray, Berkshire, which researches the molecular compounds of dishes aiming at enabling a greater understanding of taste and flavour. Together, Spence and Blumenthal have experimented that it's possible to flip the flavour of bacon and egg ice cream by changing the background sound. The ice cream tastes more 'bacony' if who is tasting can hear the sound of bacon sizzling in a pan, while it tastes far more 'eggy' if some farmyard chickens acoustic samples are played as a background sound instead. Even seafood taste nicer when eaten while listening to the sounds of the seaside: The Fat Duck tasting menu has as one of the signature dishes a course named "The sound of the sea", a plate of seafood presented to diners together with a seaside soundtrack played through an iPod put into a seashell on the table.

Blumenthal is well known for being one of the chefs that in the past decade have inspired his work to methodology, philosophy and experimental approach belonging to the Molecular Gastronomy movement, in terms of experimenting the advances in biochemistry and soft-matter physics to analyse and comprehend culinary processes in an innovative way.

Although the term "molecular cuisine" cannot indicate a specific style of cooking, "as the chef labelled as 'molecular' have very different styles and the role of science in cooking is usually limited to the development of a new technique or a new recipe and there is very little 'science' in the final preparation of a dish," [3] it's interesting to notice that in the poster for the first "International Workshop on Molecular and Physical Gastronomy", held in Erice, Italy in 1992, specified that this meeting aimed to explore four points: "to what extent is the science underlying these [cooking] processes understood; whether the existing cooking methods could be improved by a better understanding of their scientific bases; whether new methods or ingredients could improve the quality of the end-products or lead to innovations; whether processes developed for food processing and large scale catering could be adapted to domestic or restaurant kitchens." [4] Two things need to be emphasised in this brief excerpt: on the one hand, the interactions between science and cooking, which at the beginning of the past decade led to the first collaborations between chefs and scientists: in France, chef Pierre Gagnaire teamed up with Hervé This; Heston Blumenthal with Peter Barham in England; in Spain, Andoni Luis Aduriz and later Dani Garcia with Raimundo Garcia del Moral, and Ferran Adrià with Pere Castells; on the other hand, an innovative research oriented to deconstruction (or reconstruction) of cooking in terms of the 'simple' chemistry and physics of the food.

In a way, these approaches can be compared with sonic technique of Granular Synthesis, in which sound samples are used often as grain contents. Through distributing grains in time and selecting parameters from the synthesis of each grain, the sonic quality of a granular texture can be obtained. Usually, the duration of grains is short and they are often distributed densely in time, so that the resultant sound can be perceived as a blend texture. "Granular Synthesis or Granulation is a flexible method for creating animated sonic textures. Sounds produced by granular synthesis have an organic quality sometimes reminiscent of sounds heard in nature: the sound of a babbling brook, or leaves rustling in a tree. Forms of granular processing involving sampled sound may be used to create time stretching, time freezing, time smearing, pitch shifting and pitch smearing effects. Perceptual continua for granular sounds include gritty/smooth and dense/sparse. The metaphor of sonic clouds has been used to describe sounds generated using Granular Synthesis. By varying synthesis parameters over time, gestures evocative of accumulation/dispersal, and condensation/evaporation may be created." [5] Granular Synthesis technique is the result of long-standing ideas about the nature of sound. In the second half of the last century, quantum physics have demonstrated that sound can be atomically reduced to physical particles. As Isac Beeckman has later explained, sound travels through the air as globule of sonic data.

Starting from 1950s until the last decade of XX century, some theorists or composers including Dennis Gabor, Iannis Xenakis, Curtis Roads and Barry Truax have contributed to evolve the particle theory of sound into a synthesis method whereby the natural sound particle is reproduced, being layered with other imitation particles, and the particle itself can be cloned or extracted through being processed with a similar method as the original, in order to create different sounds.

Definitely, Molecular Gastronomy and Granular Synthesis are featured by a common approach, not only through deconstructing and reconstructing molecular structures in order to act on the chemistry and physics of food/sound, but also creating through texturization process (in molecular cuisine with gelling agents, emulsifiers and thickeners; in granular synthesis with granular synthesisers/granulators) an evocative narration between micro and macro, liquid and solid, accumulation and dispersal, condensation and evaporation.

In the last years, linking sound and food is becoming an interesting research topic not only in the psychology of perception but also in new media art studies. The latest research is focusing not only, as we have seen before, on the key factors of hearing related to multi-sensory perception of food, but also on some vernacular expressions that are rising from a performance-oriented aesthetics research, analyzed through a multidisciplinary perspective.

Every recipe, as a list of operations to be executed in a time interval, could be considered as a contemporary full score that is at the same time well-defined and unpredictable in its sonic development. The sound and the taste of food can allow us to journey around the world by putting us in touch with different cultural traditions, localizing us in a precise context and by mixing cultural elements it can allow us to cover distances. If Heston Blumenthal once said that food is especially evocative in conjuring memories, we could extend the meaning of his words by saying: food and sound.

Among the most significant projects operating in the field bounded by performance art, sound art and aesthetics research, we can find The Vegetable Orchestra, a musical ensemble founded in Vienna in 1998 based on the concept of using fresh vegetables as source material for the creation of instruments (which are built for every rehearsal and concert from scratch), all sounds and all music. Dealing with expanding the borders of the notion of what is understood as music and by working with vegetables, the Vegetable Orchestra musicians also rethink the concept of sound as a permanent transformation from

food into an instrument and back to food again. During their performance, the instruments already fall apart. They change their consistence and loose water and shape. The sound elicited by the vegetables turns into smell and later into taste when the musicians enjoy with the audience their instruments at the end of the concert in form of soup.

One of the founding members of The Vegetable Orchestra, Ulrich Troyer, was invited for a residency project together with the cook Philipp Furtenbach and the musician Kassian Troyer during the 2006 edition of Interferenze new arts festival - a new media art event immersed in the forest of Mt. Partenio in the rural region of Irpinia, South of Italy. During the three days of the festival (the theme was "Naturalis Electronica"), the artists have condensated culinarily and sonically local food and sounds, through recording on location the soundscape of the site and combining acoustically this material with the sounds that emerged during the process of the preparation and condensation of the food. The process of the condensation has evolved slowly over the period of three days and in certain time slots during the festival it was possible for the audience to listen to and to degustate the condensation of the tastes and the sounds collected. A way to let the naturalistic and gastronomic identity of the place play together and to link together technology and tradition. What emerged from the project was not so much the result, but the process during which people were made aware of some ancient and very slow processes: visitors could come, taste and listen to the sound of the performance that was presented as a social sculpture, something focused on the value of the time, the importance of slowness, the sense of the place. [6]

This project was part of the Interferenze festival section called "Click'n'Food", which offers a panoramic of performances based on the relation among food, music and new media arts. Food represents one of the main theme of the festival, through a strong involvement of the typical food and wine of Irpinia, a tradition of high quality standards presented in an international context. The aim is to propose a path that, through projects based on evidence, creative intelligence and sensory experience, is designed to promote/foster a virtuous cycle where the quality of production and the consumption of food is inextricably bonded to sustainability, environmental quality and social relations. Through choosing "Rurality 2.0" as the theme for the 2010 edition of Interferenze festival, the curatorial board decided to offer a different perspective on rurality starting from the territory itself. Moreover, the location of the event, the Ducal Castle of the little village of Bisaccia, has become for some days a laboratory where a rural territory and its characteristics (identity, traditions, natural environment, landscapes, gourmet) lead to a more open expression where languages of aesthetics of new media become new forms of sharing. In this perspective, food was analyzed both from an economic and a cultural point of view. In the first taking into consideration detailed tracking of the supply chains, whereas on the latter it considers it as a trigger for sustainable local development and tourism, and as an important part of the 'Slow Life' philosophy.

This year, the Click'n'Food section was based on three residency projects that started some days before the festival: the first one, entitled "Noble Milk" has involved the sound designer Yasuhiro Morinaga and the video artist Antonello Carbone, that were asked to make a sound and visual reinterpretation of a field trip at high altitude on the Podolian pastures which the two artists had on the mountains of Irpinia in the days before the three days event. Podolian cattle originates directly from a big structure and long horny cow, called "Bos Primigenius", who is supposed to have been domesticated in the Middle East during the IV millennium BC and later coming from Ukraine to Italy during the barbarian invasions. Being a cattle who always walk along, Podolian needs big extension pastures: this requires to shepherds to practice the transhumance, that takes place in the Apennines mountains along the so-called 'tratturi', the wide grassy, stony or hard soil paths that have been originated from the passage or trampling of

herds. Nowadays, only 50.000 head of Podolian survive in Italy, due to its less adaptability to intensive stock-breeding. Although the milk produced by Podolian cattle is really not much and it is obtained only during limited periods in the year, but the quality is extraordinary: Podolian lives exclusively on pasture and never goes in the stall, also eating grass in areas of high mountains that are very clean and not contaminated and thus they can produce milk of high value both from a nutritional standpoint and as well from the point of view of transformation. Caciocavallo Podolico is a type of cheese made out of Podolian cattles' milk and is one of the finest food products of South of Italy, with its smell of milk, butter, fresh grass, smoked hay, stall, wet straw and with its taste sweet and sharp together in the most mature shapes. Yasuhiro Morinaga and Antonello Carbone performance at Interferenze festival took place in conjunction with a tasting of "Noble Milk", produced by cows fed by only forage and pasture without GMOs or silage.

The second Click'n'Food project was "Viand", asking Tana Sprague to analyze processes of production of Irpinia artisan cheese (mainly Caciocavallo). Reading through the filter media of aesthetic craftsmanship, sound, images of a secular tradition were merged together. "Viand" was presented at Interferenze 2010 in the form of a live performance articulated on the concept of multiple simultaneous perception. While the cheese maker Giovanni Di Roma was working to produce a Caciocavallo shape, Tana Sprague played background sound captured during her visit in the historical center of Calitri village at the Di Cecca & Di Roma's Caciocavallo cheese cave ("Grotte dei Formaggi"), which is a tuff cave where Caciocavallo shapes are aged. In such an ancient place, where formerly farmers lived together with pack animals, different devices have been recently installed in order to monitor the microclimate according different parameters (temperature, dampness, oxygen, carbon dioxide, ammonia, breeze speed) that let us know about maturing process.

In the last project "Foodjob: frequencies to dissolve under the tongue", the sound designer Enrico Ascoli and the local cook Pompeo Limongiello introduced the festival audience to the delicious tasting of sounds extrapolated and mixed live from the sizzle of codfish, a typical plate that has an important tradition in Irpinia, because it's one among the few types of fish which can be preserved for a quite long time. The performance was divided on different synaesthetic levels (taste, smell, touch, sight, hearing) based on a real time recording with panoramic and piezoelectric microphones of resonances captured during food preparation.

Finally, the artists involved in the Click'n'Food project are asked to live together for few days, in order to experience the preparation of a foreign experience that underline social and aesthetic aspect of it. They will eventually re-interpret processes acquired during this experience either in live and studios performances. The idea behind the Click'n'Food is to transform the elements that characterise the rural and peripheral region of Irpinia - where ancient roots of food culture are tightly intertwined with the territory and its local culture - in a fascinating mixture of imaginative narrative of tradition and pure aesthetic fun.

As Alessandro Ludovico writes, "How many other festival crews are able to organise such events overstimulating your senses, with free local fresh and delicious food (the caciocavalli cooking and tasting live session was a hit) coupled with new audio/visual interpretations? The intertwining of local specific culture and natural roots with the infinite narrative possibilities of electronic has been once again been exploited in this beautiful and peripheral land." [7]

VISUALIZING NEW MEDIA ART IN CENTRAL EASTERN EUROPE

Agnieszka Pokrywka

Numerous amounts of facts connected with new media art in the territory of Central Eastern Europe go unused because of the inability to see relationships between different kinds of information. To face this issue the idea of CEEMAC2000+ has emerged. This paper briefly discusses the basic terms needed to understand the new media art situation in the region as well as presenting the possibilities for CEEMAC2000+ development.

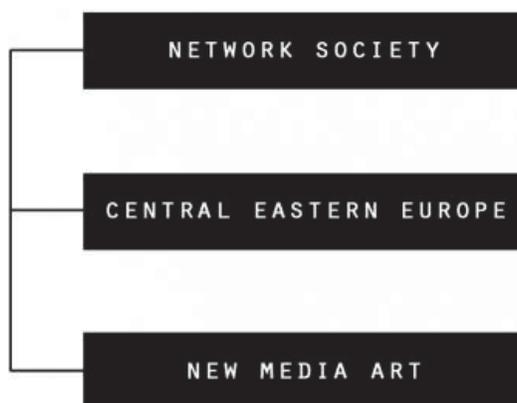

Fig. 1. Possible connections between three main terms described in section 2. Image by Agnieszka Pokrywka.

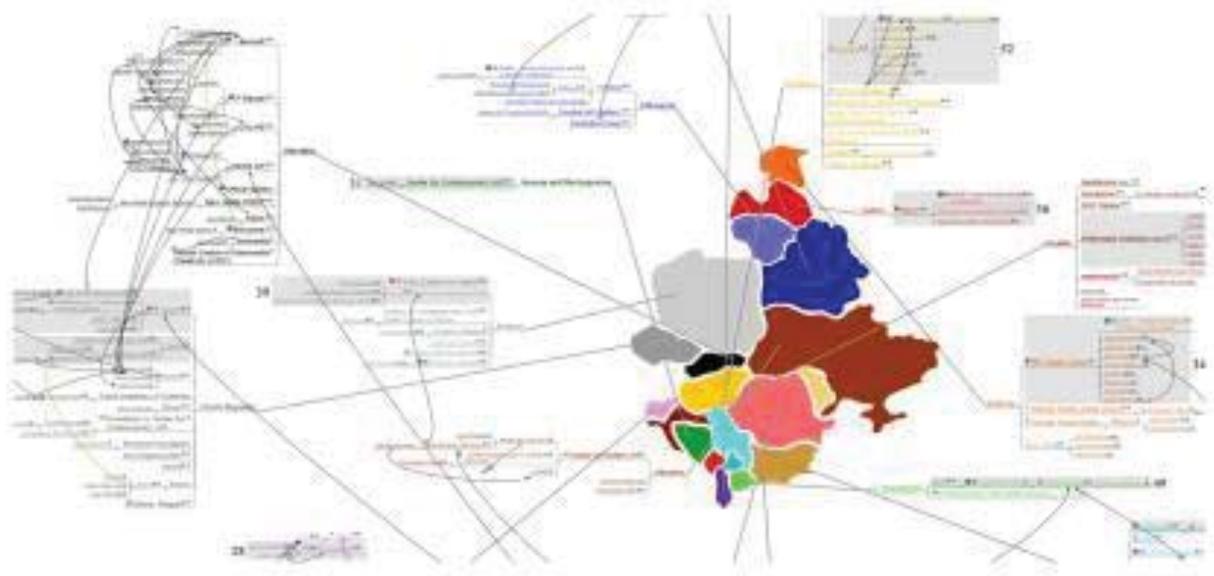

Fig. 2. Sketch of CEEMAC2000+. Image by Agnieszka Pokrywka.

1. Introduction

Central Eastern Europe (CEE) has for a long time been hidden behind the Iron Curtain in many aspects and is still an undiscovered hybrid built out of the past and present. Similarly, local new media art (NMA) is a tangle of historical and political dependencies mixed with current global influences (e.g. networked society, high technologies). In addition, the very dynamic specificity of this region blurs a wider view of CEE and NMA activities. As a result, considerable amounts of data and facts connected with this topic are unused simply because people cannot see any relation between them or visualize their quantities. The concept of CEEMAC2000+: Central East European Media Art Chart (2000-now) is intended to be a collaborative interactive map which could be able to present most of the networks, dependencies, connections between art centers, projects, and people which focus on local NMA development. CEEMAC2000+ aims to collect, share, and present large amounts of data in a non-linear, clear and visually attractive way, simply to create new artistic cartography.

The paper is structured in the following way. Section 2 briefly presents emerging terms such as CEE, network society, and NMA. Section 3 gives examples of how these terms can be merged. Section 4 focuses on data visualization and its use in the context of CEEMAC2000+.

2. New Europe, new society, new media

The first step of the CEEMAC2000+ project development is to explore stereotypical terms like CEE and NMA with a special focus on the history of CEE (Soviet times) and its current situation (network society, technological development).

2.1. CENTRAL EASTERN EUROPE

Norman Davies [4] states that borders between Western and Eastern Europe were changing a lot. However, the territory on which these bounds were moving did not belong to any of the aforementioned parts. Because of this, terms such as CEE have appeared. According to Piotr Piotrowski [10] Central Eastern Europe is a territory which from the late '40s up until 1989 was dominated by the Union of Soviet Socialist Republics (USSR). Nowadays, countries of this region (Albania, Belarus, Bosnia and Herzegovina, Bulgaria, Croatia, Czech Republic, Montenegro, Estonia, Hungary, Kosovo, Latvia, Lithuania, Macedonia, Moldova, Poland, Romania, Serbia, Slovakia, Slovenia, and Ukraine) are located between the so-called Western countries (Germany, Austria, Italy) and Russia.

2.2. NETWORK SOCIETY

According to Manuel Castells, [3] a network is a decentralized matrix of nodes through which communication can occur with a multidirectional freedom and which is not restricted by time or space. A common feature of all networks is the synchronization of each part and the simultaneous independence of every single node. These nodes have different levels of development and infrastructure which depends on the political and economic situation of the region in which they are located. The level of nodes development determines the whole network. Networks establish the new social order of current societies. This is caused by passing from the industrial age into the information age, and from energy to information. Castells sees the information technology revolution as one of the processes which leads to the production of new social morphology within a society.

2.3. NEW MEDIA ART

Marshall McLuhan [7] understands the medium as the message itself, which can create a new environment simply through its presence. To describe this idea he uses the metaphor of a light bulb which does not have any content but which certainly has a social effect and enables people to extend their daytime activities into the nighttime. Art creativity, which is based on media, can be explained as an art form which makes use of facilities such as electronic equipment, computing, and new communication technologies. As Louise Poissant [10] states, technology and its various processes are often used in experimental ways to produce different works of art. Additionally, Lev Manovich [8] explains that today's new media interpretation can be understood as the mix between older and newer cultural conventions for data representation, access, and manipulation. Here, the old data means a representation of visual reality and human experience, and often an understanding of culture. The new data is understood as numerical data.

3. New Europe + New Society + New Media

There is strong dependence and fusion between three terms mentioned in section 2. The most prominent of these terms are discussed below.

3.1. NETWORK SOCIETY IN CEE

Development of network society, where the key social structures and activities are organized around electronically processed information networks, is deeply connected with technological advancement which is lower in CEE (according to Digital Opportunity Index in Europe, 2006). Moreover, Manuel Castells [3] claims that it is not just technology which defines modern societies, but also cultural, economic, and political factors which make up the network society. Therefore, it is necessary to reflect on the network society in the context of its nodes' location which are in mutual relation.

3.2. NMA IN CEE

Net art, as one of the branches of NMA, has been strongly influenced by a context of cultural crisis in CEE at the beginning of the '90s. After experiencing separation and underground movements for some time, CEE net artists were able to notice that the Internet "a space where you can buy is a space where you can steal, but also where you can distribute." [5] Another example of dependency of new media artists on their location is the fact that tools which are needed for NMA creativity are mostly results of technological development, which is on a much higher level in so-called Western countries. It can mean that the specificity (or even existence) of NMA differs according to location, although recently these differences have seemed to become smaller.

3.3. NMA AND NETWORK SOCIETY

Uppgrowth of network society is influenced by technological advancement. This means that underdeveloped regions with limited access to new technologies are simultaneously on margins of networked society. As Manuel Castells states: "If you are not in this space of electronic communication, you do not

exist, in our society” [1]. Moreover, reduced access to technology both limits creative possibilities of new media artists and makes it more difficult to promote their works on a larger scale.

4. Data Visualization

The second step of CEEMAC2000+ project development is to thoroughly research data visualization. This can help to improve classification and understanding of large quantities of different data connected with NMA on the specific territory.

4.1. CEEMAC2000+ CONCEPT

CEEMAC2000+, networked graphs visualization, aims to record the relations between artists, curators, projects, events, and organizations which shape NMA in CEE. Time based dynamic topology of creative collaborations as well as patterns of contributors are planned to be freely-accessible and regularly updatable by the community of users. An interactive interface for navigating and exploring the network of artistic collaborations is embedded in the CEEMAC2000+ dataset and can bring benefits for both NMA creators (possibility of more aware collaboration) and its researchers (access to knowledge about particular nodes and their position within the larger network). CEEMAC2000+ wants to deliver new interfaces for flexible interaction with collected datasets and productive collaboration across borders.

4.2. CEEMAC2000+ REALIZATION

The main purpose of data visualization is to communicate information clearly and effectively by graphical means. Ideas can be communicated effectively thanks to a balance between aesthetics and intuitive functionality. Moreover, understanding leads to interacting which can help with the development of new media based art on this territory. According to Ben Fry [6] there are seven stages of data visualizing which can be found useful during CEEMAC2000+ implementation.

- Acquiring: obtaining the data.
- Parsing: providing some structure for the meaning of the data, and arranging the data into categories. Basic categories and subcategories are planned to be structured in the following way: people (artists, curators), events (projects, single events, cyclical events), organizations (media labs, centers, museums, galleries).
- Filtering: removing all but the data of interest. Network graphs can become confusing if there is a substantial growth in the amount of data. Because of this, CEEMAC2000+ omits events which took place before year 2000. Obviously only territory of CEE is in the scope of CEEMAC2000+ interest.
- Mining: applying methods from statistics or data mining as a way to discern patterns or placing the data in a mathematical context.
- Representing: choosing proper visual modes.
- Refining: improving the basic representation to make it clearer and more visually engaging.
- Interacting: adding methods to manipulate the data or to control what features are visible.

5. Summary

NMA in CEE is dynamic and changeable. This is why CEEMAC2000+ can be helpful in understanding the specificity and tendencies in the field. NMA creators, thanks to CEEMAC2000+, gain unique opportunities to have an overview of the movement of which they are a part. In the case of NMA researchers CEEMAC2000+ delivers new ways of documenting artistic activities, story-telling, and knowledge formation.

DIGITAL ART AND CULTURE AFTER INDUSTRY? – TOWARDS AESTHETIC BUSINESS STUDIES

Søren Pold & Christian Ulrik Andersen

The article discusses art's potential to critically probe new media economies and sometimes even develop new economies. With references to theoretical concepts from early marxist art theory it focuses on digital art, where the production, distribution, showing and selling has become part of the artistic work. The main example is *Electroboutique* (Chernyshev, Shulgin et al.), a series of works that address the current value of critical art.

Fig. 1. The exterior of the *Electroboutique* by Chernyshev & Shulgin, Trondheim, Norway, 2009.

Fig. 2. *Commercial Protest* (from *Electroboutique* by Chernyshev & Shulgin): A viewer sees her own portrait as a mosaic made out of transnational company logos.

Fig. 3. wowPod (from *Electroboutique* by Chernyshev & Shulgin): a huge distorted but still functioning iPod.

Digital Art and Culture After Industry? – Towards Aesthetic Business Studies

Who dominates in this country without morals, without faith, without any feeling; and from where do all feelings, all beliefs and all manners come, and where do they end? Gold and pleasure. Take these two words as guiding lights and travel through this great plaster cage, this beehive of black streams, and follow the serpents of this thought that agitates and lifts the work. You see. Examine first the world that has nothing. (Honoré de Balzac, *La Comédie humaine, Scènes de la vie parisienne*)

We live in a so-called 'new economy' and this is nothing new. New economies have emerged, boomed and crashed several times. Art and culture have played prominent roles in such new economies, from the 1880's panoramania to the various new media crazes during the last 30 years. Art often serves as the backdrop to champagne soirées and helps the nouveau riche establish themselves and gain some cultural capital during economic boom periods. In many instances this leads to a rather traditional, mainstream and sometimes even pre-modern view on aesthetics, far from the ruptures of contemporary art and aesthetics. A central example would be the concept of experience economy that Joseph Pine II and James H. Gilmore launched in the late 1990s. [1] If one looks at Pine and Gilmore's concept of aesthetics it borders on the escapist and is characterized by immersion and passive participation. Their principal guidelines are "Theme the experience", "Harmonize impressions with positive cues" and "Eliminate negative cues", and their primary examples are Disneyland, Las Vegas and the Hard Rock Café. [2]

However, art's most valuable contribution is perhaps not the icing on the cake or the aesthetic harmonizing of contradictions, but exactly the opposite: the ruptures, disruptions, clashes and breakdowns – all the ways that contemporary art explores things, situations and constellations that break apart, contain paradoxes or contradictions in relation to business. In many ways this seems to be the drive when "avant-garde becomes software," [3] net-art becomes web design or software art invades the app store. Instead of arguing that art might be a means to serve economic ends, we should ask whether the economy could potentially become artistic in some way.

Actually, we see traces of this already happening. When a cultural content industry, such as the music industry, is in crisis and its business model is deteriorating because of dwindling CD sales, competition from easy web-based distribution and copying, then both new and major acts bypass the industry by carrying out the marketing and distribution themselves, using the web and social networks. Instead of an industry of major record labels handling the relationship between artists and audiences, this becomes part of the artistic work defying industrial standards and forming less standardized and industrialized relations between artists and audiences. In fact, the business model, including how to finance, market, distribute and profit from the content, becomes part of the artwork and it becomes part of the artistic statement to question common models. This is of course helped by lowering production costs, easy networked distribution, new relations between artist/author and audience/consumers mediated by more flexible, dynamic or situational artworks. These new relations between artists and audiences are also indicated by diverse but related concepts such as “relational aesthetics,” [4] the “craft consumer,” [5] Free Software production and Free Culture including a culture of modification and remix. [6]

AESTHETIC BUSINESS STUDIES

Consequently, it becomes evident that art’s relation to the market and economy is part of the artistic development and innovation, but this also means that art becomes ‘about’ the economy in a more direct way. How should we interpret this, how do we learn from it, and how do we develop aesthetic business studies?

In order to look into this, we first need to introduce a few theoretical concepts from early marxist art theory, because here we can find positions that discuss how art can potentially play a critical, constructive, progressive, if not revolutionary, role. In the 1930s materialist art theoreticians such as Georg Lukács and Walter Benjamin were discussing how the change in the base, or “Unterbau”, of reproduction technologies affected the superstructure, or “Überbau”, of culture, economy and thinking, and how art could respond to this. A prime example is Georg Lukács’ reading of Honoré de Balzac’s *Illusions perdues*, which he sees as a novel about how literature becomes part of a capitalistic production process, and he discusses how this becomes a theme in terms of both form and content in the novel. The novel explores relations between developments in printing technology (personified by the printer and inventor David Séchard), book trade and the failure of romantic poetry (personified by the main character, the failed poet Lucien de Rubempré). As such, it is a novel about the commodification of literature and the capitalization of the mind (“Geist”). It is, however, not just a product of this, but rather a media-realistic, disillusioned although clear-sighted, literary exploration demonstrating relations between the base, the superstructure and literary strategies in this changing economy; and it does this through the literary form of the novel (e.g. the portrayal of the main characters, the use of melodrama, etc.). It is an example of a conscious exploration of a new discourse economy, exploring how material changes influence the formal conditions of the artwork. [7] The main character and poet, Lucien de Rubempré, becomes disillusioned, but the novel develops a view on the literary market and contemporary society through its development of an alternative formal, novelistic language.

With his concept of “Tendenz” (tendency) Benjamin also argues for a formal relationship between art and the production process in a way that might help elucidate how art can function as a probe for investigating change. Technological revolutions in media lead to fractures in artworks and art history, making the deep “Tendenz” visible. [8] In this way, the normally hidden, deeply layered fractures, constellations or contradictions become observable if probed by art. Furthermore, while constructing a marxist dialectic view on art history, Benjamin is clearly not interested in ‘politically correct’ literature and art:

...rather than asking, 'What is the attitude of a work *to* the relations of production of its time?' I would like to ask, 'What is its position *in* them?' This question directly concerns the function the work has within the literary relations of production of its time. It is concerned, in other words, directly with the literary *technique* of works. [9]

In continuation of these arguments by Lukács and Benjamin it is important that art is not created uncritically on the premises of media and economy but that it seeks a conscious, reflective and critical exploration, and this has of course become even more relevant with the rising importance of media. How the production process and market relations are positioned *in* the work is what to look for, rather than the work's attitude to the market and media. Contrary to the view on art and aesthetics promoted by Pine and Gilmore, we should look for art which focuses on the fractures that reveal deeper tendencies (Tendenz) when carrying out aesthetic business studies. Or, in other words, as suggested by the initial quotation from Balzac, follow the money; if not to collect it, then to see which new routes it takes and to observe the creatures and creations it passes by.

ELECTROBOUTIQUE

Let us start our aesthetic business studies and look briefly at some relevant art. Under the concepts "Media Art 2.0" and "Electroboutique" a group of artists, including Aristarkh Chernyshev and Alexei Shulgin, have made a series of artworks – each produced in a "limited number of copies (like Ferrari)" and sold "at affordable prices (like Sony)" – which they show and sell at galleries, festivals, museums and on-line, often installed in a shop-like environment. [10] The intention of the project is to create opportunities for new media art in galleries and museums, which have often neglected it because of technical difficulties and its immaterial character, making it difficult to exhibit and sell. Furthermore, many of the *Electroboutique* works also perform a humorous and poignant criticism of the (art) market and the relation between art and design.

One of these pieces, *Commercial Protest*, which is a flat screen TV equipped with a live camera contained in a shopping cart, showing the captured images – e.g. images of the viewer – as company logos, is introduced in this way:

It is difficult to protest these days against capitalism, especially if you are a member of capitalist society and enjoy all its benefits. Any convincing form of protest very soon gets appropriated by the system and starts being used for its sake: in politics, in advertisement, in design, etc. But we want to protest! – and offer the new, realistic form: *Commercial Protest*. We protest in the form of a critical but/and commercially suitable artwork. *Commercial Protest* reveals the essence of modern people; – it shows what we are all made of. A viewer sees her own portrait as a mosaics made out of transnational companies logos (variant: consumer goods). These images are globally recognizable and constitute the visual language of today. The supermarket cart that contains the TV set emphasizes the ugliness of the ultimately consumerist world. We protest against such state of things with this piece and set a fair price on it. [11]

It is obvious that this is a criticism of consumerism, which is paradoxically packaged as a nice, fairly-priced art object for galleries and collectors who can see themselves as live logo portraits. The irony is, of course, an integral part of the artwork, where the artist realizes that "criticism in art becomes an aesthetic category and eventually acquires itself the features of a consumer project," [12] and, as such, critical art becomes a brand in the art market. However, it is not only ironic but also a comment on a situa-

tion where software art is not accepted by the large institutions that still need objects, though the experimental and experiential dimensions of software have become an important part of the market, e.g. in smartphone app stores. Much commercial design is driven by innovations in art: however, artists often do not get a share of the revenue, especially in the copy-paste culture of new media. With this in mind, *Electroboutique* openly copies concepts from not only art history, including Russian Constructivism, and media art in the tradition of Nam June Paik or Jenny Holzer, but also from design icons, and relaunches them as new artworks – a good example being the huge distorted but still functioning iPod, *wowPod*, or the various distorted television remakes.

In short, we will point to the following tendencies guided by *Electroboutique*:

- The recuperation of critical art by design and the market, which *Electroboutique* answers by recuperating commercial aesthetics and rhetoric. This is done in a sincere, manifest and, to some extent, successful attempt to sell art and make a living, which is again creating some provocation in the new media art ghetto – e.g. when it was presented at the transmediale festival, Berlin, 2008. Recuperation is not new, neither in art nor design, but *Electroboutique* highlights its way of working by using it artistically and by recuperating design in media art for sale.
- Fractures between the immaterial and the object or between software and hardware in the art market and in the general economy – in this case, handled and highlighted by constructing object-based software art. This both mimics the more traditional contemporary art world alienated by new media art, such as net-art and software art, and alienates parts of the new media art scene; though more former net-artists are following the same route (cf. e.g. the attempt to enter new media art into the contemporary art scene of the Brussels art fair with the exhibition *Holy Fire*). [13] It is hardware-based art building on insights from software art, especially around the visual culture of interfaces, as stated in one of the manifestos: “We live in a world of visual interfaces. Televisions, print advertisements, politics, shop-windows, show-business, internet services, bank systems are primarily interfaces whose task is to shape the process of information transfer and the translation of ideas. Working with visual interfaces, we make them visible and tangible. We uncover the structures of today’s world.” [14] As such, *Electroboutique* smuggles software art into the art world disguised as artistic objects.

Of course many other examples could be made pointing towards these and more contemporary tendencies, but we hope you get the general idea: art has the potential to simultaneously question and develop the economy. There is a straight line from *wowPod* to iPad, and to the future of sculptured and visually attractive entertainment centres from Apple that will replace our TVs and hi-fis, or from *Commercial Protest* to the narcissistic self-promotion through one's iPhone and the many branded platforms on Web2.0 (just start watching how portraits mix with brands and logos on an average Facebook page...). As Piero Manzoni has already demonstrated with his *Merda d’Artista* in 1961, which was 30 cans of artist’s shit sold at the equivalent price of gold, the artist is the modern day alchemist making artificial gold. However, the smell of it, or its non-existent traditional use value, also casts a critical light on the virtual foundation of our money-based capitalistic economy. The main point is to focus on how art develops an artistic economy, and thereby reflects critically on the current economy while developing alternatives. As Shulgin himself puts it: “Contemporary art has got one more function. It finds out the possible borders of consuming.” [15]

THE BIG BANG OF ELECTRONIC ART: MERGING ABSTRACTION AND REPRESENTATION IN THE AGE OF DIGITAL IMAGING

ANAT POLLACK

In the society of the spectacle, the art of the mass media changes the Modern relationship between art and its audience. The art resides in the shaping of this unseen, diffuse spectatorship where the medium is the masses. Co-opted imagery in massmedia challenges the meaning of Abstraction & Representation. Artists who appropriate and decontextualize mass media images from consumptive value to the sublime is a form of utopian remediation.

"objet petit" #2 & #3. Diptych by Anat Pollack 2010

In the society of the spectacle, the art of the mass media changes the Modern relationship between art and its audience. The art resides in the shaping of this unseen, diffuse spectatorship where the medium is the masses. In mass media, context transmutes image from scopic to semiotic. The onslaught of media-images sublimates the image to the message, and renders it meaningless. In my work, I transmute semiotic to scopic.

In the "objet petit a" series, digitally modified images taken from television commercials shift the meaning of classical notions of Abstraction and Representation: the definitions of which are fungible within this context. Ads sell an abstraction: desire, fear, and or an idea, but not concrete matter. In the ads that I use, that which is represented, that is, the supporting signs and signifiers used to sell something are, at best, indirectly tied to the generic product at hand. They represent an idea, not the image represented, or even the product being sold. The connection is tied as a consequence of the context- nothing more.

This paper brings attention to my process of employing the appropriation, compression, and decontextualization of mass media imagery. The “objet petit a” series is comprised of digitally layered images that result in the erasure of an idea or commodity, taken out of context from what a TV viewing audience would consider normalized and concrete. I re-appropriate the signs and signifiers that were co-opted by advertisers to sell predictable and normalized commodities to an original state of sublime beauty.

Information systems within the context of capitalism, or, as Fredric Jameson calls “millionairism” has resulted in the normalization and commodification of all components of life. This has created great confusion regarding the very nature of our existence, destabilizing our perceptions of self, body, desire, and the social.

My artwork encourages interaction, offering the opportunity to engage thought, and a space for the individual to check and consider conditioned responses: like trauma. While automatic response and recognition is necessary for advanced thinking and rapid placement of information moment by moment, it also leads to automata – mindless, thoughtless behavior.

The ever-heightened velocity of images and ideas presented to us by mass media discourages analysis and promotes amnesia. The pleasure reflexes gleefully consume data like sugary soda pop. Memory doesn’t fail- it is merely unnecessary. I use signs outside of their trusted, codified systems, devoid of time, stripped of context, and re-present nothing but what is in the image. Frozen video stills of blurred landscapes forces at the very least interpretation and analysis, and at the most, pure experience. For some, to experience the Real is an experience of the sublime, through a momentary revelation of the immense power of the natural world or of the divine.

The blurred image is as desirable and untouchable as the ad. And yet, unlike advertising, which render us always incomplete, this traumatic experience of an encounter with the sublime distances the individual from their habituated modes of perception and response.

Using the familiar is meant to create an oscillation between the habitual and the existential. By using the language of a purely contemporary experience, in this case, exploited data that has been created for entertainment, for supporting market capitalism and fear in television ads, I hope to refer the audience back to their own experiences, to disrupt it, to “expose it; ... [that I] might reveal its automatism, even its autism” (Hal Foster, Return of the Real), and to offer a space for conscious action and choice. The experience of an encounter with beauty thus reveals the flattening of the human soul caused by exposure to mass media.

It is here I wish to create a space for the audience to come in contact with themselves, to feel themselves *experiencing* and room to reflect on their conditioned responses. Codified media images are sublimated to market whims, and create a self-loathing rooted in existential malaise. My work aims to strip the images of their consumptive value in order to offer new experiences that will contribute to new ways of seeing oneself. The resulting images epitomize the ineffable. An exquisite little object to own called experience. The “objet petit a” series is meant to be a return to the flesh.

As in JMW Turner’s famous painting *Snow Storm: Steam Boat off a Harbour’s Mouth, 1844* (coll: Tate Modern) where the only sign of Modernity is blurred and thus reveals the luminous brilliance of Nature, contemporary artists resist cultural amnesia and objectification through deliberate attempts to fight the

inversion of the human spirit. This process is one of utopian remediation towards memory instead of cultural amnesia and the objectification of the human to presence within the flesh. The space provided by these contemporary artworks redeem the soul and offer a transcendent experience of the sublime.

The collapse of time, space, and matter has been a desire of scientists and inventors for centuries. The time machine, transcendental mediation, and metaphysics, are all means of escaping the corporeal, the gravitational pull of the earth, and a freedom to exist in/on new planes of consciousness. In Buddhist practice, there is a constant move in the direction of experiencing the Real, to let go of earthly attachments, to let the pain in and to let it flow through, rather than being pushed out. For some, to experience the Real is an experience of the sublime, through a momentary revelation of the immense power of the natural world or of the divine. Through art, I seek to create a space for reflection, and an opportunity both for the audience to leave their bodies and to return changed. All images end at the flesh.

OPERA & THE CULT OF THE DJ

Justine Poplin

Video as projected light form can 'be' the Diva and take on its own physical presence. By using projection as a vehicle artists can initiate an alternate dialogue by creating a screen or screens that are physical in presence and through this physicality take on their own psychological space.

Fig. 1. Swimming in Foreign Places, 2000, Justine Poplin, Video Installation: custom made screen: cotton & pvc 1m x 1m Melbourne Australia © 2011 Justine Poplin.

Fig. 2. Habitat: Being the Alien, 2006, Justine Poplin, Video Installation: custom made screen: Perspex 152cm x 160cm x 2cm Beijing China © 2011 Justine Poplin.

The title of this paper 'Opera & the Cult of the DJ' was chosen to initiate a dialogue and to question the place of Opera in today's culture. The word opera in Latin simply means 'a work'. So, what is opera in the 21st century when opera is the amalgamation of all arts and supposedly a reflection of the times? It could be stated that the DJ or VJ for example is the contemporary New Media Diva. Michael Rush points out, that Bill Viola's video works are "explorations of light and form, matched by his interest in spiritual source material." [1] Video as projected light form can 'be' the Diva and take on its own physical presence if used in an extratraditional way. There are several Artists that will be discussed throughout this

paper that are making work that embodies a physicality in video projection, later I will discuss how video's physical presence became one of the driving forces of inquiry in my own work.

Artists working in the field of video art and new media have at times limited the creative outputs of their work exhibited in the gallery or public space by the notion of 'the screen'. The screen I am speaking of is generally rectangular in shape within the interface of a computer screen; or majestically projected onto flat, uninspiring surfaces boasting an aspect ratio of 4:3. There are however; other possibilities that artists have explored to create 'physicality' in projection, which extends preconceived notions of screen-based culture. Video projection can engage in creative strategies that push boundaries that extend the message of the medium. The patron saint of the digital age (Wolf, 1996) Marshall McLuhan theorised that media is an extension of the human body. "Just as clothing is an extension of the skin, the axe is an extension of the hand, and the car is an extension of the foot, the media are extensions of the mind." [2] An example of this is Australian artist Stelarc he has taken McLuhan's theory on literally in his own work where he digitally and/or mechanically extends the human body. We can re-contextualise 'the media' to assume the position of media/medium/new media/ video.

Video art and the New Media discipline have evolved significantly since Nam Jun Paik's shooting of the Papal visit to New York with a Sony Portapak in 1965. The seminal action of showing a slice of life in a public space by an artist created what we now call Video Art. "As collage technique replaced oil paint, so the cathode-ray tube will replace the canvas." [3] Paik became the first spokesman for video art and re-conceptualised the use of television as a medium by spiritualising and sculpting with the monitor. His work explored Fluxus ideas and the cinematic avant-garde that were new to the audience of the time. However, it wasn't until video projection was available and accessible to the artist, which in turn extended the possibilities of video to create a physical presence with video projection. "Video installation Artists are producing environments as itineraries, places to start thinking about art and life, rather than giving us maps that indicate where all the answers are." [4] Video installation can be an environment where the screen is in the centre of the room and the audience/viewer can freely roam and not have to view from a fixed position. Video installation with the use of projection creates a physical form in the exhibition space or installed environment. By using projection as a vehicle artists can initiate an alternate dialogue by creating a screen or screens that are physical in presence and through this physicality take on their own psychological space. This physical presence is illustrated in most of Tony Oursler's work and his video installation 'Influence Machine' 2006 is one example. Oursler projects video onto smoke from a smoke machine; the viewer can freely circumnavigate the work in its holographic-like, free-form state, illuminating video's post-human presence through projection. Oursler's "general theme was to mimetic technology, that is, technology that could be perceived as a direct extension of psychological states." [5] In video work such as this created from projecting pixels onto surfaces that are free-standing take video out of its rigid realm into the transcendental and phantasmagorical.

My interest in extending the possibilities of the projection screen began in my first year at university. At that time I was constructing screens or boxes that were freestanding and would sit or suspend. These were made from heavy gauge fishing line and cling film/wrap. I then projected onto and through these assemblages and the projected light would penetrate the installation and dimly leap onto the nearest wall. This was in 1991 when we were still using linear editing techniques and back projection screens were something quite magical. I then moved on to construct screens that still resembled a similar aspect ratio to a standard monitor but had them hanging or suspended in the gallery or public space. The audience again could choose a viewing point, as there weren't any seats or a bench to sit down on like what are offered in many galleries. I made several works from 1999 – 2006 that worked with these principles. It has taken many years to reach this point as the practice and passion of 'being' an artist has worn thin

on my post 30 approaching 40 year old bones. I trained as a singer from 12 – 22 years of age and was on the path to becoming an opera singer. However, when it was time to choose a university and to plan the next decade or so I chose art instead of music. I entered art school on my painting merit and embraced foundation year with the sheer choice of courses and experimented with photography, film, sound and video. I continued to pursue a connection and my Masters examined Multimedia and the Operatic Form. This led me to explore concepts of the voice and performance as realised through new technologies and cross-disciplinary means of presentation. Most of my work alludes to 'physicality' in projection, which extends preconceived notions of screen-based culture. A selection of work from this period will be discussed; the first two pieces Shower Songs and LaLaLa are traditional screen-based work. Swimming in Foreign Places, My Beautiful Laundrette, Vox Pop Environ and Habitat/Being the Alien are work that embody Opera and the Cult of the DJ and extend projection possibilities.

Futurist performance artist Marinetti showed his work 'Feet' in 1915. "To compress into a few minutes, into a few words and gestures, innumerable situations, sensibilities, ideas, sensations, facts and symbols." [6] Marinetti's work inspired the video installation 'Cropped'. Two custom made screens hang in the centre of the gallery space. Performers are shot from the waist down in bars, cafes and other public/private spaces. Cropped surveils the body language that takes place under the table. The placement of the projection screen was crucial to the work. A perspective that was normally reserved for under the table was now subverted to eye level. The screens were suspended in the centre of the space, so that projection could be seen from 360 degrees angles extending projection physicality in the space.

There are many artists that use song in their video work. Is this then the opera of our generation? When the word opera is used it often conjures up images of overtly theatrical stocky men and women gesticulating wildly and extending their voices with trained prowess. The use of voice and song as an art form has been used in the avant-garde performance work of Meredith Monk; John Cage, Laurie Anderson and most recently with Turner Prize recipient Susan Philipsz in 2010. These artists used techniques such as vocal extension, amplification and sound recording to create song and sound that crossed genre. This cross over became quite popular in Australia in the late 90's early 2000 with Artists such as Philip Brophy who in his sardonic satirical critique says, "An artist using a pop song in video art is like anyone either enrolling in a DJ course or wearing an iPod in public: Tragic." [7] Brophy's combination of buzz words; song, video, Dj and iPod all in one sentence have a resonance and cadence, as these elements are a prevalent reflection of art and culture today. Artists can work with these contemporary elements to transcend the 'tragic' to become more engaging by harnessing this cross-fertilisation of genres and extending projection possibilities.

American artist Robert Whitman's work 'Shower' 1964 is one of the earliest examples of the shift away from the cinematic experience of film and into projection possibilities in projection in installation. It was only after I made the work Shower Songs that I found Whitman's work. Shower Songs is an Audio Visual Environment that was created for 1st Floor Gallery in Fitzroy Melbourne, sound recording by Jennifer Sochackyj. In this work, video was projected onto the gallery wall. The position of the projection was on the inner corner of the wall wrapping the 90-degree angle. This work demystified the singer having them tangible and in a familiar space. The bathroom is usually a scene of intimacy and exposure of fragrant wet white lathers, of glass, ceramic, curtain, Hitchcock and song. The viewer is taken into a steamy, aural, visual environment where several people sing and bathe. Is it erotica, routine, love-scene, post-coital wash-down or recitative?

La la la is a screen-based work that explores voice and presentation. What is good pitch, tone and timbre when they can be digitally altered? What is a good voice? In an overexposed room flooded with light 9

performers sit in front of the camera one by one and repeat a sequence of 3 notes, that are played to them on an analogue Dictaphone, an aural examination of the recognition of time and pitch. A screen test. Each shot is a tightly framed over-exposed headshot. The close-up composition was used to create tension and to put the viewer in the place of the singer. Ultimately each singer's 3 notes la la la were edited audio visually constructing a composition that lasted for as long as the average pop song 2'33.

Swimming in Foreign Places was a site-specific work curated by Camilla Hannan and Nat Bates (Liquid Architecture). There were two sound artists Hannan and Bates and two video artists Van Sowervine and myself. The couplings were to perform a live surround sound mix to pre-recorded video. At the time I was reading a lot about Bauhaus and Dada performance and came across László Moholy-Nagy "Nothing stands in the way of making use of complex APPARATUS such as film, automobile, elevator, airplane, and other machinery, as well as optical instruments reflecting equipment, and so on. It is time to produce a kind of stage activity which will no longer permit the masses to be silent spectators, which will not only excite them inwardly but will let them take hold and participate—actually allow them to fuse with the action on the stage at the peak of cathartic ecstasy." [8] Laszlo inspired the work I created for Swimming in Foreign Places. I custom-made a circular screen that hung in a tree like a strange fruit. The projection started with a gradual ripening of colours from green to earthy browns this being used as a metaphor for a fruit ripening on a tree. After several deaths of fruit a tightly cropped singer's headshot appeared. The head (the artist) was hanging in the tree singing a song without melody. This was layered with sur/subtitles taking us into a place not many of us have been. The lyrics projected were from Abel Meeropol's 1936 poem, which 3 years later became the well-known blues ballad 'Strange Fruit' sung by Billie Holiday.

My Beautiful Laundrette performance installation is a site-specific work. Behind the doors of an after hours laundrette in Melbourne, a piano introduction to a Mozart aria from The Marriage of Figaro is audible. Two whopping speakers spill the melody into the street. The audience assemble outside (the doors are locked). Inside the dimly lit laundrette the diva is plugging in pieces of equipment preparing for the performance. The aria she will sing is from an opera where the character has lost a pin; she has misplaced her stereo jack, and ponders whether the mix is good. She is standing behind a dj booth wearing a powdered wig, mixing herself into the soundtrack with karaoke sur-titles on the custom made screen above her head. The aria ends and other lyrics appear on the screen, another Mozart aria 'Batti Batti', then Kate Bush's 'Hounds of Love', followed by Britney Spears' 'Hit me Baby', all songs are about love, all sung by women and all transcending time when seen in text form. Voltaire once said: "anything too stupid to be said is sung". Seeing the lyrics displayed in this form whether classical or pop amalgamated the texts and made one no higher art form than the other, a blend of genres transcending time.

Vox Pop Environ is another site-specific work that was made for a Melbourne pub's disco room. Manzoni, the artist who is most favourably know for selling shit, sold his bodies of air (artists breath) in the 1960's for 3000 lire and he wasn't a singer. 'Vox Pop Environ' digitally replicates and projects the gestures we use when we sing; the eyes, the mouth, the hands, all vehicles for external physical expression, the mechanisms > the trachea the vocal chords the diaphragm hidden. Multiple projections of operatic gestures were projected onto balloons (the screens) atop slim wooden rods with a plaster base. The singer is now a balloon (a diaphragm) on a stick inflated by artists breath, performing to a pre-recorded soundtrack composed from voice samples, extending vocal performance and projecting a physical performative presence.

I further examined extratraditional notions of screen culture and performative presence in 'Habitat/Being the Alien' exploring notions of cultural identity. If you are Australian what exactly does that mean and

what image do you portray to other cultures? In China if you introduce yourself as Australian, most Chinese immediately say “kangaroo” – big rat. The work is a dialogue between the lyric and the visual. I created masks around the standard format of the rectangular workspace in preparation for the projection. The first mask was surrounding the kangaroo this mask was black as black does not project. This gives the screen the illusion of a freestanding kangaroo and in turn initiates a physical presence in the gallery space. The second mask was inside the kangaroos face; here I inserted moving footage of a face speaking, uttering and gesticulating with various marsupialistic facial expressions. The soundtrack created was ambient Australian bush sounds mixed with utterances in Chinese and Mandarin about wanting, waiting, and missing someone or something that give a sense of disconnection, longing and isolation. Songs and the land make us; we are defined by our culture and history. There is a sense of displacement and familiarity, knowledge of being an alien that creates a dialogue between the lyric and the visual.

The work I have discussed was made over a very intense period of time; I was investigating multi media and the operatic form examining the place ‘opera’ in 20th –Century Art. The work created mostly explored the use of voice in contemporary art whilst simultaneously extending methods of presentation to reach a broader audience. The hybridisation of new media is synonymous with the way we live our lives. There will always be a place for Opera in its historic sense for dramatic deaths and augmented librettos with 15 year-old Japanese girls falling in love with polygamous American sailors. There are also many contemporary Opera companies that John Jenkins and Rainer Linz discussed in their book ‘Arias – Recent Australian Music Theatre’ 1997 that employ video and new media in their work. However, these still mostly follow pre-existing conventions of opera, such as having Directors, Designers and Composers. To reiterate, the word opera simply means a ‘work’ and in the current climate of cross fertilisation of art forms this leaves a lot of room for artists to interpret and create works that reflect this. “The concept of the moving, temporal image is a key modality through which artists have articulated new strategies and forms of image making; to understand them, we need to fashion historiographic models and theoretical interpretations that locate the moving image as central in our visual culture.” [9] Opera and the cult of the dj is a reflection of the times and work that uses technological devices that extend the possibilities of video installation and its physical and psychological presence in a space. This in turn creates a shift in the expectations of the viewer and preconceived ideas about opera/multi -media and modes of presentation in the 21st-century.

NEW MEDIA CONTEMPORARY INFORMATION PARADIGMS: THE REORDERED MEMORY ON FILE ARCHIVE STRUCTURES

GABRIELA PREVIDELLO ORTH

New Media contemporary information paradigms, leads the discussions that increase the perceptions about digital art Memory content, highlighting the FILE Archive, under the perspective of intelligent systems. With an Information Science theoretical approach, the study will raise perspectives in using these expert structures, considering the recent goals to develop a new FILE Archive environment.

"(...) the technologic machines of information and communication operate in the core of human subjectivity, not only within their memories and intelligence, but also within their sensibility, affections and unconscious ghosts." [1]

From Information Science point of view, this study on the cultural practices of the contemporaneity incorporates the fluidity of its research object: The electronic and digital art archives, considering here the postmodernity highlights in the information, its constitutions of mediation and access.

In this sense, the digital art information environment works its discursive communities, providing directions for its flow. This flow, which inserts its agents in culture and technology issues mediated by the information device, enables the reflection of these agents in its emancipation instruments. The parameters for this reflection are not individual, but subjective.

Art document intermingles with artwork and artwork becomes a means of art documentation. As well as the contemporary dialogue between men and machine, the memory diachronies rebound on individual and social spheres. The contemporaneity reorders the memory. In this logic, the memory is the future and its present comprises all the histories, emphasizing the randomness of the information flow in contrast with its stable linearity. The examination of this flow through digital Documentation asserts the development of the field through signification routes and provides its contextualization in the technological tools that are absorbed by it.

The digital art archive is manifested as the nature of its works. It has a memory importance, a variety of concepts and a heterogeneity in its exhibition standards which asks for an intelligent system model that operates with several types of media and languages. In today's archives and Documentation centers of digital electronic art, spaces still not interoperable are being designed and constituted individually as assorted pieces waiting for their whole. This isolated information requires a complex reading of its connections.

Distinguishing the potentiality of the artistic objects, while producing new artworks and communicational flows, is a way of Documentation. The potential elucidates the appropriation of memory and stimulates the generation of knowledge.

In the analysis of electronic and digital art information environments, the complexity concept is present in their Documentation structures. Parameters for information treatment and flow will be addressed under the FILE Festival perspective and will be contextualized in the digital culture memory axle.

The Festival gathers works of aesthetic expression that are diversified in the following areas: artificial life, hypertext, computer animation, games, interactive movies, digital panoramas (360° photos), electronic and robotic art installations, in interactive and immersive rooms. FILE Festival also organizes in each edition the FILE Symposium with several theorists and artists of digital culture presenting their researches and since its last edition, with the creation of the FILE PRIX LUX, it awards best Brazilian and international works registered in electronic and digital art.

The digital electronic art works documentation initiative has been happening since the first event edition (2000) and prioritizes access to the works presented in the Festival through its website. [2] In this web interface, the Festival promotes a fruition environment in digital culture through the navigation in two main search environments: an Archive database and the Hotsites produced annually for each edition of the Festival.

In this environment, connections are available for the conceptual overview of the work, artist's biography, photo and for the work itself, if it is online. This is the interface available for the user through web environment or in digital art centers such as the Oi Futuro space in the city of Rio de Janeiro. [3]

FILE does not own art works of these databases and in order to be exhibited again they have to go through a new negotiation process with their copyright holders, whom may be artists, collectors or research institutions. For an immersion through the categories of works and their contexts, the interfaces available are the websites of the previous editions.

From the documental point of view and for the access of the Festival professionals to the information available, data is organized as a reflection of the exhibitions. The FILE Archive mission is guided under the perspective of audience and works presentation. Information is inserted in system through registration forms that are filled by the authors. In these forms, there is the first (conceptual and technical) information about the work and also about the artist. These forms are a guide during the whole process of trusteeship and organization of the Festival. It is signed by the work copyright holder, allowing the work exhibition in both the festival and the web interface. With the exception of installations, the works are sent through FTP and start to integrate the Festival off-line collection.

From the choice of works until the exhibition opening, the works selected are indexed in a second database that feeds the website, the main interface of audience and researchers with Festival content. Attached to information of databases, Festival documentation consists on technical detailing information sent by the artists that is complemented by email exchanging among artists and Festival coordination crew. The assembling guides, concerning digital art works Documentation, are the core of the work preservation, once they will allow the works to be emulated or recreated in current exhibition conditions in the future, keeping the original conceptual and technical parameters of the works.

On Documentation context, photos and videos registering Festival editions are also filed, as well as catalogs and media clippings of the event, with part of equipment and all production and management documentation of the event filed separately. The theoretical contextualization that inserts the works in digital scope culture occurs through the documentation of articles presented at the Festival Symposium and articles electronically published in the event magazine, as well as books that are launched in each edition of the Festival.

It is important to highlight that FILE Archive has been structured on the Festival exhibitions.

Considering the described informational environment of FILE Festival, the information flow privileges the complex body of works annually registered, comprising the inherent heterogeneity of culture production in the electronic and digital information environment. The documents were selected in an organic and decentralized way, keeping above all, the relation between information, and perception of their totality.

In this moment, FILE Archive is an instrument for curators and also promotes FILE Festival. It also intends to serve as a research information instrument and for that it is focused on its own collection through documentation practicing view, prioritizing cultural contextualization and dynamically monitoring the information flow, which nowadays has intense circulation.

This documentation apparatus tends to become more dynamic and instable. Working with its structures and boundaries demands some contact with the perennial and some dexterity by dealing with the rhizomatic axle that is present in these environments.

These environments are made of interactivity, constant updating of their means and replica potentials of their content, being presented as possible transition systems for the future intelligent network machines. This is not about eliminating all linear documentation, but to build one more layer of informational axle, stimulating the production of memory instruments and interacting in the knowledge sphere provided by Art.

File Archive environment will focus on information transmission and in the potentiality of its objects, absorbing a nonlinear indexation, thus allowing users to become independent on their readings and representations of subjectivity through an interactive relation with the environment. For non-expert interlocutors, the intelligent automation of information flow offers a large amount of entries and possibilities of appropriation of its content.

In general, FILE Archive works nowadays on some guidelines such as: physical treatment of the artistic object and its digital support, expansion of information organizational tools (Topic Maps, Ontology, Controlled Vocabulary), creation of a free codes repository available by artists and creators, linking of theoretical production to scientific universities databases and documentation focused on the production of new works and research. Besides these practices for archive content treatment and diffusion, there is the intention to expand communication channels of FILE Archive with other institutions, professionals, artists and all community involved with the digital electronic art and its developments.

Digital Art archives may also serve as a parameter to other archive areas, from the research in their objects to the analysis of their structures, which present a complex and multimedia nature. "The art humanizes the machine" [4] and in the case of the digital art informational environments such as the FILE Archive the relations among document, technology, art and their interlocutors are considered an important axle to electronic arts Memory, stimulating the creation of new works and keeping the interaction of their actors dynamic and creative.

CITYSCAPES – EXPLORING THE SPIRIT OF URBAN IDENTITY

Francesco Proto & Richard Vickers

Turned into a mere relic of the modernization process, contemporary cities have stopped providing answers for the people they were meant to serve. Static, often imposing and inscrutable, the city is now a sphinx whose silence costs lives in terms of the psychic response to their complexity and size; most poignantly, to the isolation they engender.

INVISIBLE CITIES: TOWARDS AN ARCHAEOLOGY OF PRESENT TIMES

1.0 THE NARRATIVE

Turned into a mere relic of the modernization process, contemporary cities have stopped providing answers for the people they were meant to serve. Static, often imposing and inscrutable, the city is now a sphinx whose silence costs lives in terms of the psychic response to their complexity and size; most poignantly, to the isolation they engender. In light of this, the research is framed to uncover how people extract meaning from the built environment and how, in an act of reciprocity, the latter underpins their identity. The goal is to develop an original analysis of the role of contemporary cities in shaping and supporting western lifestyles through the representation of architecture in cinema. A series of short films will constitute the final research output. Shot in significant metropolitan areas around the world, they will illustrate the theoretical background underpinning the whole endeavour in critical theory, visual culture, cultural studies & psychoanalysis.

The starting point of the whole project is Italian writer Italo Calvino's *Invisible Cities*, a novel intended as a collection of descriptions of the cities that the Venetian explorer Marco Polo visits within Kublai Khan's vast empire. Based on the original *The travels of Marco Polo* – travel diaries recording Polo's journeys through the 13th-century Mongol Empire – Calvino's book is a reflection on contemporary cities as these become invisible to the eye: buried as they are under an interior, "represented" city, the real city disappears beneath a thick layer of fantasy. Such is the case for Venice, for instance, its Disneyfication rendering the true Venice virtually invisible. Hence, "[t]he only way to get at Venice is to use the water – its refractions, reflections, the play of light and shadow, and to re-create Venice where it has always been strongest – in the imagination" (Winterson : 2001).

It is thus clear that, to Calvino, stories, memories and signs always replace, cover and erase the real city, thus turning the latter into "the trace or track" of something "which is forever absent" (Spivak, in Welsh : 2007).

There are in fact:

the city of dreams;
 the city of memory;
 the city of desire;
 the city of history;
 the city of the future;
 the city of destiny;
 the city of simulacra

the city of spectacle;
 the city of consumption, etc

In other words, everything but the city as such. Invisible cities are in this respect nothing but a catalogue of obstacles impeding an “unmediated” perception of the world – as Calvino would put it – each city existing as a metaphor for the “invisibility” of experience. As a result, not only is the experience of the real city impossible; but also dependent on a form of obliteration, of erasure, of ‘re-writing’ of the ‘real experience’ that, at the end of the day, is all encoded in this very act of re-writing as such.

2.0 METHODOLOGY

Bearing in mind that for French psychoanalyst Jaques Lacan re-writing is a therapeutic mechanism meant to aid recovery from a trauma, it appears that the city has become a massive exemplar of automatic writing, its inability to provide answers being a symptom of that disconnection from reality now days affecting us all. The question thus arises of how to decode it; ie, of how the city is perceived by the observer, which is overall our ultimate aim. The answer is twofold: on the one hand, we have summoned up a model derived from psychoanalysis, ie Sigmund Freud’s “interpretation of dreams”; on the other, the cinematic act as an irreplaceable means for doing this.

2.1 THE FREUDIAN MODEL

With regard to the dream-work, Freud used to distinguish between a dream’s manifest and latent contents. That is, given a sequence of images as the apparent narrative of a dream (manifest content), it is possible to draw out of it a number of interpretations (latent content). Manifest and latent contents from a dream therefore overlap, although both are perceived as if part of a continuum; and indeed they are, if it was not for the fact that, according to the psychoanalytical model, a dream is subject to interpretation so as is a film. There is, in this regard, a parallel we can draw between a dream and movie, this parallel being based on the narrative (sequence of images) both are based on. To interpret a dream means in fact to change its structure exactly as to interpret movie means to change its montage. And it is starting from this assumption that a movie can represent the way our mind works.

On the other hand, the dream-work is never objective; to the degree that the meaning of an image is always affected/distorted by subjective drives and individual history. Hence, the very idea subtending out project: to employ a film to mirror the way in which a dream-work works, under condition that the stimuli aroused by a city are such as to put us in a dream-like state.

This position is particularly clear in *Inception*, a film in which not only the dream-work is represented as a kind of onion-layered nucleus (beyond the latent content of a dream, another follows, and another,

and another); but such layers – or “levels” (as they are called in the film) are always ‘infested’ by the dreamers’ “projections”, i.e. elements belonging to the dreamer’s personal history that “colour” the dream-work with ever different meanings.

Once we have established that what we perceive of a city is never a mere sequence of images, but rather the multi-layered overlapping of personal projections, the problem arises of how to “decode” the manifest experiencing of a city. To us, cinema holds the key. Not only because a film is, by its very nature, the thing most similar to a dream; but also because its particular structure, based mostly on montage and film editing, allows for the simultaneous presence of different layers of images, thus resembling as closely as possible the interpretation the research proposes of the city as multilayered field of experience.

2.2 THE CINEMATIC TRANSCRIPTION (OR RE-WRITING)

Sergei Eisenstein, the Russian filmmaker famous for his pioneering film theory, wrote that film montage always represents a moment of “explosion” of the image; ie, the very moment where a film sequence (as a situation, or event), is decomposed into juxtaposed images to reveal the inner meaning of the sequence. It is easy here to draw a parallel with Freud’s dream-work and, from the latter, with the model of perception we have indicated for the city: the cinematic montage can operate definitively as a metaphor to illustrate/articulate the multi-layered compression of meanings. However, what we are interested in is exactly this idea of the image’s explosion; ie, the possibility of making the latent content of the dream-work available in the form of a hypertext. Hence the use of use of cinema as a means to accomplish this task.

3.0 HOW THE SUBJECT EXPERIENCES A CITY

The methodology rests on the subject-ification of the camera’s eye. The short films, in other words, will make objective a condition of generalized unease that is difficult to grasp unless visualized. The films seek to act as an imaginary “screening” in the mind of the beholder, thus “visualizing” the mental and emotional associations that the experiencing of contemporary cities arouses. It is in this respect that the cinematic short will act as a hypertext able to make visible an invisible process: the overlapping between visual stimuli and the random/rational associations the former provoke in the mind of the observer. The final aim would be to provide an account of the impact that the contemporary city has on its user/consumer, thus highlighting the broadest range of experiences possible.

BEYOND PARADIGMATIC SHIFT: MAPPING CULTURE AND SOCIETY OF DIGITAL AGE

Mikhail Pushkin

Global paradigmatic shift is triggered by advances in digital and network technologies. New, Inherited, enhanced, and discarded features of this paradigm are presented. Digital Age is synthetic with features from modernism, postmodernism and earlier paradigms. The argument is supported by referencing modern, postmodern and contemporary theoreticians. Neo-Marxist criticisms are used to identify the distinctive points of the new paradigm.

Introduction

Making sense of one's own contemporary society and history, forming a coherent holistic image is a complex task, as one is situated "inside the box" of their timeframe, blurring the boundaries of perception and evaluation. Present day individual, however, is faced with an even more difficult condition: that of living at an early stage of an entirely new paradigm. Neither modern, nor anymore postmodern, yet bearing traits of both, our age is evasive of classification and not apparently structured and definable. Precluding the possible postmodern criticism of the need for 'constraining' definition and structuring, one may only point out that we have to establish a system of shared signs and signifiers embedded into a coherent framework to rationalize the principles determining global and local processes surrounding us, even if not fully accurate or all-encompassing. While no theory will likely ever be the universal solution, only through understanding and by now at large reconstruction of post-postmodern reality, will we be able to make conscious effective improvements and take full advantage of social, scientific, cultural and technological progress.

Multiple New Paradigms

Having the advantage of retrospective makes it easier to structure and comprehend previous paradigms, making them appear more coherent, holistic and identifiable, though not in simplistic static homogeneous terms. Like the Renaissance or Enlightenment, present Age already has several names, signifying its core elements, its catalysts: 'Digital' Age, 'Information' Age, 'Computer' Age or 'Network' Age. This equivocal yet evident paradigmatic shift leads academicians to generate possible interpretative post-postmodern frameworks coming with a range of neologisms like "digimodernism, pseudomodernism" (Kirby), "remodernism" (Childish & Thomson), "altermodernism" (Bourriaud), "third wave" (Toffler), "neomodernism" (Heller, Grauer), "new sincerity" (Epstein), "posthumanism/transhumanism" (More), "hypermodernity/supermodernity" (Eagleton, Augé). Combination of the stronger sides of these hypotheses is one of the better strategies to develop a solid holistic paradigmatic framework. For instance, Kirby's digimodernism (skeptical, media, culture and society-focused) combined with the third wave of Toffler (holistic, positivist, economics-focused idealistic image of further individualized 'hypercapitalism') [1] can be used in mutually supplementary fashion.

Digimodernism has decisively displaced postmodernism to establish itself as the twenty-first century's new cultural paradigm. It owes its emergence and preeminence to the computerization of text, which yields a new form of textuality characterized (...) by onwardness, haphazardness, evanescence, and

anonymous, social and multiple authorship. These in turn become the hallmarks of a group of texts in new and established modes, which also manifest the digimodernist traits of infantilism, earnestness, endlessness, and apparent reality. [2]

“In a Third Wave economy, the central resource – a single word broadly encompassing data, information, images, symbols, culture, ideology, and values – is actionable knowledge.” [3] He further emphasizes extreme decentralization penetrating the production and consumption, national identity, state structure, government and even family institute.

Most theoreticians place ‘the digital’ and ‘information’ at the centre of the new paradigm readily offering a set of very clear fulcrums for such shift: Internet, Digital Technologies and Networks. Those are the necessary information transport and dissemination arteries, that basis allowing for a formation of new society with distinct features reflected in global and local scale of existence involving politics, commerce, society and culture. Furthermore, the paradigmatic formation follows in part ancient principles, representing a synthetic (‘organic’ as opposed to postmodern ‘eclectic’) Hegelian evolutionary process merging modern and postmodern principles and ideas into a complex multisystem structure. Such synthesis is conceding with postmodern critical skeptical stance on monolithic structuralism, yet upholding the principle of multiple resilient potent empowered structures, essentially a pluralized networked version of modern structure concept. As the new paradigm changes the very basics of reality evaluation, its nature appears paradoxical from earlier perspectives with such features as globalization and interconnectedness as well as nearly unlimited information access coexisting with unprecedented growth of distinct subcultures and glocal communities, interpersonal alienation (computer mediated contacts as opposed to direct ones) as well as grotesque phenomenon of global misinformation and possible reduction of factual knowledge through information overload, manipulation and falsification (e.g. Wikipedia and Wikileaks): virtual becomes more wholesome, detailed, real.

Reversing Baudrillard’s negative concept of simulacra, digital virtual reality instead becomes a transformative, revolutionary expansion and informative improvement on predigital reality. Internet is therefore providing space for dialogue and a platform for creating new products, which are real, yet within a different framework not necessarily requiring a physical equivalent (in the same way a novel is real, but more complex), illustrating the key element of the new paradigm: shift of value system from physical to virtual, digital, the information pure.

Tetrad and Digital Age

To identify and understand the new paradigm one needs to establish the points of its distinction, to which adapted McLuhan’s tetrad concept, originally dealing with medium evolution, but transformed into paradigmatic evolution model might be of aid.

NEW TRAITS

Global interconnected digitized society completely redefined concepts of time, space and identity (an impact comparable to that of the public railroad transportation emergence for Industrial Revolution), forming multiple new value systems within localized social clusters embedded in globalized conglomerate system. Neither local isolated ‘tribes’, nor global monolithic culture and ideology. Memory becomes externalized, brain and sensory apparatus extended. [4]

Valid illustrations include international academic, research, religious or subcultural communities. They are interconnected through Internet (or only existing online), sharing own value systems, interests, goals. Sometimes such are largely coinciding with mainstream, other times are unorthodox, even radical. The members do not anymore need to be connected geographically or even know each other's real identity. The communication process (not limited to interaction, results in joint creation of virtual or even physical products and services) may follow an arbitrarily established strict or flexible timeline or even be of a sporadic nature (online forum posts). Specific examples would be gamers waking up in the middle of the night to participate in an on-line in-game event, possibly taking place during the day in another time zone. A now frequent situation that can be compared to a late night business phone call to another continent, or a heart surgery procedure broadcast online for education and consulting purposes, or an entirely online accredited international university e-education with over 5000 degrees, all of which illustrate the creation of new value systems and social structures based on virtual space and identity, often more important to their participants than daily routine and in more radical cases basic human health needs.

INHERITED & IMPROVED TRAITS

From media and entertainment domination to the virtual reality hegemony.

With the shift towards virtual space, media reality, as the main venue of infotainment, socialization and trade, World Wide Web becomes a place of value creation, not anymore wholly based on physical reality external to it, not unlike contemporary stock market. This gradually takes global economic structures further beyond post-industrial into global e-commerce with individuals and small companies offering local customized goods and services worldwide [5], using Internet as the marketing platform. As the digital requires constant research and innovation, quaternary sector becomes more important and profitable with originally smaller software and hardware innovators becoming world-leading multinational corporations such as Google, Microsoft, Facebook and Apple, all forerunners of the Digital Age, skipping the relatively brief postmodernity in their successful development.

Now digital, media goes in what might be described as 'overdrive', shifting the already immersive experience of a movie theatre into portable entertainment-information-communication products (tablets, smartphones, netbooks), while interactive, personalized, customized, individualized and yet pseudonymous news reporters and bloggers are reaching the audience through even more information channels, creating a complete complex system of (not infrequently misguiding, purposefully and otherwise) worldview. Such worldview becomes a custom-tailored massive digital prism, through which reality is perceived and evaluated. One may argue both for and against this prism, as it might either enhance one's knowledge and understanding, or completely distort it. [6]

Extreme customization of supply and demand becomes one of vital features of contemporary information supply and mining with the suppliers struggling to tailor user profiles to serve the kind of information (in simplest cases – direct advertisement) that will influence the audience. The "prosumers," [7] however, gain the power of manually or semi-automatically filtering out the bulk of undesirable information, thus both shaping the supply and demand structure of virtual reality and its products, and gaining a new kind of control over information production, intake and processing. This situation reestablishes the core principles of reality perception and validation arguably reducing influence of sensationalism and misinformation, as contemporary generation is born into reality (not just online) which is by de-

fault virtual, constructed, relative, fostering and necessitating development of new information selection, filtering, processing and validation mechanisms. Such environment fosters exploration and renegotiation of values, facilitating new forms of creativity and consciousness, shaped by the logic of code, as well as confusion inherited from postmodern explosion of nihilism.

DISCARDED TRAITS

Materiality (of information, identity, wealth, property and entertainment), privacy (contrary to the mainstream media-suggested spreading of democracy), copyright & ownership (due to combination of pseudonymity, remote ownership, digitization and piracy) and memorization.

Material reality has most certainly not vanished and global wars for territory and resources are raging at the same or even greater pace (coexisting struggling global corporate capitalism paradigm described by Toffler as the second wave). For the general globalized population, unless personally affected, they directly translate into local oil prices, (un)available vacation spots. What Digital Age adds or rather alters is the virtual presence and virtual active participation: immersive Video Games “recreating” the hot-spot events, blogging and live feed from the hot spot: real and fake so indistinguishable that one cannot anymore take either for reality. In effect, the actions, events in themselves become important beyond earlier more simplistic good versus bad framework. The audience becomes aware of watching or participating in a created narrative, globally pragmatic, rather than locally dramatic, being forced to ask *cui prodest?* On a less political note, one could consider timeless classics of multiplayer ego shooters, Counter Strike, where terrorists and police forces are equally popular with players, stripped of their ideological connotation.

Furthermore, digitized and digital video, audio and textual products can now be created, copied, advertised and distributed manually at virtually no cost via Internet, placing both publishing and distribution houses in a dubious position of trying to survive in a new pervasive global socio-economic system, which has little real need for their dated services. Most obvious examples point to McLuhan’s medium tetrad concept with paper-print and DVDs slowly, but surly becoming obsolete, with portable e-tablets (consider clay ‘tablets’ as ironic reference to antiquity), smartphones and e-readers gradually making books and printouts a thing of the past. Paper-based text is surviving on conservative medium loyalty, multitude of existing production hardware and routines, as well as through the pressure (economic, political, legal and otherwise) of gigantic non- and semi-digital manufacture, publishing and distribution giants inherited from the pre-digital age.

The very notions of materiality and the means of production are taken to such a different level, that one may consider material world to be chasing after the virtual one, curiously reviving and reworking antique debate on mimesis. An ironic illustration is digital cartoons, films or video games, where living actors and scenery are being digitized into animated characters, enhanced and then inhabiting the new better-than-real diegesis of “Avatar” or “L.A. Noire”. One can look further into the way contemporary blockbuster movies are structured and presented, as if molded after videogames, which follow almost immediately.

Remote and outsource jobs number increased dramatically both in material and digital/virtual sector (software, finances, IT support). The former, child of industrial age, is becoming ever more mechanized and self-sustaining via digital control systems or imported, while the latter, the new, is locationless in its

core principle: information (now in itself a product) is likely located on a server in some specific geolocation, however, its identical up-to-date copy is likely backed up elsewhere or even distributed among multiple computers world-wide.

Pseudonymity becomes the new identity with customizable optional gender, race, class, location and visual representation (avatar). On a more global level, potent hacktivist groups are formed. The “Anonymous” can serve as the most notorious example: ambivalent global hackers-activists group, networked, decentralized, yet organized (multiple cells and individuals worldwide), effective (able to bring down websites for government security companies, i.e. HBGary Federal and global credit card systems, i.e. Visa and MasterCard), with own moral principles system, e-anarchic.

Lastly, Internet has already integrated itself into the core processes of human mental activity beyond simplifying communication, but acting as a gigantic “External hard drive for the brain”. [8]

RETURNING TRAITS

Dialectical, ‘textoral’ in its earlier phase culture of “global village” becoming “global theatre,” [9] community, holistic thinking, social responsibility, layman philosophizing.

While Internet communication seems to alienate people from their direct physical environment, it at the same time facilitates and intensifies communication with a much wider audience based on interest, rather than random chance. Multiple blogs, forums, social networks demonstrate rebirth of, now online, communities, which become centers of heated debates on global and local issues, suggesting growing popularization of dialectics. Members of online communities are responsible to abide by the rules set out in the said communities, fostering a new sense of social responsibility, usually without harsh consequences, providing a safer environment for personal growth (or leading to infantilization in young adults due to lack of harsh consequences). At an early stage of digimodernism the main bulk of communication is textual, though the nature of communication could be seen as a multivocal enhanced oral one, only written down. There is, however, no reason to assume that with further advance in audio-video digitization technologies text will not once again give in to the oral and visual communication.

Even the family institute goes through a similar transformation with a curious rebirth of arranged marriage institute moving from the hands of the parents into organized or automated virtual matching sites and portals offering any kind of partnership pairing.

Marxist Angles

Marxist and Neo-Marxists are notable for the skeptical angle frequently downplaying the role and magnitude of change in their eternal struggle with capitalism. Gramsci further develops Marx’s theory of hegemony, presenting his contemporary world order and class-culture-production system as an adapting self-sustaining flexible construct, maintaining that social order by making subjugated classes internalize value system of the ruling elite. His theory permits one to see a contrast of new hegemony (paradigm) of networked digital reality: classless virtual space; own tastes (signified by Bourdieu), values and morals system, not involving monetary capital, but information cultural capital; the “new intellectuals” born out of Internet “habitus”, establishing themselves through skills, abilities and effort inside the virtual environment; use of hi-tech equipment previously reserved to and class-sustaining for bourgeoisie.

Chomsky criticizes contemporary media with introduction of five filters: ownership, funding, sourcing, flak, ideology. Schiller and Lovink further criticize online polyphony of active audience as confusing cacophony of confused impotent audience. Online blogging journalism, social networks coordinated events, political and cultural discussions on forums, hacktivism, pseudonymity and the new values system negate the issues of ownership (free), funding (inexpensive or free), sourcing (more diverse), flak (pseudonym as security, safety in numbers), ideology attack (online always contained multiple ideologies flourishing through lack of censorship and higher anonymity).

Conclusion

The article in a very compressed form confirms and describes the paradigmatic shift, highlighting its advantages, providing references to its conglomerate synthetic nature including beneficial elements of earlier paradigms dating as far back as antiquity, yet forming its own distinct and unique system of values, classes and tastes, made possible with the aid of digital technology and networking. Although this paradigm is growing in parallel with global corporate capitalist framework, it bears sufficient distinct features to be seen as a complete society-based hegemonic structure undermining the evolving invasive preceding global hegemony through passive rejection and active substitution of its incentives and values, while making use of its technological advances.

DATA TRASH

Melinda Rackham

Data Trash traces the texture and tactility of HTML - looking critically at the evolution of the online interface and its appropriation back into object based artefact; clarifying the pivotal place of the network in our cultural realm.

Stella Brennan, Tuesday, 3 July 2001, 10:38am, 2001-2002, detail- cotton on canvas.

Does HTML leave a trace of tactility and texture?

Net art first appeared in a geeky corner, a few degrees removed from existing curatorial and museum practices. When Marc Andresson's *Netscape Web Browser* was introduced in 1994, it opened up new frontier of immersive, intimate public space unmediated by the art museum. On the net artists believed that they could work without context or censorship, retaining control of their content while constantly connected to a global community.

The net seemed like an intimate affair - a rich tapestry of connections. There was an element of forging a new craft. Stella Brennan has captured needlepoint, created in cotton on canvas, [Figure1] the Apple Macintosh operating system at the turn of the twenty first century – a view we no longer see as the landscape has radically changed. The approximately one meter square *Tuesday, 3 July 2001, 10:38am*, simply depicts a screenshot of Brennan's desktop, encapsulating an era.

The best networked art often relied on non-standard software and hardware, on glitches and on happy accidents to function. It was built with dynamism, rather than preservation in mind. We've already lost many fleeting works from the early experimental days of Internet art through corruption and mutation. Net art archives usually retain a minority of works – ones which are straightforward to conserve because of their common and stable formats, or their ability to be easily migrated. . With the certainty of either going out with a crash or slowly fading away, online art becomes data trash.

Ironically material culture responded to these issues with a mutant field of migratory practice with artists producing static artefacts from the ephemeral net.art works almost as soon as the works appeared! The wonderfully whimsical *Introduction to net.art (1994-1999)* a manifesto formulated by Natalie Bookchin (USA) & Alexie Shulgin (USSR), carved on six marble tablets by Blank & Jeron (Germany). The representation is derived from the Blank & Jerons work *Dump your Trash (1998)*, where a software agent recycles existing web pages into new pages. Pages filed at this site stay stored even after the original has been long lost or shut down. The texts carved in stone secure their presence in the physical world while simultaneously subverting the ephemeral - an ironic commentary on the way we deal with data in the information society.

The memorial concept is taken further with Nick Crowe's *The New Medium (1999)* – fifteen glass panels hand-engraved with internet memorial pages that had been submitted to a web site called Virtual Heaven. First shown at the long defunct Lux Gallery, London in January 2000, *The New Medium* examined different forms of internet use including the iconography of personal homepages and the growing use of cyberspace as a spiritual medium. The fragile works glow faintly in the gallery full of sentiment and touching naïvety.

Investigating the point where the mind starts to confuse what is reality and what is illusion, Jan Robert Leegte focuses on the physical experience of the internet. His *Scrollbars (2005)* installation isolates elements of the Windows interface, which are projected onto various structures. As an artist he moved from being internet-based, to creating physical installations to develop a more meditative relationship between the audience and the work. Pixel depth is perhaps too superficial?

Carving in stone or painting on canvas secures a presence in the physical space of an object-driven art-market. The Google browser is surely the most painted, sketched, photographed and built interface artefacts, with Japanese artist collective Exenemo's 3.5x 2.5 m *Google (2004)* painting being one outstanding example. It is of course owned by the Google collection.

The *Rhizome* screenshot, drawn on paper with pencil and gouache (2000) by Russian Masha Moriskina, was as well, immediately bought by art portal Rhizome. Moriskina continued to create highly desirable web page renders – important historical documents which reminding us of the long forgotten stories of Internet art victories such as that of the eToys/Etoy wars! [1]

It was never an easy fit as existing art forms such as drawing, photography, poetry, video, animation and radio moved to the net, adopting the unique aesthetic of chunky pixelated low res images, low bit sound, and the now vaguely recalled rhythm of slowly downloaded net-art. Networked art challenged but never usurped the well-established commodity value of the discrete art object and the primacy of authorship.

In 2003 Thomson and Craighead created the *dot-store* - an e-shop environment which delivered a series of artworks both on and offline. This included “a beautifully crafted set of four tea towels sporting a series of authentic search engine results returned to a user when the criteria, 'Please Help Me', 'Is Anybody there?', 'Please listen to me' and, 'Can you hear me?' were entered into the search field, while using Google in Netscape 4.7 on Mac OS 9.2 or Netscape 6 on Windows 98.” [2]

The printed textiles, embroidery, drawings, engraving, sculptures, paintings, machinima and etchings have a ready-made future while the ephemeral coded works they are derived from do not. To break

the glass, to trash the art, to rip the fabric is to scatter the bleached bones of HTML – the skeletal remains of the lively richness that once connected people across networks.

As we speed into that future, there is a certainty of corruption and mutation and decay. Online work becomes disposable data trash, environmental and cultural wreckage, littering the web with dysfunctional and lost artworks. But remember today's data trash will resurface, be revalued and recycled in a not too distant future.

TERRA VIRTUALIS: THEY ARE REALITY

Melinda Rackham

Terra Virtualis, an exhibition of virtual art curated by the Australian Centre for Virtual Art (ACVA). It positions Australia as apart from, yet intimately cojoined to the rest of the world and is critically driven by the relationship of physical location in virtuality and augmented reality, to the expanded concept of site-specificity.

Rainbow X Apocalypse, Video Installation, 2011, Anita Fontaine & Geoffrey Lillemon.

They are reality. (1)

A red taxi snakes through an unexpected patch of greenery, swimming against the mid-evening, mid-level traffic up to the sanctuary of the Church of All Saints. My semi-permeable skin registers the shifting levels of moisture in the air ascending the Peak, as warm and cool oceanic currents. Satellite imagery and subjective back-stories of my destination scroll across the luminous tablet purring, fan humming and drive vibrating almost imperceptibly, on my lap. Outside black soil erupts from between concrete superstructures, teasing my nostrils with tropical fecundity as we pass.

Taxi morphs into a Fastback of undulating pattern; golden palm trees sway in the virtual breeze. You and I embrace like we have never before - exposed to our core. Anita Fontaine & Geoffrey Lillemon's *Rainbow X Apocalypse*, engulfs me. Beautifully. If 2012 is the final year of human existence I want to live fast and die young so my soul can be avatar for ever after in the *Metaverse*. [2]

Architectural scale generates minuteness and magnificence. Insignificant human creatures scurry below acres of highway flyovers, disappearing into transit tubes beneath ground. Life is cheap below the million dollar video displays atop the scraper canopy. Silhouetted by flickering neon, each tower competes for air space, every level presents a bigger, brighter, blinding surface animation. Our 21st century mega polis recalls with fond nostalgia its *Blade Runner* past while seductive faceting distracts our attention from the present realities of our *Diamond Age*. [3]

The ecosystem of *The Institute For Advanced Augmentiform Development and Release* exists in parallel to several others. It nurtures live interactions and data exchange. Virtual and the augmented realities dynamically link as Andrew Burrell & Warren Armstrong make us, the inhabitants of one world, responsible for the survival of the others.

*She must suspect.
She senses her being.
Her memory is situated.*

Women will notice it first. The virtual, like Irigaray's autoerotic female genitalia, [4] is not one. We touch ourselves constantly and the virtual is simultaneous. *Écriture féminine* [5] is perhaps the best way to speak on the subject of the virtual, for here knowledge and memory are foreigners. To know the virtual we must be immersed – to give ourselves over to being within soft, wet, hard space. Our pliable data bodies surrender to touch and meld with the unknown. We must have courage to play in the *Terra Virtualis* - territories of unknowingness. For it is when we try to feel, to know, to recall, to rename, to remember, that we do not experience what is. [6]

Meandering is that. Aroha Groves takes us seemingly randomly through her worlds. Her grand design, a connected thread of ideas, emotions, environs, and forms of consciousness will touch us, touch ourselves, and touch our soul.

Contemporary art will be virtual, or it will not be. [7]

The virtual is beyond photographic. The image is not recalled; rather we re-sense the intensities of experience. Virtuality, vitality, virtuosity is embedded and distributed like a rash of scarlett fever under my skin. There is no event, no horizon to orient my self against. [8] Trueness or falseness is not in contention here. Software parses the next scenic level. We do not lack vision in our rendered reality; we do not need optical illusion – frustration only arises from lack of control. The cartographies of the virtual have moved off the grid and beyond of the Street that runs the entire 216 km circumference of the perfectly spherical *Metaverse*.

The urban space shifts. *Neomaflux*. Augmented Reality resets perception. Troy Innocent and Indae Hwang construct urban space as it should be – a network of connected relationships. AR markers generate spatial digital language and abstract mindspace as mediated ISEA delegates consider the collective intelligence of the space itself.

Our experience of the intensity of virtual art is a moment of pure potential pleasure. This interstitial art, the art that happens when we are not quiet conscious, generates a moment of ambiguity and a mo-

ment of discomfort. But we must resist reaching backwards - grappling for the ease and comfort of recall. This moment of being in the new territories is a moment of reality, of being within the flow of our bodily sensation. Let go and drift curiously into *Terra Virtualis*- into the crevice of unknowing.

We are not one - we are virtuality.

Melinda Rackham, Hong Kong and Istanbul, September 2011.

TRACING THE CITY: EXPLORING THE PRIVATE EXPERIENCE OF PUBLIC ART THROUGH ART AND ANTHROPOLOGY

Martha Radice, Kim Morgan & Solomon Nagler

What happens when the private experience of art is disrupted or reframed by the chance encounters and events of urban public life? Conversely, what happens when modes of production of art are opened up for the public to intervene in artistic creation? We draw on Lefebvre's sociospatial theories to present the framework for our interdisciplinary research-creation project, and use it to interpret an art installation on a public city bus route.

Whatever its form and setting, contemporary art tends to privilege a one-on-one relation between the viewer and the art. In the gallery, people encounter artworks within the bubble of their own personal space. In the cinema, they watch films ensconced in the dark, in a comfortable chair. People feel emotional reactions to art within their own bodies and express them to only a small circle of companions. Their experience of art takes place in a social context, but is typically privately contained. This paper – written by an urban anthropologist, a multi-media installation artist and a film-maker, respectively – presents the premises of an interdisciplinary research-creation project that questions this one-to-one relationship. We posit that the public space of the city can challenge – and indeed can creatively be made to intervene in – the private space of engagement with art. We ask, what happens when the private experience of art is disrupted, unsettled or reframed by the chance encounters and events of urban public life and space? Conversely, what happens when modes of production of art are opened up so that the public can intervene in processes of creation?

In our individual practice, we are each driven by a concern to investigate the sociospatial dialectic: the idea that the organization of society is necessarily expressed in and constituted by the organization of

space, such that transformations in the one effect change in the other. Our collaborative project explores the urban sociospatial dialectic through a combination of creative processes in the visual and media arts, principally film and site-specific installations, and empirical qualitative research in the social sciences. [1]

The sociospatial dialectic and new media art

We draw on Henri Lefebvre's conceptual triad of the social production of space to theorize our work. [2] *Spatial practice*, or *perceived* space, consists of people's perceptions of society through space that arise in their ordinary activities and routines, and the material settings and objects involved in these – the commute to work and the bus, the weekend movie and the cinema, grocery shopping and the supermarket. *Representational space* is the realm of symbols and images, also called *lived* space, because spatial symbols can be 'lived,' non-verbal, ineffable or clandestine rather than explicitly articulated. Here, space can be invented and imagined, and critiques of society and culture are possible. The visual, rhetorical and performing artists, the chefs and the artisans, the urban shamans, priests and diviners work in this kind of space, adumbrating the meanings that attach us to cities. In contrast, *representations of space* are consciously codified by those who have the power to shape and define society, such as urban planners, technocrats and scientists. Also called *conceived* space, this is the view from above; representations of space contribute the kind of knowledge that makes the city immediately or potentially knowable, productive and 'useful'. For instance, an anthropologist makes representations of space in order to understand it more accurately. Of course, anthropological research also involves observing and invoking spatialized routines and symbols. Each kind of space cannot be fully understood in isolation from the others, but together they refract the nebulous concept of 'space' in useful ways.

The sociospatial dialectic has evolved in ways that Lefebvre could not have foreseen, thanks to new information and communications technologies (ICTs) that collapse time and distance: cellphones, GPS, social media, GIS, and Web 2.0 protocols, which allow us to track and construct complex representations of geographical and social data. This spread of virtual space and its intersection with the material alter our conceptions of what 'space' really is, challenging "three deeply embedded assumptions [...]. First, that space is three-dimensional and shared between actors. Second, space is either solid or void. And third, you can only be in one place at one time." [3]

The collapse of the virtual and the material also blurs boundaries between public space and private space. In urban anthropology, the distinction between public and private space is not based on ownership or function, but accessibility and visibility. Space is public when it brings strangers from all walks of life into view of and into contact with each other, as individuals and groups. [4] Private space, in contrast, implies invisibility and interaction with an already known, even intimate circle of friends and family. New ICTs bring the private realm into public space – as you hold an intimate telephone conversation with your sibling on the bus – and the public sphere into private space – as you post comments on a newspaper website in the comfort of your living room. What results is an expanded idea of presence in space, and a sort of open border between intangible and material space.

This open border has been extensively explored by artists. However, we have two criticisms of many of the artworks that we have reviewed so far. Firstly, artists often incorporate locative media technology in ways that shrink public space into the personal world of the cellphone or computer screen. For instance, dialling a number posted on a wall or even, thanks to GPS, simply approaching a site with a cellphone can deliver a lyrical representation of that location through the phone to the listener, but it's for that

listener's ears and eyes only. Our second criticism relates to public participation. The new layers of the sociospatial dialectic seem to have integrated seamlessly into our everyday lives, and yet this very seamlessness conceals the authoritarian nature of the media. GPS and GIS were developed primarily as tools for making representations of space (conceived space), to better survey, know and control territories and their inhabitants. Interactive art projects – representational spaces – make earnest attempts to use ICTs to place authorship in the hands of the users. However, they often retain a hierarchical relationship between the artists and the public participants by selecting and therefore censoring interactive content according to non-transparent protocols, even when there is no technical requirement to do so.

Time Transit

In contrast, we aim to build on work that uses ICTs to broadcast over a wide swathe of the city and to decentralize authorship. One such example is co-author Morgan's *Time Transit*, a temporary mobile art installation that combined art, engineering, public transit and digital media in order to explore the impact of ubiquitous technology on our daily lives, and its potential to generate both interconnection and alienation in urban public space. [5] The installation site was the City of Regina Transit bus route #4 (Walsh Acres/University), a route which, significantly, traverses neighbourhoods that vary greatly in class and culture, from the university through to the impoverished north central ('the hood') to wealthy new suburbs. The installation had three principal interactive public components: an operating city bus; six major bus stops along the route equipped with cameras that constantly filmed them; and a website with text messaging and email (<http://timetransit.com/>).

The bus was fitted with a GPS system, four flat-screen monitors, a computer and a wireless network connection. Two monitors were mounted near the front of the bus and two near the middle of the bus. Each set of two monitors displayed the same content, which meant all the riders could experience the installation more or less equally as they rode the bus (Figure 1). The monitors displayed images captured from the cameras that were focused on the six major bus stops along route #4. The right-hand screens showed real-time images of the next filmed bus stop along the route (i.e. where the bus was going). The left-hand monitors displayed images from the most recent major bus stop, and these images were translucent stills layered on top of each other, to represent the cumulative, collective memory of gestures and activities from where the bus had been. The passengers were thus able to view what had happened at the last stop and what was happening at the next stop on the screens. The website (Figure 2) showed the real-time location of the bus as well as film from the bus stop cameras. More importantly, it allowed users to communicate with the bus by typing a text message into a sidebar textbox, which would be displayed as scrolling text on the monitors of the bus. The message could either be displayed in real time or be dropped at a particular zone along the route, in which case it would show as soon as the bus reached that location. In addition, people could send messages to the bus via cellphone text message or email. A display hierarchy was set up to give these latter messages priority over ones from the website.

Time Transit made plain the ways in which ICTs fold time and space in on each other. Firstly, the installation existed in virtual and real space simultaneously. People could experience it by riding the bus, by appearing at the bus stops that were monitored by cameras or by browsing the website where they could either view or interact with the installation in real time. Secondly, *Time Transit* cumulated past, present and future: riders could see where they had been and where they were going. They could watch themselves board the bus or see friends waiting for them at their destination. Thirdly, *Time Transit* played

with conditions of surveillance and anonymity. Using their private cellphones, riders could send messages to unknown others that would be displayed publicly on the bus screens. Website users submitted messages to known passengers: “Larry bring home milk.” The installation thus permitted privacy and even intimacy to dwell in the very public space of the bus. As one art critic wrote, “[*Time Transit*] not only prompts up to consider the city and its citizens but prompts subtle shifts in our understanding of how we occupy and experience the city and how we shape it – and it shapes us.” [6]

While *Time Transit* pointed to the ubiquity of surveillance technology and its effect on our perceptions of private and public space,[7] it also challenged our paranoia about such issues. Here the users controlled the content and data collected by the equipment. They could appear before, perform for or hide from the cameras, remotely operate them, watch and be seen on-screen. They could publish their own stories and read those of other passengers – tales of their day or experiences of the public transportation system, shout-outs to friends or cheers for local sports teams. Regulars posted stories as serials, in daily instalments. Poetry often scrolled across the bus monitor screens... and so did profanity. Following a series of pointed insults, and at the request of the bus company, the project engineers added filters to censor profanities, but riders could also put their considerable creativity to work in finding ways to curse without using the forbidden words, circumventing authorial regulations. In this way, members of the public contributed to the installation not only by precipitating the activity (using the bus, viewing the screens), but also by creating its content.

To use Lefebvre’s terms, *Time Transit* used conceived space – surveillance technologies and new ICTs – to create a lived space – an art installation – by means of perceived space – the everyday bus journey. The representational space had the unexpected side-effect of creating a new practical representation of space, in that this interdisciplinary artistic inquiry led the project engineers to develop an open-source application to track the real-time location of buses in city transit systems. *Time Transit* will acquire another layer of conceived space when we use urban anthropological research methods to analyze and interpret the text messages that were collected over the life of the installation. What kinds of content did the installation prompt users to create? How did it vary over time? What were the recurrent or one-off themes and modes of communication?

Tracing the City through Art and Anthropology

Our *Tracing the City* project will similarly create and trace public, interactive art installations through new avenues of anthropological and artistic inquiry. We aim to use locative media (GPS and GIS), cellphones and Web 2.0 interfaces to engage ‘the public’ – understood as people *and* places/spaces – in artistic creation. By layering dynamic data over physical space – for example, an architectural plane – we will create an augmented spatial environment that then becomes a tangible interface for the public, who collaborate to create the ultimate meaning of the work. The resulting artworks will be exhibited (installed, projected) in outdoor and indoor public spaces, becoming part of the sensory experience of the city, and will also have a virtual presence on the web. The project therefore engages with ‘the public’ in terms of both space and society. One site we are particularly interested in is Halifax’s downtown public library, not only because it is a quintessential urban public space, but also because, like Regina’s bus #4, it already has a public membership, a set of regulars, and is well integrated into spatial practice.

The anthropological component of the project consists of building in feedback loops that will both investigate how members of the public experience our artworks, and generate material for creating subse-

quent artworks. The research-creation process will be enriched by the contributions of three collaborators whose practices are connected to our own: Ellen Moffat, a sound installation artist based in Saskatoon; Christopher Kaltenbach, an interdisciplinary designer based in Halifax (NSCAD University) and Tokyo; and Erin Wunker, a cross-genre literary scholar at Dalhousie University. We are keen to find out how both the interdisciplinary collaboration among the research team and the interactive collaboration of the public will affect the structure and content of the artwork.

To come full circle back to Lefebvre, we will be engaging perceived, lived and conceived space in particular ways. We want not only to emphasize but to amplify the interdependence of imaginative space and everyday space: we want to bring spatial practice (perceived space) into representational spaces (lived space), making quotidian, routine experiences of the city alter and interfere with its resonant artistic symbols. This means bringing the banal events and objects of urban public space, both routine and haphazard, into the imaginative but typically personal world of art and culture. Moreover, by doing interdisciplinary 'research-creation', we want to draw on representations of space to make representational spaces – and, indeed, vice versa. Dialogue between artists and social scientists should enable the latter to creatively explore the conduct and consequences of arts-based inquiry, and the former to conduct rigorous research, particularly with respect to public interaction with and experience of their works. We recognize the paradox of, on the one hand, working to subvert and decentralize creative authorship, and on the other, turning creative processes into 'objects of study' and 'sources of data' that potentially nourish the commodification of urban symbols. But however codified and commodified they may be, representations of space still provide the knowledge that underpins our understanding of spatial practices and representational spaces. We take the opportunity of interdisciplinary collaboration to try working in the interstices between perceived space, lived space and conceived space. In these ways, we aim to make the public space of the city creatively intervene in the private space of engagement with art.

DIGITAL ANTHROPOPHAGY AND THE ANTHROPOPHAGIC RE-MANIFESTO FOR THE DIGITAL AGE

Vanessa Ramos-Velasquez

A theoretical essay proposing a new practice of consumption (ingestion, digestion, excretion) involving a technological mediation, and a manifesto-poem with a new take on the 1928 *Manifesto Antropófago* by Brazilian author Oswald de Andrade. I offer an update for the concept of cultural cannibalism in regard to the digital age, where the virtual world is the new frontier, and everyone a possible colonizer.

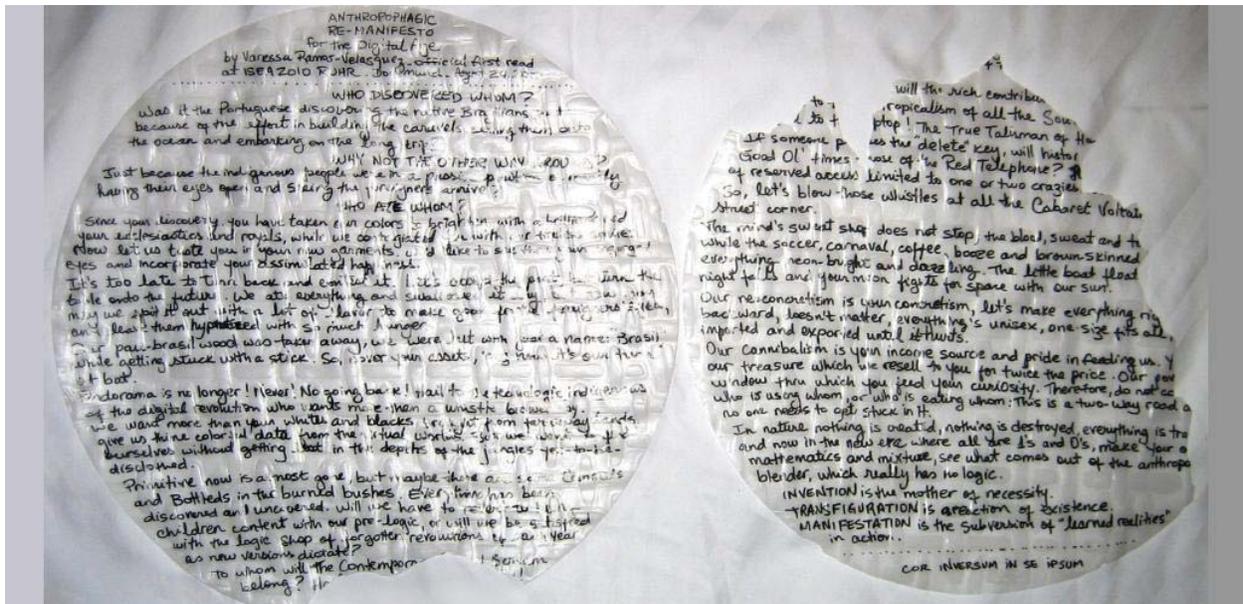

Fig 1. The Anthropophagic Re-Manifesto for the Digital Age

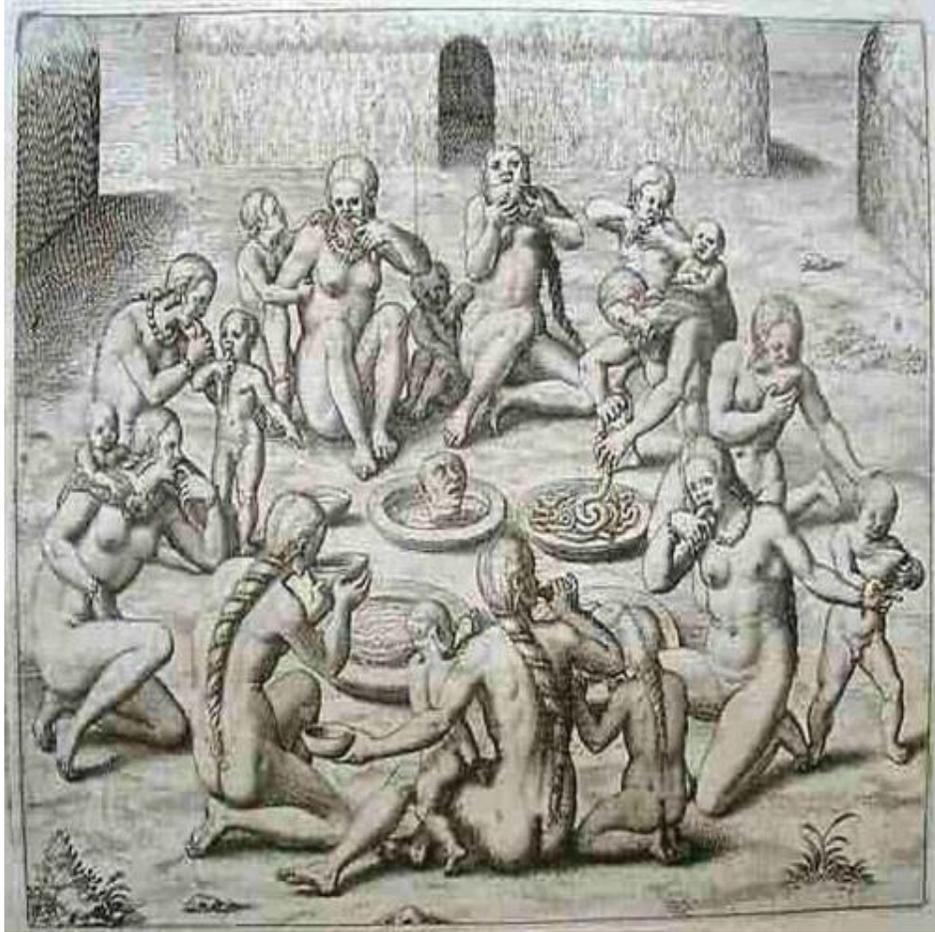

Fig 2. Anthropophagy

Fig 3. Digital Anthropophagy

ANTHROPOPHAGIC RE-MANIFESTO FOR THE DIGITAL AGE

Who discovered whom?

Was it the Portuguese discovering the native Brazilians just because of the effort in building the caravels, setting them onto the ocean and embarking on the long trip?

Why not the other way around?

Just because the indigenous people were in a passive position of merely having their eyes open and seeing the foreigners arrive?

Who ate whom?

Since your discovery, you have taken our colors to brighten with a brilliant red your ecclesiastics and royals, while we contagiated you with our tireless smiles. Now let us taste you in your new garments. We'd like to see thru your engorged eyes and incorporate your assimilated happiness.

It's too late to turn back and contest it. Let's accept the past, but turn the table onto the future.

We ate everything and swallowed it dry, but now may we spit it out with a lot of flavor to make good for the foreigners' eyes and leave them hypnotized with so much hunger.

Our pau-brasil wood was taken away, we were left with just a name: "Brasil", while getting stuck with a stick. So, cover your assets, 'cuz now it's our turn at bat.

Pindorama is no longer! Never! No going back! Hail to the technologic indigenous of the digital revolution who wants more than a whistle blower toy.

We want more than your whites and blacks brought from far away lands, give us thine colorful data from the virtual worlds. But we want to find ourselves without getting lost in the depths of the jungles yet-to-be-dis-clothed.

Primitive now is almost gone, but maybe there are some Canneds and Bottleds in the burned bushes. Everything has been discovered and uncovered. Will we have to revert to being children content with our pre-logic, or will we be satisfied with the logic shop of forgotten revolutions of each year as new versions dictate?

To whom will The Contemporary Primal Scream belong?

Hail to innocence and purity! May they never lose themselves in the post-modern emptiness of the Matrix, the new belly button of the world!

Hail to the ignorance of the infant unknown to pixeland!

This time, what will the rich contribution of all mistakes be?

Hail to the En-Tropicalism of all the Souths.

Hail to the Laptop! The True Talisman of Happiness!

If someone presses the “delete” key, will history be erased? Good Ol’ times those of the Red Telephone? It was just one button of reserved access limited to just one or two crazies. Now every loony has one!

So, let’s blow those whistles at all the Cabaret Voltaires of every street corner.

The mind’s sweatshop does not stop; the blood, sweat and tears run infinitum while the soccer, carnival, coffee, booze, and brown-skinned beauties leave everything neon-bright and dazzling. The little boat floats at sunset as night falls and your moon fights for space with our sun.

Our neoconcretism is your concretism, let’s make everything right, left, forward or backward, doesn’t matter, everything’s unisex, one-size fits all, made in China, imported and exported until it hurts.

Our cannibalism is your income source and pride in feeding us. Your trash is our treasure which we resell to you for twice the price. Our poverty is your window through which you feed your curiosity. Therefore, do not complain who is using whom, or who is eating whom. This is a two-way road and no one needs to get stuck in it.

In nature, nothing is created, nothing is destroyed, everything is transformed; and now in the new era where all are 1’s and 0’s, make your own mathematics and mixture, see what comes out of the anthropologic blender, which really has no logic.

Invention is the mother of necessity.

Transfiguration is a reaction of existence.

Manifestation is the subversion of “learned realities” in action.

FULL ABSTRACT

The background of my *Digital Anthropophagy* theory comes from the *fair use* conundrum of the Information Age. One of my own art practices is to create films from found footage and openly exposed media. I metabolize these materials into new contexts. In the creative process of this practice, in the age of the Interneted Information Society as the producer of culture also engaged in remixing, offering a rich self-serving online buffet, I often thought of the Anthropophagic practices of some Brazilian indigenous tribes when they came into contact with their colonizers. The indigenous cannibal honorably eats the foreigner in order to incorporate his strength, experiences and qualities and to see through the cannibalized foreigner’s eyes. But I find that in today’s digital culture, we unceremoniously consume the world around us in a globalized structure, thus quickly acquiring worldly references and spitting them out in a personal but also somewhat homogenized way. We have thus become both the cannibal and the cannibalized because of the wide and immediate access to information and the incredible reduction

of time it now takes to consume that widely available culture. It no longer takes a passive person watching the ships arriving on the shore in order to consume what they might bring aboard, and conversely, for the colonizer in those ships to take away the riches they “discover” in far-away lands. Over five hundred years later, that exchange has now become cross-pollinated and more equal, and happening in an inhuman speed cycle. And the paradigm of power acquisition has now shifted from land ownership of colonies to ownership of information and creative property, especially engendered by the virtual world. This virtual world has started to disintegrate former imperialism and push toward a “democratization of access” and “freedom of use” of information. And so I offer an analysis of Information Metabolism which drives human experiences. I hope this work furthers the discussion on fair use of media, leading to a simplification of global fair use cultural models and practices in the age of digital culture.

Background history leading to my Anthropophagic Re-Manifesto for the Digital Age:

In 1928, a Brazilian Modernist author, Oswald de Andrade wrote the *Manifesto Antropófago*, (the *Cannibal Manifesto*). It was an assertion of the unique Brazilian voice in the emerging modern time, away from clichés of colonialism, while unapologetically metabolizing outside references from the First World. Over 100 years since Brazil’s independence from Portugal, the moment of transformation had come! To devour outside artistic influences from Europe, and to finally incorporate all their developments useful to Brazilian culture, while seeking the Brazilian modern identity, strength and unique vision. It was as much a dictum against the colonizer’s power, as it was a criticism of the colonized people’s hunger for what is not their own. My manifesto-poem offers a new take on the original Manifesto and I call it a “Re-Manifesto”, alluding not only to today’s remix culture, but also to a re-assertion of previously colonized cultures into the new dynamics and context of cultural influence in the digital era. My *Digital Anthropophagy* position paper likewise, seeks to update that anthropophagic practice of cultural cannibalism to the digital age, proposing that the virtual world is the new frontier and anyone can be a colonizer.

In my Anthropophagic Re-Manifesto, I expose that the allure, the attraction of “the other” is mutual and that it serves to form a symbiotic relationship that feeds both peoples. The concept of “the exotic” is a two-way road, for if one has never seen the other before, their mutual discovery is of equal impact, and a curiosity to consume that newfound exoticism is occurring on both sides. The question thus is not about the symbiosis itself, but about the degree of positive influences and acculturation, especially in the era of an ongoing digital revolution. Of course the great line dividing this equality in colonial times was an economic one: the colonizer upon seeing a newfound land sees money, while the “found people” just sees unknown people. That very innocence of the Golden Age is the exotic raw material that so many in the First World seek, but beware as even in that innocence lies the cannibal spirit. And since there’s no more land to discover, the colonizer has now become the entrepreneur who seeks to conquer the virtual landscape of 1’s and 0’s. But now the “innocent” is born with a much larger capacity to understand and dominate that virtual world. So now the entrepreneur is forced to invite who he or she sees as the cannibals into the game in order to keep the barbarians at the gate. And these little barbarians will grow up to be the entrepreneurs of tomorrow in an endless cycle of digital evolution. Thusly, anyone will be a colonizer, except this time nothing is done by imposition because the networked community functioning as a universal brain decides what gets served up, and consequently what becomes consumable in this natural entropic filtering process.

My Manifesto-Poem is therefore a new take on the original *Manifesto Antropófago*. It is but a glimpse through a prism reflecting how the indigenous Anthropophagic cannibalistic practice resonates to

today's civilized society, materializing as cannibalistic remix culture spanning the entire world in an age where virtually all colonies have proclaimed their independence. It's the new world order: anyone can chose to be either the colonizer or the colonized, and why not both?

DIGITAL ANTHROPOPHAGY

INTRODUCTION

"Anthropophagy": anthropos = "human being" + phagein = "to eat". Main definitions:

1. Cannibalism, as the eating of human flesh by a human or humans
2. Self-cannibalism, as the eating of one's own flesh
3. Eucharist, the ceremonial eating of the body of Jesus as wine and bread

In my view, these forms of cannibalism have transmuted into a new form, which I would like to propose as *Digital Anthropophagy*, meaning:

1. All the aforementioned Anthropophagic practices if done virtually, for example, with the aid of computers, social online networking, and other digital devices; or if executed in reality but facilitated digitally
2. A new paradigm of input/output models generated via the internet
3. A new practice of cultural consumption involving a technological mediation for input (both the feeding and the being fed), digestion, and output

OVERVIEW

Cultural Cannibalism from tribal origins to today's cultural practices through a mash-up of Biological, Philosophical, Social, Economic, and Artistic perspectives.

- DIGESTIVE PROCESS OF CANNIBALIZATION: ORIGINAL RECYCLERS and REMIXERS
- DIGESTIVE PROCESS OF CANNIBALIZATION IN HUMAN BEHAVIOR: ACTIVE AND REACTIVE AGENTS
- CULTURAL IMPERIALISM AND TECHNICAL BARBARISM LEAD TO A REACTION TO DEMOCRATIZE
- ACCULTURATION MODELS ACCORDING TO A PROPOSED POLYMORPHOUS CANNIBALIST PRACTICE

CHALLENGES

Human nature reacting to widespread availability of information and culture. Uncontrollable hunger to consume what's available and facility of "public as producer of culture" leading to uncontrollable media usage in the form of appropriation and re-appropriation, memes as an example.

- CYCLES OF CONSUMPTION / MEDIA BOMBARDMENT
- APPROPRIATION
- RE-APPROPRIATION
- THE NEW TECHNOCRACY
- THE NEW CANNIBALISM: TO PROPAGATE OUR HISTORY AND TO SECURE OUR IMMORTALITY

PROPOSED SOLUTIONS

Considerations for a free and democratic internetworked society.

In practical terms, common sense should guide us in helping to decriminalize the very pillars of freedom of expression and access to information as they are paramount in the new socio-economic development. In his book "Remix", Lawrence Lessig proposes five steps to help us walk the path towards more efficient and sound copyright law.

My own proposed methods involve:

- Credit your sources whenever possible! If you don't know who or where the material came from, use a standard disclaimer that invites the audience to contribute the missing information, much like in the Wikipedia model.
- Use a pre-existing international forum, such as Creative Commons to further internationalize the simplification of copyright regulations into the Copyleft Model, and expand upon it to ensure owners of the creative property are getting paid in a fair method for the use of their work.
- If this model starts to fairly value the exchange of intellectual property, then Mafia-like organizations who collect money on behalf of artists will naturally become obsolete and disappear, just like in a process of natural selection and evolution.
- Treat other people's output as you would like yours to be treated, keeping in mind that imitation is still one of the highest forms of flattery, but that we have moved way past that simplistic form of content integration onto higher forms of remix culture and beyond, where everybody can win. New technologies will always bring with them new possibilities and probabilities that cannot be stopped or reversed. Therefore it is up to each of us to be creative in how not to lose profit but more importantly in how to gain new profit. And by profit I don't mean just money, but all that is made possible by being internet-worked. A new gateway to a new kind of enrichment.

A POTENTIAL LANDSCAPE

Jonas Ranft

Landscapes... Beautiful landscapes, of course: mountain ridges and beaches. The sea and the desert as they constantly evolve, retract & gain territory, change their very appearance. Did you know that not only does a wild sea roar but that dunes can sing? Landscapes are dynamic, and we're part of it.

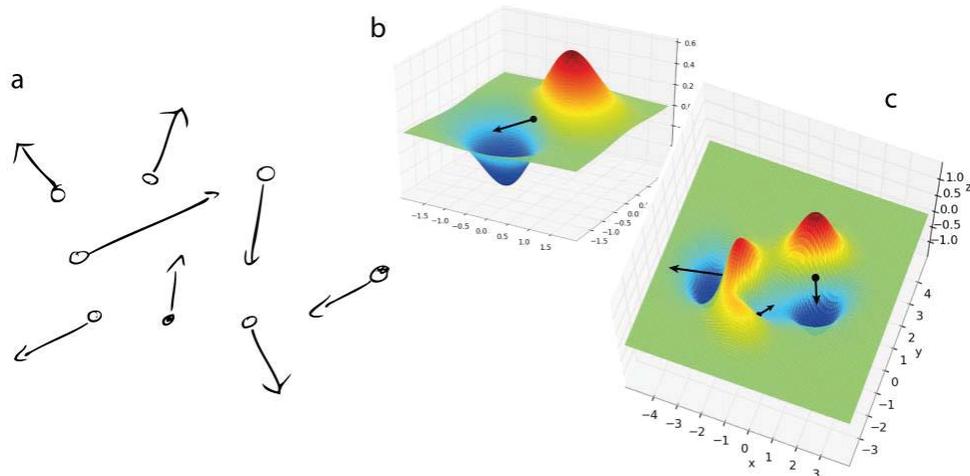

Fig. 1. (a) Sketch of agents that move on a plane, with speed and direction as indicated by the arrows; (b) the potential that corresponds to the motion of a single agent; and (c) the global potential landscape that accounts for the motion of all agents around.

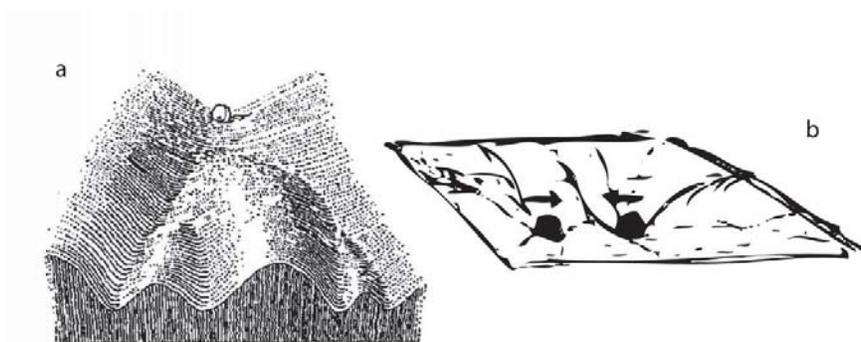

Fig. 2. (a) The epigenetic landscape as depicted by Waddington: The marble represents a cell that differentiates on its way down the valley, thereby experiencing constantly a new environment. (b) Sketch of two (actual) marbles on an elastic sheet which gets deformed, thus mediating an attractive interaction between the marbles.

```

Fig. 3. The potential that corresponds to a given motion is combined of a skewed plane and a Gaussian cut-off, in order to remain localized around the agent.

Imagine you have a bird's eye view of a public square full of people. Some of them stand together chatting, one or two sit on a bench reading the newspaper. Others are moving around, crossing the square hastily as to catch the bus on the other side or just because they overheard their alarm clock this morning, being in a hurry all day since; some stroll around without any apparent destination, changing their mind once in a while and turning direction. What makes all those people move, what determines their pace? In the following, we hypothesize that these movements in space and their evolution in time can be understood as a dynamical system whose "inner workings" we aim to uncover.

Let's consider this dynamics from a more abstract perspective. Figure 1(a) shows a sketch of some 'agents' moving in a certain direction with a certain velocity, a simple representation of a given configuration of people on the public square mentioned above. We can now rephrase the above questions: How does such a configuration arise? How do these configurations evolve? Which forces act on the agents, confer momentum, make them go? Here, we unveil an underlying potential landscape that ac-

counts for these forces and thus explains the observed movements. This potential landscape can be considered as kind of a socio-dynamical analogue of potential energy in physics. Think of gravity: An apple that falls from the tree accelerates due to the gravitational force; this force results from a difference in potential energy between the apple being high up in the tree (more energy) and down low in the grass (less energy). Analogously, it is the ups and downs, or gradients, of the potential landscape that describe the varying forces that the agents experience in time and space.

So how does this potential look like? If it determines our behavior, can we feel it? Where 'is' it? These questions are difficult to answer. No, we can't feel it. No, it doesn't smell. The potential is invisible, of course – but it defines a landscape that we can represent.

Dynamics of the Unseen

First, consider an individual, a single agent. In order to extract the potential from the observed motion, we assume that (i) the velocity in amount and direction is given by the slope of the potential at the agent's position, and (ii) the potential forms a smooth surface without abrupt jumps or kinks. This is illustrated in Figure 1(b), which shows the potential around a single moving agent. Analogously, we can reconstruct the global potential for more than one moving agents in the very same way, where the slope at any agent's position corresponds to its velocity, see Figure 1(c). This potential landscape, however, is not static. Foremost, this is a matter of fact: We change our mind – and in the potential landscape picture this implies that the gradients change, hills and valleys move, too.

This is unheard-of: From the wills of the gods via Leibniz' pre-established harmony to voices in modern neuroscience – ideas that our actions are determined have been around. But the underlying dynamics has never been exposed so explicitly, as something that we can see with our own eyes.

Just watch it! The hills and valleys defining the potential landscape sweep across the square, and all the people can't but move accordingly. A little chitchat here: two people that meet on a flat spot. As the potential starts to bulk out, they inevitably separate, moving in two different directions, drawn apart. Then that lady over there: hurrying along as the steep potential gradient pushes her forward... It is a smooth, ever-changing landscape that we observe, almost reminding us of a heartbeat as it goes up and down here and there. Importantly, it is a social fabric: It is a single, joint potential landscape that determines everybody's pace.

There is another clue to it: Now that people can 'watch' the forces they are subject to, they may react. Trying to escape that determination. I'll prove my free will! Will I be able climb that hill? Defy the laws of motion? The potential seems to be one step ahead, however: In fact, it corresponds instantaneously to their supposedly free actions, and inevitably everybody continuously seems to follow the line of steepest descent. This states the ambiguity of our approach: In reconstructing "A Potential Landscape" *a posteriori* from the observed movement, it is the movement that precedes the potential – constructing it in a way that it accounts for the movement, it is the potential that causes the latter. What truly remains, is the constitution of a new social space: Even if it seems that we can't defy the laws of motion, we will soon realize that together we can create all kinds of patterns...

Fiction and Epigenetics

No pseudo-scientific vocabulary like ‘force’, ‘potential gradient’, and ‘momentum’ can betray the careful reader: the unveiled potential landscape is of course purely fictitious. Let’s consider it as some kind of fiction, a story that is told, a game maybe. By taking it seriously, though, we might be able to learn something about dynamic landscapes in general. How can local dynamics be reconciled with the idea of a global, unified landscape? What kind of feedback can be conceived between a landscape and the dynamics of agents it might represent?

In the sciences, the landscape metaphor is recurrent: In biology for example, the epigenetic landscape provides a simple picture for epigenetic phenomena such as cell differentiation, serving as a means to explore by figurative analogy different aspects of the concept in question. In population genetics, the ‘fitness landscape’ – be it adaptive or not – describes the fitness of individuals with certain genetic traits; physicists speak about ‘energy landscapes’ when they refer to a system’s potential energy as a function of space. It is the epigenetic landscape, introduced by Conrad Hal Waddington in 1940, which is the paradigmatic example of a dynamic landscape that evolves in time. [1] Waddington, a biologist, was interested in the apparent contradiction that stem cells can differentiate into different types of cells such as muscle cells and neurons for example, although every cell contains exactly the same genome which encodes the building plan for all the molecular constituents of a cell. Necessarily, it is not only the individual genome, but also the environment of that cell, that determines the so-called cell fate, i.e., which type of cell it will develop into. The epigenetic landscape, see Figure 2(a), describes this process of cell differentiation: As a cell starts ‘at the top’, it rolls down the hill, following a broad valley which is laid out by the genome. Later, the valley splits in two, and for the future differentiation it is important where exactly the cell reaches the branching point. However, this landscape is not static either, for two reasons: When a cell differentiates, it (i) changes its own gene expression pattern, and (ii) is most probably subject to an altered external environment, which is both reflected by a modification of the landscape. [2]

The potential landscape introduced above mimics that idea: The movement of the agents follows the slope of the potential, and as they move the potential evolves accordingly. Because the potential is calculated from the observed dynamics – “Tell me your velocity, and I tell you your potential” –, it is kind of a reverse engineering approach; only that the result is pure fiction. But if we do not insist on the “predicting” character of the potential, we can see it from a different angle: The derived landscape is dynamic with a time evolution that is determined from the of localized agents. As such, it is a complementary concept of landscape dynamics. On the one hand, it seems to be the opposite of the complexity of the epigenetic landscape, for which external driving and intrinsic dynamics of the landscape are in constant interplay. On the other hand, however, in the epigenetic landscape picture, a cell’s course is not essential to the epigenetic landscape dynamics anymore: To the extent that the path of a cell follows the landscape, it is predictable from the landscape itself; to the extent that it is unpredictable, it is simply additional external input that has to be taken into account for the further time evolution. Whereas in the proposed potential landscape the landscape is nothing without the agents, the epigenetic landscape evolves and changes and adapts without necessarily including any cells at all in the picture.

Interaction

So what about the interaction between different agents? In order to answer questions like “How does A influence B and vice versa,” I will have to elaborate more on the algorithm according to which the global, multi-agent potential landscape is constructed. Let’s come back to the two necessary conditions

that qualify the extracted landscape as a (fictitious) potential of the observed movements of individuals. First, the velocity in amount and direction is given by the slope of the potential at the agent's position. Second, the potential should form a smooth surface without abrupt jumps or kinks and should not diverge at infinity. For a single agent, this is straightforward: We just combine a skewed plane of the right slope with a gaussian bell-like curve defining a cut-off, and we obtain a smooth function with the correct characteristics, see Figure 3. But how do we fulfill these requirements if more than one agent is present? If we simply added up the 'individual potentials' of two or more agents, the first condition would not hold anymore: We would obtain a smooth landscape, but with a slope different from the agents' respective velocities with which we started from. Somehow, we have to glue the individual potentials together in a way that the correspondence of slope and velocity is preserved. The motion of other agents' (B, C, ...) must not at all contribute to the local shape of the potential at the position of agent A.

This suggests that there is no interaction at all! This is true as far as the motions of the agents do not influence each other, which is intrinsic to the reverse engineering approach – otherwise the game could not be played, the agents' dynamics and the potential landscape would not be related in the stipulated manner. But as far as the dynamic of the landscape itself is concerned, the interaction can not be neglected: Whenever two agents are close to each other, the potential reflects this fact and changes its appearance! Whereas the people on a public square might not be coupled involuntarily by some real, hidden mental potential, they could well interact deliberately in response to each other. This is the social space referred to before: Once the proposed potential landscape is visualized in some way or other so that everybody involved can observe it, it opens up new perspectives on group dynamics and social behavior. It serves as a playground and catalyst for interactions that are not prescribed, but a response to the observed landscape dynamics.

This mode of interaction can be contrasted to actual, direct interaction, as for example between two marbles on an elastic tissue, see Figure 2(b). The weight of each marble deforms the tissue, which in turn guides the movement of the marbles towards each other. Such a system, however, is totally passive: Neither do the marbles choose a direction deliberately on their own, nor does the elastic tissue present additional forces that may drive the marbles apart. It would be worthwhile to construct an instance of a coupled system that tries to overcome such passivity, with a dynamic balance between active perturbation and passive response (see also [3] for experiments with "membrane landscapes").

The Potential Image

I want to discuss "A Potential Landscape" from yet another perspective. This landscape is an image. The potential comes to life with its visualization, visual representation. In principle, this representation has to be three-dimensional, be present, re-present in real space. Leaving the technical implementation (and limitations) aside: What does this dynamic image of hills and basins tell us? First, we notice that spatial structure is intertwined with evolution in time – there are no stationary structures, the height modulation corresponds to a temporal dynamics. Then, we may decipher that there is a connection between the potential and underlying agents, their movement and the dynamics of the image. But what do the hills signal? Are they not indicative of some kind of a presence, telling the observer "Here is what you look for"? Analogously, what do the basins tell us? We find that they are essentially empty, void of meaning. The agents are localized at the points of inflection, where the slope stops to grow and starts to diminish. Whereas the maxima and minima of a curve are defined only with respect to an up and a down, the inflection points are intrinsic to a curve independent of a defined axis. This is why Bernard Cache, an architect-philosopher, calls these points "intrinsic singularities" and considers them as the

“primary image” - like an image atom - from which whole territories are derived. [4] I want to close with a quote from his book *Earth moves*, which captures the image aspect of “A Potential Landscape” remarkably well:

“Just a hill and a valley and nothing more allow for all possible becomings. Space is thus no longer a juxtaposition of basins but a surface of variable curvature. We will no longer say that time flows, but that time varies. No settling is possible in such a landscape: variable curvature turns us into nomads.”

VISUALISING EMOTIONS AND AUTISM

Barbara Rauch

The e_Motion research proposal integrates 3D visualization, haptic technology and rapid prototyping as a window into the Autism Spectrum Disorders (ASD) mind. It represents an exciting evolution of past work done on emotion and digital media. Through the research of Simon Baron-Cohen and others we have learned that ASD falls along a broad spectrum.

Preface

It is now well known that many ASD people are visual thinkers and learners, and this paper proposes new research to utilize state-of-the-art but 'APPROACHABLE' digital technologies that will allow the autistic person to speak with distinct and enhanced visual voices. This differs from art therapy in that it will lead to a better understanding of how ASD individuals think and feel, through visualization. That the products of creativity might allow psychologists and neuroscientists to better place individuals along the ASD spectrum is especially critical.

This research paper outlines a unique contribution emphasizing emotion and visualization through digital 3D production and haptic technologies. The project is still in its early stages of production, however it has initiated the outlines and hypothesis of a promising cross-disciplinary study that also introduces a PLAY method for emotion rehearsals.

Introduction: Engaging Autism at e_Motion Lab

The discussion of affective computing that Rosalind Picard introduced in the mid-1990s is rather interesting to me when it comes to machines learning about affect and emotions. If we claim that we are ready to produce synthetic emotions to build affect in robots, we seem to know a great deal about them. Here, I am concerned with finding out what happens if emotions go wrong. At 'e_Motion Research Lab' we work together and investigate with the autistic person, or more correctly the person on the Autism spectrum disorders (ASD) who serves as a case study for a malfunctioning of emotion handling. The autistic person's main goal is twofold: it is to learn to read and respond emotionally to signs of emotions and of equal importance to experience emotions in their full meaning. It has been questioned whether the autistic child can actually learn to experience true emotions. I am investigating in the floor-time approach introduced in 'Engaging Autism', a book by Stan Greenspan, in which he delivers thorough research that helps autistic children to relate, communicate and think in a meaningful way. The work suggests that the psychology therapist has to examine the developmental stages of the very young child and go through the learning processes with the child (and parent) step by step. They initiate creative situations by employing a Play methodology. What I bring to this approach is the use of haptic and

tactile interfaces to generate and also measure emotional feedback and affective creation. I suggest that the haptic technological interface research might enhance emotional and affective experiences through the hands-on creation process.

Intersubjective Approaches to Influence Emotional Communication

How do we learn a language and/or social skills? We seem to build on personal experiences; we create a model of the world that is being constantly updated. However emotions are very subtle and the autistic person seems to be less tolerant of emotional responses that differ from the model they had just adopted. By this I mean to introduce the subtleties of facial or bodily gestures that communicate all shades of emotional correspondence.

The problem with emotions is that we need emotions to make creative choices but also emotions and feelings are necessary in order to make rational choices. Affective computing talks about this problem of affect and emotion not being the same: affect is central to our understanding of culture, in particular to the postmodern debate; the body and its capacity for sensation is informing cultural theory - its discussion about how society and humanity are far more complex, and cannot be reduced to a diagram. Picard (1996:1) defines affective computing as “computing that relates to, arises from, or influences emotions.” (She coined the term in the mid-1990s.)

My earlier attempts to visualize emotions came into being when I worked on a study about facial expressions. I employed Paul Ekman’s understanding of universal emotions, expressions of the face that can be understood across cultures. His classification of basic emotions into a list of six distinct emotions (anger, disgust, fear, happiness, sadness, and surprise) was later extended to include guilt, contempt, shame and others. I initially used a list of seven emotions by adding contempt to the original six basic expressions. This allowed me to select distinct facial expressions in the human face that are identified with being happy, sad, disgusted, afraid etc.

Through a previous collaboration with the University College London I had access to a large 3D database of the human face, where I suggested adding new scans, namely scans of a smiling, frowning, surprised or disgusted face of a man. Furthermore I was interested in discussing the evolutionary aspect of emotions, not unlike Darwin’s interrogation of expressions of emotions in animal and man. I therefore included a fox’s neural expression in the very same large database. This allowed me to morph not only from a happy to a sad person, but I could now also animate the face to become more fox-like, with a happy or sad expression on its face. This model will be used in a study to test facial expressions and mimicry in the autistic person.

Several research creations were produced using this large database. Works include ‘emotional degrees’ (animation), ‘interFaced’ (sculptures), and ‘friends’ (hybrid digital representations of merged faces). I will include images of these works. Copyright Barbara Rauch.

In his book ‘Emotions Revealed: Recognizing Faces and Feelings to Improve Communication and Emotional Life’ Ekman (2003) describes the importance of the face in human communication. We all recognize a smile, we mimic it and so does the infant child.

The autistic child however might not return a smile, and it has been discussed whether this is due to the child not being able to read the emotion of the mother more generally, or if this is due to a frustration

caused by the child not being able to clearly identify or classify slightly different emotional expressions on the face.

The study of emotions in autistic people has been addressed by numerous researchers, and one particular theory is of importance to my research and this will be elaborated here. When discussing the issues of emotions in humans we relate concepts of consciousness, mind, empathy, and evolutionary biology, animal study and social neuroscience; all of the named concepts address the debate of an emotion theory and the theory of mind (ToM).

If a subject has an understanding of self and other, place and time, the person will be able to simulate a situation or even imagine someone's thoughts and intentions. And this is what seems to go wrong in the autistic child's mind. Theory of mind impairment sometimes referred to as mind-blindness discusses the inability of the autistic person to understand that another person has her own thoughts, this of course also includes feelings or emotions in response to particular incidents that the other person might experience.

Imitation, mentalizing and empathizing are skills that the young child acquires by mimicking and learning, however it seems that the autistic child might not have a very robust theory of mind (Baron-Cohen 1985). 'Theory of Mind' is what Baron-Cohen refers to as 'social reciprocity'. It is important as a social skill to pay not only attention to others, but also to others' intentions. The learning of other and self is usually mastered by a young child of 2 years of age. (See chapter 2, PhD thesis, Rauch 2006.)

The ability to imitate, mimic, mentalize etc., allows social-cognitive achievements, perspective taking, empathy: all these are the base for a theory of mind. The ASD child does not mimic the mother's gaze or smile, because it seems she cannot read exactly, as the face might vary too much for the ASD's liking of systematic answers and clarity in the expression. There is fascinating research on the interaction of the autistic child with robot toys that confirm this bold statement (Kaspar the friendly robot or soccer-playing humanoid robot Nao have both been developed for use treating autistic children).

Stanley I. Greenspan in 'Engaging Autism' (2006) points out how important early signs of autism in infancy are and in describing and advocating the floortime approach and the DIR program parents and therapists can intervene and help the autistic child to learn how to develop social skills. Greenspan reiterates how important it is to learn each step in the development. One has to be able to engage in basic attention, to be able to share a world to be able to develop higher levels of abstract thinking. And since this is one of the main problems that have been identified in autism, 'e_Motion Lab' research takes the specific object and then generalizes it to create a prototype image or memory of it. The digital data can then be treated like clay or other materials to manipulate, pull and push the data to play with iterations of the very same prototype.

Temple Grandin's work in 'Thinking in Pictures' encourages visual thinking over verbal expression. She talks about the frustration that the child will experience by not being able to label and express a particular emotion, resulting in the child's turning away from emotional data and instead concentrate on objects, toys or systems that are more reliable. By introducing models that the ASD person can identify with this will be a huge opportunity to create specific and recognizable representations of emotions almost on demand. The lab is linked with an adjacent rapid prototyping set-up where we hope to introduce 3D printers that range from handling material output that is soft resin, hard and porous plastic/ceramic shell and paper modeling using lasers, additive and subtractive sintering machinery.

Temple Grandin elaborates on her particular interests in systemizing designs. She explains that the ASD has developed a hypersensitivity to detail and individual blocks of information. ASDs often are talented in the breaking down of complex models or designs into small parts.

Grandin is a high-functioning autistic person, and in the near future we will be working with ASD adults and ASD artists and designers who would be encouraged to work with complex data sets; they would be touching the data using haptic and other sensory tools. We speculate that their particular sensitivity with touch and feedback will produce a unique body of designerly and artistic work. The fluid data set would offer a rehearsal situation for their emotional frustration, they will be altering faces or change objects to their liking. And I hypothesize that this body of work will be revealing insights into the unique haptic and sensory skills of the emotionally challenged ASD. (REB approval in process.)

As mentioned above e_Motion Lab works not only with autistic people. We collaborate with artists and designers on creating through haptic devices and visualization tools and techniques. We recently received funding to stage a PlayShop workshop series employing a Play Methodology. My particular workshop hopes to deliver insights into emotions and feelings and the use of technological tools and to apply these findings to enhance the potential expression of emotions for the ASD person.

Emotions and feelings are probably the most confusing phenomena for psychologists, biologists, and those working in general in the sciences and humanities alike. Artists and designers have over the centuries devoted themselves to work on questions of and around consciousness and emotions. This is not just because emotions and their expressions often withdraw themselves from verbal reports but they are expressed equally both internally as feelings and sensations and externally as bodily gestures or facial expressions.

Being such a complex issue many influential researchers have engaged in emotion studies; Charles Darwin was as an early figure of evolutionary biology and William James (1890) an early key proponent of the psychology of consciousness; Dennett as a contemporary philosopher within cognitive studies, and his method of heterophenomenology, when it comes to the study of one's own mind. But if it is for Dennett we are all just conscious robots. On the other hand Joseph E. LeDoux and Antonio Damasio confront us with their neurological views. In *Descartes' Error* (1994), Damasio outlines how important emotions are for rational decision-making. He explains that reason and emotion are not separate; instead, mind and body need to be examined and explained in tandem. Damasio also explains the difference between emotions and feelings, as emotions happening in and with the body, while feelings are reflective and conscious experiences in the mind.

For facial expressions, emotions and bodily emotional gestures I want to highlight here again the work that Paul Ekman has done over many decades. Ekman's examples of how to read emotions on faces will be explored. Ekman created hundreds of photos; some are collaged works since they are difficult to make on demand. One approach in the workshop will be to improve our ability to read the face of the other. We will mimic and play with toys, so as to create a basic means of communications between ourselves.

We will study Robert Plutchik's psychoevolutionary theory of emotion in more depth to employ his wheel of emotions in our Play workshop session. If we consider his elaboration on emotion and cognition, emotions are really developed to help predict future events. Emotions are there for survival of the species and they serve as cognitive information about our environment. In that sense they are not linear events but feedback processes, they are in loop to restore a state of equilibrium in the body. This is true

for internal as well as external stimulation i.e. dreams trigger much of our emotion processing in the amygdala of the brain, where emotional data is mainly being processed.

As for the planned three-dimensional colour wheel for emotion concepts, Plutchick has developed a 'circumplex' model that not only represents emotions and their intensity but also explains how emotions can be combined. In addition the wheel has been used as a tool for personality labeling. I would hope that by playing with the model we will also examine how we relate to each other's emotional states.

The e_Motion Research Project (e_MRP) looks into Autism Spectrum Disorders as a model for understanding the mind of the other. With facial expression and reading emotions through an intersubjective approach, we explore both the relations with oneself and an object and the manifold relationships between subjects and externalized others.

Through these imaginative play or pretend play situations we create scenarios in which one engages in make-believe situations. Imagination and pretending helps children and adults to rehearse actions and sequences of actions; they can play out their ideas so as to rehearse for later in real life situations.

The Play Methods Workshop will be considered such a rehearsal situation. We aim to visualize the information we have gathered and hope to come up with some infograph/ sketches for the sessions. It is hoped that the visualization employs Csikszentmihalyi's theory of flow, the 'optimal state of experience' and deep immersion in the experience of one's self.

STICHTURES: INTERACTIVE ART INSTALLATION FOR SOCIAL INTERVENTIONS

**Claudia Rebola, Patricio Vela, Chauncey Saurus,
Tayo Ogunmakin & Jorge Palacio**

The purpose of this paper is to describe the design and development of Stichtures-interactive art installation for shared spaces. Physical and digital co-design activities are described in the development of the piece inspired by biological systems and collective behavior. The combined methods respond to the specific aims of the project, which investigates the effects of design and technology interventions on aiding interactions among people.

Stichtures

by
Claudia Rebola
Patricio Vela
Chauncey Saurus
Gbolabo Ogunmakin
Jorge Palacio

Stichtures is an interactive art installation for people. It is a dynamic piece that encourages people to interact with it. As the interaction occurs, the art installation evolves. Consequently, inclusion at the art installation is dependent on the interaction of individuals with both single and multiple individuals. The installation consists of a series of overlapping three-dimensional spheres, inspired by everyday objects. Interactions with the art piece occur via sensing technologies that are informed by biological systems. As people approach and interact with the art installation, visual feedback of shifting modalities invite, motivate and engage users.

no caption

INTRODUCTION

Interaction with other individuals seems to be a simple operation but may represent a challenging task for some people. Shared common areas in public spaces are great opportunities for interaction. Yet, sometimes they are highly underutilized. Designing interactive art installations for shared common areas

in public spaces can help people counteract lack of human interaction. An interactive design that benefits and grows from the involvement of multiple people may allow individuals to connect through interactive creation. The purpose of this paper is to describe the design and development of an interactive art installation, *Stichtures*, for shared spaces. The specific aim of the project is to investigate the effects of design and technology interventions in aiding interactions among people.

STICHTURES FRAMEWORK

The overall goal of the project is to investigate the effects of design and technology interventions among older adults in common shared areas. We identified different motivations to develop *Stichtures*. One is related to increasing interactions among people. Another motivation is related to bringing people closer to nature and art. Lastly, motivating people to move is of central importance.

Stichtures is an interactive art installation for people. It is a dynamic piece that encourages people to interact with it. As the interaction occurs, the art installation evolves. Consequently, evolution of the art installation is dependent on the interaction of individuals with both single (one individual) and multiple (multiple individuals) contacts. The installation consists of a series of overlapping three-dimensional patterns inspired by everyday objects. Interactions with the art piece occur via sensing technologies that were informed by biological systems. As people approach and interact with the art installation, visual feedback of differing modalities invite, motivate and engage users. The next sections describe the design and development of *Stichtures*.

PHYSICAL AND DIGITAL CO-DESIGN

Designing an interactive art installation encompasses design in the physical and digital realms. These realms cannot be separated. Instead of foregrounding the creation of interactions and interfaces that map onto and access digital information, there is a need to explore when and how digital computational media can be drawn back to the physical environment and how physical interactions can model digital behaviors. [1] This practice can be referred to as physical and digital co-design. Co-design requires a collaborative and interdisciplinary team. As such, different disciplines including industrial design, human computer interaction, and computer vision were brought together to respond to the needs of designing an interactive art installation.

CONCEPTUAL DESIGN DEVELOPMENT

The design of this project began with team members from industrial design. Early explorations involved studying how to materialize interactions and how those physical representations can coexist with digital interactions. Initial explorations included developing concepts that addressed the ability for technology and design to contextualize users withdrawn from their surroundings. The design team began with a focus on studying patterns. One of the earliest considerations used analog cell phone flashers (flashing LEDs from frequency waves) to create reactions within a patterned system. In this version, the intention was to bring attention to the effect of self-isolation on one's surroundings and helping others realize that they are continually involved with their environment and those around them. The issue of the concept was limited by the fact that the end user would not consistently use such technologies to activate the interaction as expected.

During this phase, the team focused on studying examples of interactive art installations that were interactive and reactive. Wall projects include the Adobe interactive installation; [2] the Aperture facade installation with interactive and narrative displaying modes consisting of an iris diaphragm matrix, whose variable diameter is the main interaction with the piece; [3] and the Living Wall project, [4] which aims at creating electronically enhanced wallpaper with touch sensors, LED's and Bluetooth technology, allowing users to touch decorative elements of the wall to turn on lamps, adjust heating, or activate a stereo. Lastly, the interactive wall Mes Etoiles responds to proximity of people. The closer one gets to the wall, the larger number of dots are light up in the surface activated by the embedded proximity sensors and LEDs. [5] All these examples represent a way of using designed surfaces for people to communicate or to build collective creations using their bodies as instruments.

Having examples of interactive art installations, Stichtures iterations focused on surfaces development. Investigation of patterns included developing a moodboard containing references to adult's everyday objects such as clothing, linens, upholstery, décor and jewelry. The goal was to lead design decisions around familiar forms while avoiding the presence of obtrusive devices that may intimidate or discomfort the users. This approach responded to the need of bringing about a physical design that was familiar to our end user.

As the refinement phase of the pattern progressed, a repetitive floral motif emerged, similar to a quilt. Quilts are physical comforters made of repetitive patterns traditionally composed of three layers of fabrics combined using the technique of quilting. Meaning, the joining at least two fabric layers by stitches. This allowed the team be inspired not only to develop a layered three-dimensional pattern but also to use conductive thread for stitching the pattern as a unified installation. Quilts also evoke the idea that users are building this piece by stitching together the sections of a whole. Simultaneously, it also allows the design to be linked to nature by emphasizing the plant and floral aspects of the form.

Digital interactions were also biologically inspired. By looking at nature as a source of inspiration and innovation, the art piece's core idea was framed on behaving like a living plant that requires care and attention (interaction). Through different versions, formal designs were simplified, abstracted and molded individually from natural variations of the Clematis flower (Clematis Vitalba, Clematis Jackmannii, and Clematis Stans respectively). As an integrated pattern, forms were refined by looking at the behavior of the liana. The liana vine uses trees and other vertical support to climb canopies to reach sunlight. This intertwining concept was adopted. The art piece was the designed with growing sections that permanently light up and, like the liana, they go from piece to piece and connect all the pieces as the art piece grows.

The final design consists of several layers containing a total of 52 modular pieces and distributed in a designated area of 97.25x84.50x10 inches from the actual retirement community common shared space. There are three different types of layers, which have a distinctive pattern designs. One of the layer designs covers a grid area of 4x4 modules with 16 modules. Each module is 21.75 x 21.75 inches. Additional layers cover a grid area of 4x8 modules with 28 modules. Each module is 21.75 x 14.75 inches. All modules are cut from transparent acrylic, of which two of the three distinctive designs are white fabric backed. These are attached by architectural aluminum rods, which allow the hard wiring to run throughout the piece. All modules are hand stitched with conductive thread to bring power to LEDs. Each modules hold white colored LEDs.

In order to promote a more natural form of interaction with the art installation, the interactive technologies development phase was based on behavioral patterns found in nature connected to communication. For example, behavioral communication patterns were noted in how animals interact at close proximity. As input mechanisms with the art installation, proximity patterns were defined to provide an active area large enough for two or more people to interact with the piece and prevent situations where users get drawn too close to each other that it repels them or too far from each other that they don't interact.

In terms of output mechanisms in the art installation, there was a need to provide an unspoken language that is easy to recognize to the users. Blinking was defined to lure users closer to the piece. The design decision was inspired by fireflies and how they use blinking lights to lure their mates. Additionally, the monochromatic white light and fabric mimics species without defenses that need to blend with the environment. [6] This mimicry creates a more relaxed invitation that uses the idea a defenseless animal to make the piece approachable instead of using the shocking invitation of bright colors to bring users into interacting with the art installation.

The result is an interactive art installation where the only form of feedback is through the use of monochromatic light. Sets of white LEDs accentuate sections of individual modules becoming the voice of the piece. Approximately 2000 LEDs create a series of organic patterns in three types of interactions: invite, engage, and motivate. Each interaction has its own method of communication (see figure 5). For the invite interaction, blinking is used to attract users to the art installation. Once an infrared range finder detects a user in its 5-meter sensing range, the LEDs on the outermost layer starts blinking (pattern #1). As the user gets closer, the blinking slows down until the LEDs become permanently on.

At close proximity, the piece focuses on the engage interaction. This form of interaction is centered on real time feedback that responds directly to users' actions. Phototransistors detect shadows casted by users and immediately respond to the user's actions by creating dynamic light patterns in the back layer of the piece (pattern #2). The more users simultaneously interact with the piece, the more patterns become lit up.

Finally, to encourage users to continue interacting with the piece, the motivate interaction is implemented. Inspired by plant growth, the motivate interaction is based on the amount and type of user input. As users interact with the piece by activating the phototransistors, sections of the last layer (pattern #3) permanently light up. This permanently lit state represents the growth of the plant with ivy like shape. The more users interact with the piece, the more the plant grows and the more sections of the piece permanently light up. To control the growth rate, a timer determines when the next piece should light. The count is renewed when a new section is lit. Conversely, a second timer initiates to control the to decay of the plant, turning off sections when no interactions occur. Additionally, the piece accounts for collaborative actions in the motivate interaction mode by only lighting the center sections of the circles when two or more people interact with the piece.

CONCLUSION

Bringing design and technology to common shared areas in public spaces may increase social interaction among people. This paper described the physical and digital co-design of art pieces inspired by nature. Designing art installations to aid social interaction remains to be explored. Yet, Stichitures was designed to be an interactive installation that creates an environment which proliferates communication through

the meeting of design and technology. This dynamic piece encourages people to interact with it, which causes the art piece to evolve. However, the evolution of the piece depends on the interaction of multiple individuals; a single individual will only have a temporary effect on the piece. The co-dependence on others inspires communication between individuals, which builds to create a greater sense of connection on a human level.

ACKNOWLEDGMENTS

We thank the Intelligent Vision and Automation Laboratory (IVALab) for their support and work in the project. We also thank the D-Matters Studio Lab and the School of Industrial Design at the Georgia Institute of Technology for their financial support towards developing Stitchtures.

FLYING ROBOTIC ARTS FOR HRI AND INTERFACE RESEARCH

Nicolas Reeves & David St-Onge

The SAILS research program consists in developing geometric objects that can stabilize, move and rotate in the air, and that are able to develop behaviours and assemblages through emergent processes. This paper will focus on the qualitative results of this massively interdisciplinary project, which presents many examples of situations where questions and needs required by the art realm have led to technological premieres.

1 - Introduction

The use of machines to convey impressions and emotions is everything but new. They are reports of vapour-activated automata, designed to impress worshippers in ancient Egypt. Human-like or animal-like automata were a trend in XVIIIth century Europe. As impressive as they might have been, these machines were seldom considered as art pieces at their time: they were more considered as pertaining to advanced crafts than to Beaux-Arts. Some were seen as amusement, or as demonstrators for their author's technological skills; others were scientific devices, meant to explain or understand biological phenomena. It is only by the end of the XXth century that robots began to be created for solely artistic purposes. From then, the progressive development of efficient automated learning processes, supported by the availability of sensors of all kinds, quickly led a part of the art community to create robots whose only objective would be to generate artificial emotions and impressions through interactive processes.

The SAILS research-creation program was originally developed for such purposes. Developed for now more than five years in the NXI Gestatio Design Lab, directed by Nicolas Reeves, it aims at developing autonomous cubic flying robots for artistic performances and exhibitions. It brings together engineers,

scientists and artists in a unique collaborative work process. [1] [2] The *Tryphon* is the latest aerobot developed within this program. It consists in a cubic polyurethane bladder surrounded by a cubic exoskeleton made from composite materials. Its overall size is 225cm. The Tryphons' predecessors were the prototype M180t (180 cm) and M170t (170 cm) *Mascarillon*, whose structure was made of basswood, and the M160c *Nestor*. This paper will discuss five performances with the flying cubes that occurred within the last years, focusing on the reactions that these objects triggered among various audiences.

2 - ROM<evo>

This performance took place at the Quebec Museum of Civilization in 2006. Three flying cubes, floating in a closed room, were programmed to avoid obstacles. The entrance of a visitor would trigger a series of events. First, one cube would stabilize in front of him. Then an external, adaptive video projection system would map on two faces of the cube the eyes of a hidden actress, whose voice, coming from hidden speakers, started a discussion with the visitor. The actress could actually see and hear the visitor through a microphone, a headset and several video screens. The scenario of the performance was similar to a robotic version of a Turing test; the actress was instructed to speak as if she was a machine, unable to understand the subtleties of a human language. For the robot, every word, every sentence was to be interpreted as a code: a system where each expression corresponds to one and only one meaning. It was unable to understand second-degrees, analogies, or metaphors. It began the performance with almost no knowledge about humans, and tried to accumulate information through its limited exchanges with the visitors.

A wealth of intriguing reactions intervened. Small babies were particularly attracted by the cubes. This was all the most surprising: apart from the gigantic projected eyes, no element of them could recall anything from human or animal beings that babies generally like. One hypothesis is that the slow oscillations and movements of the cube, which constantly repositions itself through its sensors and ducted fans, was seen by the toddlers as evoking a soft, gentle giant organism.

Another visitor spent a long time trying to teach a poem to the aerobot. The interesting point here is that the language of the cube is diametrically opposed, on a semiological level, to a poem: where the former tries to look like a code, a closed system where the meaning of each word is precisely defined, the latter corresponds to a form of text that is open to various meanings and significations. One can make the hypothesis that the visitor, knowing that the cube was eager to relate with humans, was trying to teach him a form of communication - art - that remains the privilege of mankind ; and to tell him implicitly that no real exchange would occur without a basic knowledge of the role of art on human communication.

Another curious event occurred when an old lady came into the exhibition room and began telling about herself to the cube. She came several times, and she talked about her feeling of loneliness; she explained that her children never visited her; and so on. Such a speech is not that surprising for an old woman; what is more intriguing is the fact that she could talk so freely about intimate matters to a huge cubical machine. Here again, we can only make hypothesis about her behaviour; but she certainly anthropomorphized the flying object to a degree. The presence of the projected eyes may have helped in that respect, but this is all but sure, since other visitors were literally scared by them. It may be more fruitful to compare this situation to a psychotherapy session: she may have seen in the cube an empathic entity that, precisely because it is so different from a human being, would not put any judgement

on what she was saying ; she could talk to it as long as she wanted without detecting on the cube symptoms of impatience or boredom that people frequently encounter when they repeat the same story several times.

This event also led to unexpected kinds of interactions. When a visitor was entering the room, the air currents created by his displacement and by the opening doors drawn more power from the cube's ducted fans, whose noise became louder. This created a supplementary reaction of the aerobot to a human presence. The same thing happened when groups of several excited youngsters came to speak together with the cube. Since their displacements were triggering air currents, and since the sensors detected more agitation, the cube looked excited as well, through its own reactions to the air flows, and through the reactions of its motors, which were striving to restabilize it.

Another intriguing observation has been made: the answer of the question to know if a human being was hidden somewhere in the system depended closely on the formation and education of the visitor. The people who were the most successful at finding the real answer were coming from the art community. Most scientists were convinced that the whole system was robotic, and that it included advanced modules for language interpretation and generation. It is worth remembering that no such modules existed in 2006, and hardly exist today. Further discussions revealed that the elements that led some people to find the answer were actually linked to very subtle changes and modulations in the eyes and voice of the actresses; these changes could never, for them, be generated by a machine : they could only be human. It is precisely this kind of observation that has the potential to open research tracks in psychology, HRI, neurosciences, and the like. This experiment led us to consider the impact on visitors of a similar aerobot whose vocal interactions would use a completely artificial system, based on a voice-recognition program coupled with an artificial locutor. This development has become one of our priority research axes.

3. The Summers of Dance in Paris

No direct interactions with people were planned for this event, which was seen only as an opportunity to test autonomous interactions in difficult circumstances, with large audiences. The aerobots would try to mimic human movements through their own translation/rotation vocabulary. All displacements were made through assisted, partially automatic remote control.

In the summer of 2008, we were invited to fly three Tryphon cubes for the Summer of Dance in Paris, within the gigantic nave of the Grand Palais. In such a space, the air streams caused by convection and differential pressures generate an aggressive flight environment. All the mechatronics and stabilisation algorithms had to be completely redesigned prior to the event, in order to ensure proper a behaviour of the cubes over a dancing crowd, in such a wide space.

Calibration times were particularly long because of strong air streams, and the system only worked properly on the second performance. The first performance had to be made through semi-autonomous remote control: the movements of the aerobots were partly induced by direct commands from the pilots, coupled with self-stabilization and collision detection. Our degree of control on the robots allowed us to make them act like dancers in the air, or even on the dance floor. Their movements were determined mainly by the reactions of the pilots to the music, which were themselves influenced by the general energy of the crowd: they became the equivalent of proxies for the pilots, of whom they became a sort of cubic flying embodiment. The audience seemed to share the space with a different and new kind

of dancer; the other dancers had to adapt to the presence of these huge moving objects, and to learn how to predict their movement so as to give them sufficient space to evolve.

4. Nestor and Veronique

This event took place in the Montreal Center for Sciences. It was the first completely interactive performance involving an actress and an autonomous cubic aerobot. It was based on a simple scenario, in which the actress would tame a Nestor flying cube by interacting with it through her movements and displacements. Each interaction was fine-tuned to be as precise as possible; but there is no way to predict exactly the behaviour of an aerostatic object in every possible circumstances. An interesting evolution occurred during the event : since the actress had to adapt her movements to the slow pace and to the unexpected movements of the aerobot, the performance progressively developed into a two-ways relationship, just like if the particular behaviour of the aerobot had influenced the behaviour of the actress. After several shows, everything happened as if the unpredictable movements from the cube induced the actress to react on an improvised, almost choreographic manner, which greatly enriched the performance. Some other unplanned reactions were caused by small drifts of the cube, when it was caught by sudden air streams; they actually added an anthropomorphic touch to the cube's behaviour, since small errors and imprecisions are more easily associated with humans than with machines. To our knowledge, this performance was the first experiment involving an interaction between a human being and an autonomous blimp.

5. Geometric Butterflies

This performance took place in Moscow during the spring of 2009, as part of a Science-Art festival. It was the first long lasting, totally autonomous performance for the Tryphons. The cubes were flying in an area surrounded by blue spotlights. They were instructed to avoid obstacles and to run away from light. The spotlights sent them towards the center of the flight area, where they met randomly with each other; their obstacle avoidance algorithms sent them back to the periphery, where they would detect again the light sources, and so on. This sequence created continuous, unpredictable orbits. When they were getting too close to each other, their collision detectors reacted quickly, at times sending them towards and over the audience. The approach of these huge objects was impressive: the visitors would quickly extend their arms to stop them. This was sensed by the detectors, which sent the cubes back to the flying area, creating a first occurrence of interactions between the cubes and a whole crowd.

Other kinds of interactions happened. Even when the Tryphons were in a near-stable position, the visitors tried to interact with them and to make them react through the light of their cellphones. This desire to communicate with the aerobots and to influence their behaviour through individual or group interaction brought us to the conclusion that any future performance with the cubes, even theatrical, must consider the audience as an integral component of the environment, and should benefit from its presence to develop new ways of interacting.

6. The Floating Head Experiment

This HRI-artistic public experiment took place in Montreal in 2010. It was the result of a many-months collaboration between our lab and the team of Australian artist Stelarc. [3] A Tryphon aerobot was combined to Stelarc's work *The Prosthetic Head*, which consists in a 5-meters-high projection of a 3D avatar

of himself, represented through a synthetic image, and linked to a chatbot-like engine in order to discuss directly with the visitors. Stelarc's artworks development is supported by the MARCS Auditory Laboratory in the University of Western Sydney. This team has transposed the Prosthetic Head into the Articulated Head, a new version that is embodied via a LCD screen attached to an industrial robotic arm; this added a strong level of expressivity to the Prosthetic Head : all facial expressions could be correlated to spatial translations and rotations of the screen, thus approximating the movements of a human head when talking or discussing. Thanks to various sensing devices, the team managed to develop an *attention model*, called THAMBS (Thinking Head Attention Model and Behavioural System), to enhance the effect of presence triggered by the synthetic face.

We quickly realized that the floating cubes of the SAILS project could play the same role as this screen, without the limitations imposed by a fixed stand. Through intensive international collaboration between our teams, we managed to realize a performance during which Stelarc's synthetic head was projected onto a large floating cube, whose movements and displacements in the air conveyed the head's emotions and impressions to the audience, while strongly enhancing the effect of presence of the virtual face.

7. Conclusion

The visitors' relations with the robots, as well as the actors' relations with them, proved a valuable and meaningful source of information and knowledge for the design of HRI procedures. In each performance, the visitors were seeking a contact with the robot, and initiated interaction processes. They may have wanted to test their influence on what they saw as a large machine, or simply test its abilities ; but more fundamentally, what could be gathered from our discussions with them revealed that they were attracted by the strange appearance of these slowly moving cubic organisms to which they would attribute a personality and a kind of proto-consciousness ; and that these artificial creatures put the visitors in touch with the fundamental human desire to communicate, even with an entity whose all elements betray the artificial nature.

It has also been observed that a slow moving cube was creating more positive feelings: visitors who accidentally triggered brisk reactions from one aerobot were generally impressed, and even afraid, when they realized that they were the cause of it. These reactions by neophytes proved quite informative in setting a preliminary common ground [4] for optimizing human-robot communications.

The development of interactions for performances followed a different path, since the performers had to get acquainted with the unpredictable reactions of the cubes that were caused by the parameters of the flight environment. This can be seen as a problem from an engineer's point of view: the repeatability and reliability of interactions are almost always essential for any technological applications. Things are very different in art; in this project, unpredictability may become a key ingredient in the definition of each cube's personality. Interactions whose repeatability ranges from "nearly precise" to "moderately imprecise" add to the poetic dimension of the cube, facilitating their assimilation to living organisms. These last observations leads to one of the main conclusions of this paper : endowing robots with basic sensory and interaction aptitudes, and putting them in close contact with humans in a given context and an intentional frame, provides a wealth of observations and data that can be fruitfully exploited for the design of optimal human-to-robot interactions.

From their artistic origin, [5] and throughout all the artistic development that surrounded their technological evolution, the flying cubes demonstrate how several disciplines can contribute to the creation of objects that escape any attempt for classification, and hover over the undefined territories that stretch around the borders between arts, science and technology. We will borrow our conclusive sentence to the late Stephen Wilson : «Artists should be hungry to know what researchers are doing and thinking, and scientists and technologists should be zealous to know of artistic experimentation.»[6]

THE GENEALOGY OF A CREATIVE COMMUNITY: WHY IS AFTERNOON THE “GRANDDADDY” OF HYPERTEXT FICTION?

Jill Walker Rettberg

This brief paper will question the role of the mythical progenitor in the creation of a creative community. Are certain kinds of work more likely to be adopted as progenitor of a field, or does the choice of progenitor depend more on social networks, modes of distribution or even chance? Would electronic literature have been different today if Nichols or Malloy had been crowned as the grandparent of the field?

Granddaddy

In 1992, Robert Coover famously called Michael Joyce’s *afternoon, a story* (1990) the “granddaddy of full-length hypertext fictions” (Coover 1992), writing only five years after *afternoon* was first presented in public (Bolter and Joyce 1987). Since then, both *afternoon* and Coover’s description of it have been cited repeatedly in accounts of the history of electronic literature, whether in books, articles or teaching. *Afternoon* has been canonised by scholars, who reference the work far more frequently than any other work of electronic literature, by teachers and even, quite early on, by mainstream literary institutions, as it was included in the Norton’s anthology *Postmodern American Fiction* in 1998. How did we come to accept *afternoon* as the unequivocal “granddaddy” of electronic literature (not just full-length hypertext fictions, as Coover in fact wrote)? Although earlier works are regularly mentioned when scholars and teachers recount the history of electronic literature, *afternoon* has certainly become the reference point and is frequently assumed to be the first work of “real” electronic literature. This amplification and reinforcement of certain ideas, works and citations is typical of a print-centric culture, Elizabeth Eisenstein wrote in her history of print (1979), but perhaps we should say, more broadly, that it is typical of a culture such as ours that privileges recorded texts, whether analog or digital, linguistic or visual.

Perhaps *afternoon* is indeed the granddaddy of full-length hypertext fiction, but it is certainly not the sole progenitor of electronic literature. That ancestry is extremely diverse, yet most of it has become almost forgotten, as the more easily accessible and more frequently taught works are referred to more and more often.

Beginnings

It took about twenty years for the early British novel to grow from a point when only five or six novels were published annually to a critical mass with new novels being published more than once a week. As Franco Moretti shows in his book *Graphs, Maps, Tree*, this twenty year timeline can be seen to repeat itself in a range of countries, though with different starting points according to when novels began to be published in that country (Moretti 2005).

Has electronic literature gone through a similar time line? Today, certainly there are new works of electronic literature published at least every week. Twenty years ago, in 1991, hypertext and other genres of electronic literature was not quite new, and although not many of them are remembered, there were at

least dozen or two dozen works being published each year. By 1986, and maybe earlier, five or six works of electronic literature were being published each year, even without including interactive fiction in the count. By the early 1990s, several publishers existed, including Eastgate, Voyager and Electronic Hollywood. With the advent of the web, of course self-publishing became even easier, and a number of on-line journals appeared that published hypertext fictions. By the turn of the century large organizations such as the Electronic Literature Organization, trAce and E-Poetry were established. So if we are to follow Moretti's twenty year time line for new genres, 1986-2006 appears to be a reasonable span.

Where should we set the beginning of electronic literature? Electronic literature began in many places, at many times. In 1952, in Manchester, computing pioneer Christopher Strachey created a love letter generator (Wardrip-Fruin 2005). In 1966, at MIT in Cambridge, Massachusetts, Joseph Weizenbaum created a simulated conversation agent, *ELIZA* (1966). In 1976 Will Crowther, another Cambridge resident who worked at a technology company, created *Colossal Cave Adventure*, the first textual adventure game, which was then further developed by Stanford graduate student Don Woods (Crowther and Woods 1976).

All these early works were created by computer scientists who were playing with the technology. They did not see themselves as authors, on the contrary, Strachey, Weizenbaum and Crowther all expressed surprise at their experiments being taken seriously by people. They had not intended to create a new form of literature, and were not, as far as we know, building on or even aware of other work in the field. Their work did not immediately start an avalanche of new literary forms. Indeed, they are only recognised as the starting points of electronic literature in hindsight (Wardrip-Fruin 2005).

Alongside the experiments created by computer scientists there were non-linear literary experiments that have also been seen as "proto-hypertexts", and as the starting points of electronic literature – but these were far and few between. Frequently cited examples include Nabokov's *Pale Fire* (1962), Saporta's *Composition No. 1* (1963), Cortazar's *Hopscotch* (1998) and Pavic's *Dictionary of the Khazars* (1988). Works by visual artists such as Len Lye's animated texts in film (1937) or Jenny Holtzer's *Truisms* (1977) could also be included.

But none of these works was seen as connected to other works at the time. Although they are important in hindsight, they did not shape a community of electronic literature.

One community of experimental, electronic literature and art in the 1980s met on the WELL. Video and performance art curator Carl Loeffler coordinated the Art Com Electronic Network (ACEN) on The WELL where ACEN Datanet, an early online publication, would soon feature actual works of art, including works by John Cage, Jim Rosenberg, and Judy Malloy. Rosenberg's programmatic poetry *Diagrams No. 4* were published here, as was Malloy's database narrative *Uncle Roger*, which was "a hyperfictional narrative database". Malloy's works were also exhibited in physical art exhibitions.

On the opposite coast of the US, introductions were made through shared friends, by reading papers and journals and at conferences (such as the MacAdemia conferences in Philadelphia in 1988 and at Brown in 1989) and the ACM Hypertext conferences in 1987 and 1989. Stuart Moulthrop describes how at the '89 Hypertext conference he and John McDaid, Michael Joyce and Jay Bolter sat at a computer connected to the internet and searched for other people doing similar things. They found Judy Malloy's work:

It was just like blues men going to each other's performances. Yeah, alright, oh darn that's good. Oh, we're not that good. So we really recognized that she was somebody, and she was part of a community out there in the Bay Area that was really important and exciting. I can remember coming away from that moment thinking that, you know, there might be a real hope for what we were trying to do because other people were doing it. (Rettberg 2011)

In an interview with Ransom Center archivist Gabriela Redwine, Michael Joyce described how he came to realize that there was a community of readers passing works around informally even before there was a publisher or any of the institutions that conventionally support literature:

So—you had a physical community [of readers], like a book community. Same thing—similar story—with Jane [Yellowlees] Douglas when she first called me up and said I'm writing my dissertation on *afternoon*. I said, "That's impossible, you can't be, it's not published." She said, "Well, no, but I have it, you know. I've gotten it through so-and-so." So we were pretty much aware there was a community of readers out there. (Redwine 2009)

By the late eighties, several tools were available for creating electronic literature, including HyperCard and Storyspace. Additionally, many practitioners did their own programming, such as Nichols, Malloy and Rosenberg.

Eastgate became a central node in the hypertext fiction communities, as the primary publisher of literary hypertext. In an interview with Judy Malloy, Bernstein explained that he saw one of Eastgate's goals as providing shared references for the growing hypertext research community. The hypertext research field was growing, but before the web it was characterised by diverse, locally developed authoring systems. By publishing a series of hypertext fictions written in the same system, Eastgate managed to create a shared set of references: "These hypertexts helped focus discussion. For the first time, if you and I wanted to talk about the craft of hypertext writing, we could talk about a specific work we'd both read, a work with some ambition and scope, a work we could admire and with which we might disagree" (Malloy and Bernstein 2010).
